This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

ORGAN (Ὄργανον, Gr., *organum*, Lat., an instrument), the noblest of musical instruments, whether considered in regard to the grandeur and beauty of its sounds, the variety of its powers, or the sacred purposes to which it is usually dedicated. It consists of a vast number of metallic and wooden pipes, divided into different *stops*, the wind being admitted into the pipes from a bellows, and is played on by means of a key-board. The machinery of an organ, which is rather complicated and exceedingly curious, has been described in the preceding article.

Originally the word *organum* had a very extensive meaning, and signified nearly every kind of instrument, for whatever purpose employed. By degrees it was confined to instruments of music; afterwards it was applied only to those of the pneumatic, or wind, kind; and finally it was exclusively used to designate that 'world of sounds' which we call the Organ. It can hardly be doubted that this instrument may be traced to Pan's-pipes, or the Syrinx. It must soon have been discovered that the air may be forced into a closed cavity, and then distributed at will to one or more tubes; and pursuing the contrivance a little farther, something like a modern organ was likely to be produced. Indeed Mersenne, in his *Harmonie Universelle*, mentions an antient monument in the Mattei Gardens in Rome, on which appears the representation of a pneumatic organ. It is a small chest placed on a table. In the front is a female figure playing on a number of keys, and on the other side is a man blowing into the box with a pair of bellows exactly like those in present use. In Hawkins's *History* (i. 381) is an engraving of this, from a copy found among the papers of Haym, the author of a history of antient medals. St. Augustin, in his Comments on the 56th Psalm, alludes to instruments inflated by bellows. In the same passage he also gives us to understand that *organa* was a generic term, including every species. 'Organa,' he says, '*dicuntur* omnia instrumenta musicorum,' &c.

The descriptions left us by different authors of the musical instruments of the early part of the middle ages, and the representations of them on several monuments, prove that attempts were made at several periods to improve them. Much thought was expended in discovering the best method of introducing air into the pipes of their organ. For this purpose a fall of water was employed, and also what must be understood to have been steam. William of Malmesbury describes the manner in which the latter was used. He says, 'The wind, being forced out by the violence of the hot water, fills the whole cavity of the instrument, which, from several apertures, passing through brass pipes, sends forth musical notes.' At length bellows were employed for the purpose, which were either worked by water or by hand. The application of these two powers led to the distinguishing terms *hydraulic* and *pneumatic*, or water-organ and wind-organ; though, in point of fact, the ultimate result was the same in both. The inventor of the former, which historians call an *hydraulicon*, is ascribed to Ctesibius of Alexandria, who lived about B.C. 120-120. [CTESIBIUS.] Vitruvius is the first writer who gives any account of an organ of this kind.

The period when the organ was introduced into the churches of Western Europe is very uncertain. Pope Vitalian is supposed to have been the first to admit the instrument, about the year 670; but the earliest account to be at all relied on, of the introduction of this instrument in the West, is, that about the year 755 the Greek emperor Copronymus sent one as a present to Pepin, king of France. In the time of Charlemagne however organs became common in Europe. That prince had one built at Aix-la-Chapelle, in 812, on a Greek model, which the learned Benedictine, Bedos de Celles, in his vast but useful and excellent work, *L'Art du Facteur des Orgues* (1766), considers to have been the first that was furnished with bellows, without the use of water.

Before the tenth century organs were not only common in England, but exceeded, both in size and compass, those of the Continent. St. Dunstan gave one to the abbey of Malmesbury, in the reign of Edgar. Elfeg, bishop of Winchester, obtained one for his cathedral in 951, which was the largest then known. This is described, in eight Latin verses, by Wolstan, the learned monk of Winchester, in the tenth century, of which Mason, the poet, in his *Essay on Instrumental Church Music*, gives the following translation:—

> 'Twelve pair of bellows, rang'd in stated row,
> Are join'd above, and fourteen more below:
> These the full force of seventy men require,
> Who ceaseless toil, and plentifully perspire;
> Each aiding each, till all the wind be prest
> In the close confines of th' incumbent chest,
> On which four hundred pipes in order rise,
> To bellow forth that blast the chest supplies.'

The translator adds an explanation by no means unnecessary: 'We are not,' he says, 'I think, to imagine that these stout bellows-blowers kept their bellows in action all the time the organist was playing. I rather think that his performance did not commence till they had filled the chest completely with wind, which he was afterwards to expend by due degrees, as he found occasion.'

The organ was at first very rude in its construction, and extremely limited in its means. The keys were four or five inches broad, and must have been struck by the clenched hand, in the manner of the carillons: the pipes were of brass, harsh in sound, and the compass did not exceed a dozen or fifteen notes in the twelfth century; and to accompany the plain-chant, no more were required. About that time half notes were introduced at Venice, where also the important addition of pedals, or foot-keys, was first made in 1470, by Bernhard, a German, to whose countrymen we owe many improvements of the instrument; though in excellence of finish they have been surpassed by our English builders.

Few particulars are recorded concerning the organs of this country, from the Reformation to the time of Charles I. Camden mentions one at Wrexham, and Fuller has been strangely misguided in describing it to have had pipes of gold. It shared the general fate of organs in 1641; and the old York organ, lately replaced by a new instrument, was one of the very few that escaped the *organoclasts* of those times. At the Restoration it appeared that only four organ-builders of eminence survived, a circumstance which led to the introduction of foreign artists,—of Bernard Schmidt (commonly called *Father Smith*), and his two nephews, with the elder Harris, and his son Renatus. An account of the dispute between these two family parties is amusingly related in Burney's *Hist.*, ii., 437. Each erected an organ in the Temple church, as a trial of ability: Blow and Purcell displayed Smith's, and Mons. Lully (not the great composer) that of the Harris's. The lord chancellor Jeffries at length decided in favour of Smith. The principal organs of the latter are—the Temple; Christ-Church and St. Mary's, Oxford; Trinity College, Cambridge; St. Margaret's, Westminster; St. Clement's Danes; Southwell Minster; Trinity Church, Hull; and St. Paul's Cathedral. Harris's organ, after being rejected by the Templars, was divided; part was erected in St. Andrew's, Holborn, and part in Christ-Church, Dublin. This last portion was afterwards removed to Wolverhampton. His other principal instruments are those at St. Mary-Axe; St. Bride's; St. Lawrence, Cheapside; and Doncaster. He however, from some unexplained cause, was commissioned to make twice as many organs as his competitor. The *Spectator*, No. 552, says that he was ambitious of building an organ for the metropolitan cathedral. We have however no reason to regret that his wish was not gratified.

To these celebrated mechanicians succeeded Schreider, Smith's son-in-law, who built the organ in Westminster Abbey, and that at St. Martin's-in-the-Fields, the latter a present from George I. as churchwarden; Snetzler, Byfield, &c.; and at a later period, Green; Avery, who most successfully imitated Smith; Gray, Elliot, &c.

The tone of the pipes of the old builders—depending on what is technically called the *voicing*—has never been excelled by later makers; but in point of *touch*, and mechanism generally, the moderns are much superior to their predecessors. In mechanical skill and delicate finishing the English organ-builders far surpass their continental rivals, while in tone they at least equal them; but the costliness of our materials and high rate of wages render the organs of this country much more expensive than those of Germany, or even of France; though the profits of the builders do not bear the same proportion to their prices that is thought reasonable in most other manufacturers. It has been truly observed, that 'notwithstanding the imposing enumeration of so many stops, the large organs of the Continent are inferior in the choice and variety of them to the best English instruments;' a part being in fact but half-stops, and several only absurd imitations of other musical instruments, and rarely, if ever, used by scientific organists.

The following is a list of some of the largest and most celebrated foreign organs, from Crosse's *Account of the York Festival*, 1823, 'collected,' he says, 'from many sources, and enriched with some additions communicated by the Rev. C. I. Latrobe.'

	Stops.	Pipes.
Seville cathedral	100	5300
Goerlitz, in Upper Lusatia	82	3270
Hamburg, St. Michael's	67	
(9 pipes of 16 feet, and 3 of 32)		
Amsterdam, the old church	64	
Weingarten, a Benedictine monastery in Suabia	60	6666
(7 pipes are of 16 feet, and 3 of 32)		
Tours cathedral	60	
Haarlem	60	5000 nearly
(8 of these pipes are 16 feet, and 2 of 32: the greatest diameter being 15 inches. It is 108 feet high, and 50 broad.)		
Alost	53	
Berlin, St. Peter's	50	
Vienna, St. Michael's	40	
Rome, St. John Lateran	36	
Baltimore, in America	36	2213

Mr. (now Sir John) Barrow, in his 'Tour' (1830), mentions a new organ erected in the church of St. Lawrence, in Rotterdam, containing 5500 pipes, which, according to his calculation, is 150 feet in height.

Our English church-organs are numerous, and generally well toned. Though we have none Containing so many nominal stops as a few on the continent can boast, yet we possess some which, in regard to the greater calibre of the pipes, and power of every kind, surpass any foreign instrument. Chief among these are the new organ in York Cathedral, and that in the town-hall of Birmingham.

rk organ, built by Elliot and Hill, contains 56 hrough, besides 6 copula stops. The number 4200. The largest metal pipe is 32 feet in 20 inches in diameter; the largest wooden pipe long, 3 wide, and 2½ deep. This, the builder boasts, would contain twelve pipes and two gallons of wine. Both pipes give c, three octaves below the second space in the base. It has 3 rows of keys, and 2 octaves of pedals. The width of this instrument is 70 feet, and its height in proportion. The old York organ, burnt in 1829, was the largest in the kingdom; it had 3254 pipes distributed among 52 stops.

The Birmingham organ, built by Hill, and completed in 1836, is, as regards size and power, the rival of that at York, though the latter is superior in both, but not in quality. This is 35 feet wide, 15 deep, and 45 high. The swell box alone is the size of a moderately large church-organ. It has 40 real stops, about 3000 pipes, 4 rows of keys, and 2 octaves of pedals. The largest metal pipe is 35 feet long, and 21 inches in diameter, formed, as all the metal pipes in this instrument are, of zinc only. The weight of the whole is about 40 tons.

The organ in St. Paul's cathedral contains 1797 pipes, divided into 28 stops; 3 rows of keys, 2 octaves of pedals, and the largest pipe is 22 inches in diameter. That in Westminster Abbey has 28 stops, and 1524 pipes; 3 rows of keys, and double diapasons for the pedals. At Exeter is an organ, built by John Loosemore, in 1666; its largest pipes are 15 inches in diameter. The organ at Lynn, made by Snetzler, has 30 stops, and among them is a *dulciana*, there first introduced. Green built those at Canterbury, Windsor, Lichfield, and Salisbury. That in King's-College Chapel, Cambridge, was built by Avery. The organ at Yarmouth, erected in 1740, has 29 stops. St. Peter's, at Leeds, contains the same number, with 3 rows of keys, built by Messrs Greenwood of that place. The new church of St. Luke, Chelsea, has been provided with an organ, made by Nicholls, containing 33 stops and 1876 pipes. But the largest instrument in London is that of St. Sepulchre, which contains 2500 pipes, divided into 40 stops; though when that at Christ's Hospital (made by Hill) is finished, it will be much superior, in number of pipes and power, to any in the metropolis. The large organ in St. Patrick's, Dublin, was taken in one of the ships of the Spanish Armada, and presented to that cathedral by queen Elizabeth.

The *Barrel-Organ* is an instrument by which most of the effects of a small keyed-organ are produced by certain machinery. Instead of keys for the fingers, the keys, if so they may be called, are inside the organ, and acted on by means of a cylinder, or barrel, *pinned*, or studded, in a particular and singularly curious manner. This barrel is made to revolve by a winch, and in those of an expensive kind by wheel-work moved by a spring.

The Apollonicon is an instrument which combines in itself the keyed and barrel organ, and which has delighted and astonished all who have heard it. The Apollonicon to which we allude, will, we fear, soon be either removed from this metropolis, or be 'resolved into its elements.' As some description of it may hereafter be found useful, as a part of musico-mechanical history, we refer the reader to the article APOLLONICON, and to the *Harmonicon* (ix. 9).

(Mersenne; *L'Art du Facteur des Orgues*; Hawkins; Crosse's *York Festival*; Millin; *Harmonicon*.)

O'RGANON. It is not possible to give a definition of any science which shall convey its full import, and particularly to a person who does not already know what it is. This difficulty will be experienced by any one who attempts to give a definition of Logic. Without then attempting a definition, or admitting the completeness or correctness of any definition hitherto given, it may be sufficient, for the purpose of showing what that matter is about which we are discoursing, to say that logic is conversant about the formal laws of thought, and that it is not conversant about the matter which is subjected to such laws.

This thing, whatever it may be, about which logic is conversant, is presented to us, and is considered by us generally under the form of language. Whatever are the operations of the mind which are involved or contained in the exercise of thought, those operations may be generally expressed by language. It is assumed here, that by whatever names we designate the relation of the various consecutive and connected trains of ideas which pass through the mind, this relation is in all minds essentially the same. When two persons then possess a common language, one of them can express in this language, with a certain degree of accuracy, the various consecutive and connected trains of ideas which have passed through his mind with respect to any matter or matters. Another person, who, to use the common expresman, understands this language, can, through this medium, communicate with the other person's mind; and if the expression of such ideas has been accurately made according to the form of the language, and if they are properly interpreted, the person who hears or reads what the other has written or said, may in his own mind perceive the same variety [illegible] and connected trains of ideas which the writer or speaker has experienced. If language can effect this, it follows that the mental operations or processes in the two individuals are connected and assimilated by virtue of their both being conformable to the same general laws. It is however the laws of thought about which logic is concerned, and with language no further than as being the form of expression in which the thoughts of others are made known to us, and by which we are enabled to compare those thoughts with our own.

Under the article LANGUAGE it has been stated in a general way what language is; but mainly as to the materials of which it is composed. It remains now to consider its form.

What is called a *sentence* comprehends in its simplest form a subject and a predicate, with something by which a relation between the subject and the predicate is expressed. 'Men die' is a sentence, in which 'men' is the subject, of which 'dying' or 'death' is predicated; that is, in this sentence a judgment is expressed. The sentence indicates that two notions are present to the mind, 'men' and 'death.' What the relation is which the mind really contemplates between these two things, and how it is possible for the mind to contemplate this or any other relation between two things, belongs not to the present inquiry, nor to the province of logic. It will be sufficient to observe, that this judgment or relation does not express or mean, as some writers say, an *agreement* or *disagreement* between the two notions, or that one of them belongs or does not belong to the other; nor is it the *comparison* in the mind of these two notions, at least, logically considered, it is not the comparison in the mind of the two notions as to the matter of them.

The sentence 'men die' may also be expressed thus—'men are mortal;' where mortal is the predicate. The grammatical relation between 'men' and 'mortal,' which is the visible representation of that conceived by the mind, is expressed in our language by the substantive verb 'are,' which is accordingly, in such sentences as this, called the copula. In some languages, as the Latin and Greek, which are rich in terminations, the relation between 'men' and 'mortal' is thus expressed by a termination attached to the word 'mortal,' in addition to the copula, as 'homines sunt mortales;' and sometimes the copula *est* is omitted. When there is not a copula, either in the form of the verb 'to be' or in some other verb of equivalent meaning, the copula is either expressed solely by the order of the words, which is the case with those languages which, like the English, have few terminations, or the copula is expressed by a verbal termination which has a certain relation of fitness to the nominal termination, as in Latin and Greek, and in some cases by the order of the words also, as 'homines moriuntur.' The copula in itself has no meaning: its office is to indicate that the subject and the predicate of the sentence are contemplated as one and each in some relation to the other, in that operation of the mind of which the words 'men are mortal' is the visible or sensuous sign. But the subject itself may be qualified by an attribute, or the generality of the subject (which according to the common interpretation of language is universal when it is not limited) may be restricted or limited by the use of appropriate words, as, 'dying men are prophets,' or 'some dying men are prophets.' Again the predicate may in like manner be qualified or limited; as, 'he writes,' 'he writes a letter,' 'he writes letters sometimes.' Thus every sentence, however complicated it may appear, is reducible to the form of subject, predicate, and copula. 'A tall man on horseback in complete armour was seen crossing a deep and rapid river on a winter's day,' and other sentences of the kind with which ordinary books of narrative abound, may all be reduced to a simple form. It is true that the number of different things or notions which such a sentence brings before the mind often create a degree of confusion, and render the apprehension of the affirmation or negation, which every simple sentence contains, a matter of some difficulty; and this is particularly the case when a sentence so constructed brings before the mind not material objects with which we are familiar, but [illegible] of pure thought, which are not subject to the [illegible] of the senses. And hence it happens that argumentative discourse is not always the most difficult to apprehend. Indeed the difficulty of apprehension is sometimes greatest when the discourse consists of a long series of propositions in which under one set of circumstances one thing is affirmed or denied, or commanded or forbidden; and under another set of circumstances other things are affirmed or denied, or commanded or forbidden; or when things are stated, affirmatively or negatively, with a great many exceptions and limitations. A perusal of a modern act of parliament will show that this is so.

Sometimes there may appear to be, and in fact may be, a difficulty even in a very simple sentence, as to the resolution of it into subject, predicate, and copula. The discussion of this matter belongs to the doctrine of propositions; but so much may be here said, that so far as all propositions are contemplated in their formal and not their material character, they agree in this, that the subject is viewed as something either co-extensive with or included in the predicate. Both the form of language and the form of thought of which language is merely the expression forbid us to contemplate a subject in a greater extent than its predicate. The sentence 'I hope to succeed' is thus reduced (Whately's *Logic*, p. 59):—

$$\overbrace{\text{To succeed}}^{\text{sub.}} \quad \text{is} \quad \overbrace{\text{what I hope}}^{\text{pred.}};$$

which is the same thing as 'success is my hope;' and the remark is made 'that an infinitive (which the author has already defined to be a noun substantive) is never the predicate, except when another infinitive is the subject.' But we may just as well express the proposition thus:—

$$\overbrace{\text{What I hope}}^{\text{sub.}} \quad \text{is} \quad \overbrace{\text{to succeed}}^{\text{pred.}};$$

that is 'my hope is success.' Now as both 'hope' and 'success' are general terms, that is, are words capable of being applied severally to an infinity of particular things, and as neither hope nor success are conceived by the mind in any relation of subordination to one another, as that either of containing or contained, or of species and genus [GENUS], it is indifferent whether we use the phrase *my hope* (sub.) is *success* (pred.), or success (sub.) is my hope (pred.). But this sentence, we conceive, would by most people be reduced thus:—

$$\overset{\text{sub.}}{\text{I}} \quad \overbrace{\text{hope to succeed}}^{\text{pred.}};$$

where 'hope of success' is that which the subject, ego, predicates of itself, that is, these words indicate a mental operation in which the subject (it matters not whether contemplating itself or contemplated by another) is viewed (logically) simply as *within* certain limits of predication.

Every simple sentence which is intelligible is reducible to the form A is or is not B; but it should be observed that the former sentence has two meanings, as already observed. It may mean either that A is contained in B, or that A is co-extensive with B, where A is the subject, and B the predicate, and *is* the copula. It is important to bear in mind this double meaning of the sentence 'A is B.' If it should be said that 'A is B' may also mean 'A contains B,' we can then say that B is contained in A; and so we are where we were before. In ordinary language the ambiguity of the form A is B is sometimes removed by words of limitation, as 'all,' 'every,' 'some;' but frequently there are no such words used, and the consequence is ambiguity.

The sentence 'A is not B' may mean either that A is not co-extensive with B, or that no part of A is contained in B, or that some part of A is not contained in B; but this ambiguity also is generally avoided in common speech by the use of words of limitation, or by attaching the negative to the subject. It is obvious that negative propositions are subject to more ambiguity than affirmative propositions. Negative propositions have given logicians much trouble, and it is clear that we only obtain a clear notion of their import by a tacit reference to affirmative propositions. In itself a negative proposition has no meaning; by the very supposition of its being negative, it excludes the notion of all significancy; and yet by means of such propositions we attain to knowledge. The Stoics (who seem to have had a logic of their own) called such a sentence as 'Pleasure is not good' an affirmative sentence also: their reasons for this are stated, though somewhat obscurely, by Apuleius. (*Philosophy of Plato*, iii. iii.)

Simple sentences are generally combined in written or spoken discourse in such a manner that the whole meaning of the speaker cannot be reached except by considering two or more sentences together. Sentences may be so combined, either in the way of co-ordination or sub-ordination, but this distinction, which is made by Dr. Becker in his excellent German grammar, though it is applicable to some extent to all languages, is perhaps more particularly applicable to the German language than to our own. Two sentences are combined by way of co-ordination when they are connected by such a conjunction as *and*, as 'he eats and drinks,' where we have two distinct sentences, each of which contains a separate and independent affirmation; but we cannot reach the whole of what is said of the subject 'he,' without contemplating the two sentences together. The conjunction 'but' is also often used to unite co-ordinate sentences, as 'he speaks German, but not fluently,' where the sentence beginning with 'but' limits the generality of the former assertion: and the whole sentence does not differ in meaning from 'he speaks German, and he speaks German not fluently.' Subordinate sentences are connected with the principal sentence in a great variety of ways, among which the union by means of the pronouns and words of pronominal origin is perhaps the most frequent: as, 'I do not know when he will come;' 'he lives luxuriously, while others are starving.'

In both cases, both the combination of co-ordinate sentences and the combination of a subordinate with a principal sentence, certain words are used, which are generally distinguished from other words which connect sentences, by the name of *causal;* such are in English, 'for,' 'therefore,' 'then,' and 'since' (not as words indicating time), 'because,' and some others. All languages have words which correspond in meaning to these words. Now it is the combination of sentences produced by such words as these which generally makes up a large part of discourse, written or spoken. When the discourse is bare narration of facts, it is often little more than a succession of affirmative or negative propositions, but so connected and expressed as to render the discourse more pleasing than if the propositions were enunciated separately and in their simple form; but still not logically connected. Besides the ornament and variety which we are enabled to give by written discourse to mere narrative, there is generally a kind of coherence or sequence in the bare facts of narration, which, when some facts are known, can be anticipated by the hearer or reader, and this again helps to render the language of bare narration less tedious.

But when discourse is not limited to bare narration of facts, it assumes a form which still more interests the hearer or reader, and keeps his intellectual powers in constant exercise. Here the discourse does not barely communicate something from the writer to the reader: it does more; it is constantly addressing itself to those faculties of the reason which the reader and the writer have in common, and it is constantly proceeding on the assumption that a great number of universal propositions are admitted to be true by the reader and the writer. Thus, if we say of a certain man—'he is not liked, because he is presumptuous,' two things are affirmed; first, that a 'certain man is not liked;' second, 'that he is presumptuous.' But by the use of the word 'because,' the writer means to affirm something more than the truth of the two propositions; for we may suppose it possible to affirm many propositions of a man without considering the propositions related to one another in any other way than as all relating to one man as the subject. The words 'because he is presumptuous' are designed by the writer to express some connection with or relation to 'not being liked,' which connection or relation must exist in the mind of all other persons as well as in his own, or it cannot be understood. Now, what is that connection which he and all mankind, and a large part of mankind unconsciously, contemplate when this compound sentence is enunciated? The subject of the whole sentence is some given person or individual who is said 'not to be liked,' a proposition universally intelligible. He is said 'to be presumptuous,' which is also universally intelligible. Now, the word 'because' has this office:—it introduces something to the reader's notice to which the universal judgment of mankind attaches the notion of dislike; something which is followed ' something without which there may be dis- with which there must be dislike; that is, n this sense: the reader does not know the individual spoken of, and therefore does not know that he is disliked till he is told so; but he knows something of that individual, namely his presumption, and he also knows that he dislikes a presumptuous individual. He therefore understands the writer, and he admits that statement which is introduced by the word 'because' as a *reason* (to use the common expression) why the man is disliked. He has in fact assented to the universal proposition that 'a presumptuous man is disliked;' he has already mentally formed for himself a general rule that all presumptuous people are disliked, and it is by virtue of himself and the writer acknowledging this universal affirmation as true, that he collects the writer's meaning. But there is no logical inference here; there is no syllogism.

The speaker or writer might however say, all that he knew of a certain man was 'that he was presumptuous;' and he might add to the sentence, and 'therefore I conclude that he is disliked.' If the reader or hearer assented to the conclusion introduced by the word 'therefore,' he would assent to the following mode of stating what he had heard:—

1. All presumptuous persons are disliked.
2. This man is a presumptuous person.
3. Therefore he is disliked;

which is called a syllogism, and is one of the most common forms of a syllogism, in which the first part, or major premiss, is not expressed. The greatest part of written and spoken discourse is either in this form or in that of a consecutive series of syllogisms, called, by logicians, sorites.

The first two propositions are generally called the *premises*, and the third is called the conclusion; and in such a syllogism everything which is called a conclusion is deduced, or considered as deduced, from two other propositions, one of which, as already observed, is commonly suppressed, but is referred to by such a word as 'because,' 'therefore,' &c. It is however very clear that nothing is *proved* even by a syllogism. In the common form of language something is affirmed particularly as a fact, and something is said in the way of a conclusion. The mind perceives no reason why this conclusion is made in the particular instance, more than it should be in any other given instance of the same kind. But while something is in form concluded particularly, something is by implication affirmed universally. A person not accustomed to analyse his own thoughts may not always be able to discover what is that universal affirmation which contains the particular conclusion; but if the argument, as it is generally termed, be expressed in the complete form of a syllogism, he at once perceives what universal proposition must be admitted or proved, in order that the particular one shall be true; if he has already given his assent to the proposition as stated, without a clear conception of the extent of the admission which he will be considered to have made, he is enabled by means of the syllogistic form to examine more clearly that mental operation which to him was before confused. The conclusion of the syllogism *proves* nothing. as an inference or illation it necessarily follows from the premises, that is, the mind cannot conceive it otherwise; and in this operation it is subjected to laws of thought which are irresistible. When the truth of the premises is ascertained or admitted (which, for the purpose of argumentation, is the same thing) the conclusion, which before was logically correct, now becomes also true. All discourse of the kind called argumentative, indeed all discourse so far as it contains inferences, may be reduced to the form of a series of syllogisms, from which it will appear what universal affirmations or negations are implicitly contained in the discourse. It will also show what universal affirmations or negations are used as a means of attaining to other affirmations or negations which are not true unless the first are true, and which when attained become the premises of other conclusions. Discourse of the argumentative kind has for its object to establish particular things, or things which are comprehended within other things. Particular things, so far as they are the objects of sensuous perceptions, are directly established by evidence, as for instance, the qualities of any material object; but there are many things which are not susceptible of this kind of evidence, and of which there is no evidence but the universal consent of mankind. In an argumentative discourse therefore the writer who has particular things to prove, alleges, expressly or by implication, universal truths, and he affirms, either expressly or by the implication of language, that the particular things are contained within the universal. If the reader assent to the universal truths, and also admit that the particular things are contained therein, the writer accomplishes his purpose, and his demonstration is complete. He is said to have 'inferred something, or to have made a deduction.' If all written or spoken discourse were in the form of perfect syllogisms, there would be little confusion or dispute about what is called the premises and the conclusion, for the whole matter would be so placed before the reader that he would always perceive the general proposition within which it is affirmed that the particular is included. It is then the general condition of every syllogism imperfectly expressed, that when we are speaking of what we call one thing, we are in effect speaking of many things: for that which is asserted of one can equally be asserted of all things of the kind, and it is not possible to conceive it true of one without conceiving it true of all.

Some writers have observed that the causal conjunctions are employed to denote respectively cause and effect, as well as premises and conclusion; as in the following examples:—'The ground is rich *because* the trees on it are flourishing;' or, 'the trees are flourishing, and *therefore* the soil *must be* rich;' where the conjunctions *because* and *therefore* are considered to be used to denote the connection of premises and conclusion. But in the following sentences, 'the trees flourish *because* the ground is rich;' or, 'the ground is rich, and *therefore* the trees flourish;' the same conjunctions, it is said, are used to denote the connection of cause and effect; and it is added that in the latter case 'the luxuriance of the trees, being evident to the eye, would hardly need to be *proved*, but might need to be accounted for;' and as to the former case, it is remarked, 'that the luxuriance of the trees is not the cause of the soil's fertility, but only the cause of my *knowing it*.'

Now in the expression, 'the trees are flourishing, and *therefore* the soil *must be* rich' (if for *must be* we write *is*, which ought to be done), it may be meant to affirm, either that the trees are flourishing, and that the quality of the soil is unknown; or it may be meant that the trees are flourishing, and that the soil also is *rich*. In the former case the richness of the soil is concluded, according to the common expression, from the supposed premiss of the invariable coincidence of flourishing trees and rich soil, and as the world knows or says (which for the present purpose is the same thing) that a rich soil is necessary in order that trees may flourish, the richness of the soil is in fact, according to the common notion of cause and effect, here also considered to be the cause of the luxuriance of the trees, if we look to the matter of the syllogism. In the latter case, if both things are affirmed, both that the trees flourish and that the soil is rich, the same thing is affirmed as in the sentence 'the ground is rich and *therefore* the trees flourish;' and in both these cases, when the two propositions are considered as affirmations, not connected in the way of conclusion, nothing more is effected by the word *therefore* than to suggest the notion of the invariable coincidence of flourishing trees and rich soil.

The Conclusion of the 'ground being rich *because* the trees on it are flourishing' (the richness of the ground in question not being known otherwise than by the trees) cannot be made except from the premiss, 'wherever trees flourish, there the ground is rich.' Now though it may be true that 'wherever trees flourish, there the ground is rich,' it may not be true that 'wherever the ground is rich, there trees flourish,' for the ground may be rich, and covered with water in which trees will not flourish. But if we affirm that 'the trees flourish *because* the ground is rich,' we affirm both 'that the trees flourish' and 'that the ground is rich,' which again is nothing more than affirming by implication that 'wherever trees flourish, there the ground is rich,' leaving it, as before, possible that there may be rich ground where trees do not (for some reason or other) flourish.

Now it is said that in the former case, where a Conclusion is made, the 'luxuriance of the trees is considered to be the cause of my *knowing* the fertility of the soil:' that is, in the conclusion, 'the ground is rich because the trees on it are flourishing,' 'the ground is rich' is my (concluded) knowledge, and *because* is there used to express cause and effect, as between 'flourishing trees' and 'my knowledge.' In the latter case, where both propositions are affirmative, but neither of them in the way of conclusion, it is said that the luxuriance of the trees does not require *proof*, but requires to be accounted for; that is, richness of soil and luxuriance are here considered in the relation of cause and effect. According to this, a relation of cause and effect, though not of the same cause and effect, is indicated in both cases by the word *because*; and in the former case the *richness of the soil* is considered to be *proved* also.

This is rather perplexing, but perhaps the perplexity may be got rid of thus:—'The ground is rich, *because* the trees on it are flourishing,' is necessarily *true*, if it is also true that 'wherever trees flourish, there the ground is rich;' but this *general* proposition must be *proved* in some way or assumed, in order that the logical conclusion may also be a true conclusion. 'The trees flourish *because* the ground is rich:' here both facts are *proved* or assumed (which for the present purpose is the same thing), and it is also affirmed by implication that 'wherever trees flourish, there the ground is rich.' The difference between the two sentences then is this: the former affirms that a particular soil is rich if soil is always rich under similar circumstances; and the reduction of the expression to the complete syllogistic form shows us what must be proved or assumed in order that the conclusion shall be true in this particular case. The latter affirms the particular thing to be true, which in the *former* is only true upon a certain condition; and it also affirms by implication the truth of this certain condition. The *former* is a syllogism, because that which is said of the whole may be said of a part. The latter is nothing more than the implicit statement of a general proposition contained in the explicit statement of a particular instance: it is no logical inference; it is no logical induction; it is simply a statement of a thing being true in a certain case, with an implicit assertion that the same thing is true in all similar cases; in other words, the form of language implicitly contains the affirmation of a general proposition, which can only be the result of an induction in the non-logical sense of that term.

The difference between logical Deduction and Induction is explained in the article INDUCTION. But it will not be out of place to say a few words on the subject here. In the Deductive Syllogism, we proceed from the whole to its parts, from the thing containing to the things or some of the things contained; and this is true notwithstanding it is not so expressed in the common form of language. For the particular conclusion, as already observed, is the thing which in ordinary language is said to be proved; but there is no demonstrative evidence to the mind, except it is shown that the particular conclusion is contained in a general proposition. The deductive syllogism as already explained shows what this general proposition is, and this general proposition is assumed to be true, or is known to be true in some other way (by induction, properly so called, for instance) than by means of the syllogism. But there is another mode of operation by which the mind can proceed from particulars to generals; but this, which may be called the Inductive Syllogism, is no syllogism, that is, no necessary conclusion, unless *all* the particulars are enumerated, or assumed to be enumerated; and in this consists the difference between the Inductive Syllogism and Induction, or what is sometimes, but, we think, not with strict propriety, called Inductive Reasoning, which however is no operation of reason, but one of the understanding only; or, to prevent disputes about terms, it is not the same mental process as that of the Logical Induction, for its conclusion is not necessary. This Induction then, which leads us from the observation of one or more like facts to make a general assertion which will comprehend like facts not observed, is a material illation of quite a different character from the other. This process has sometimes been absurdly considered as a peculiar discovery of modern times, though it must have been practised by the first man who ever made use of his eyes. The process of investigating and collecting facts which are among the phenomena of the material world, has been greatly *improved* in modern times.

That syllogistic form which is properly called Inductive (ἐπαγωγή) is explained, though very briefly, by Aristotle (*Analyt. Prior.*, ii. 23; *Topic.*, i. 12), and is not confounded by him with the material induction of a general law or rule from the examination of a number of particular cases of a like kind.*

If we wish to prove syllogistically the mortality of a given individual John, we say—

All men are mortal;
John is a man;
Therefore John is mortal.

Now this conclusion is necessary, because 'John' is contained in 'all men.' But suppose we wish to prove our primary proposition, that 'all men are mortal,' what is the process that we must follow? We may affirm mortality of all men who have died, but we cannot affirm it of all who are living and who shall live, for that is the thing to be proved. This is a case in which there can be no logical, that is, no necessary conclusion.

---

* Ἐπαγωγὴ μὲν οὖν ἐστι, καὶ ὁ ἐξ ἐπαγωγῆς συλλογισμὸς, τὸ διὰ τοῦ ἑτέρου θάτερον ἄκρον τῷ μέσῳ συλλογίσασθαι.

Dr. Whately says (p. 229) 'that in the process of reasoning by which we deduce from our observation of certain known cases an inference with respect to unknown ones, we are employing a syllogism in barbara with the major premiss suppressed; that being always substantially the same, as it asserts 'that whatever belongs to the individual or individuals we have examined, belongs to the whole class under which they come.'

And he further says that induction, 'so far forth as it is an *argument* (which has previously, in the same work (p. 55), been defined to be a 'syllogism when regularly expressed'), may of course be stated syllogistically; but so far forth as it is a *process of inquiry* to obtain the premises of that argument, it is of course out of the province of logic.' But a syllogism will be equally good (p. 14) if we substitute arbitrary symbols for the terms, without any regard to the things signified by them; and (p. 23) 'every conclusion is deduced from two other propositions or premises.' This so-called induction then, stated syllogistically, turns out to be nothing different from a proper syllogism: if the premises are true, the conclusion is necessarily true. The syllogism then has done nothing, and it leaves the process of inquiry precisely where it was before the induction was put into this so-called syllogistic form.

This mistake requires a few more words, as it has been declared to be 'a just, and, so far as we are aware, an original remark; and its consequences are extremely important.' (*Westminster Review*, No. 17, p. 169.)

The deducing an inference from facts investigated and collected is said to be an argumentative process, and, like other arguments (that is, syllogisms), capable of being syllogistically expressed. If it is a syllogistic process, it is undoubtedly susceptible of the strict syllogistic form. Now this so called inference is the making a universal affirmation founded on a number of particulars; and if it is a syllogism, the universal affirmation is the conclusion; and if it is a syllogism, the conclusion is necessary. The conclusion is by the supposition a conclusion from certain known things as to other unknown things; and the universal conclusion is, that something is true of the unknown things which is known to be true of the known ones; in other words, that this something is true both of the known and the unknown things. Now in order to attain this syllogistic conclusion, it is said that we employ a syllogism, in which the major premiss is of this form: everything which is true of the known is true of the unknown, or everything which is true of the known is true of the known and the unknown.

To take Dr. Whately's own example: 'from an examination of the history of several tyrannies, and finding that each of them was of short duration, we conclude that the same is *likely* to be the case with all tyrannies.' And it is said that in such syllogisms as these, we assume 'that *whatever* belongs to the individual or individuals that we are examining belongs to the class under which they come.' Now this universal affirmation is a proposition *to be proved* in some way or other. If it be assumed, it is the major of a deductive syllogism, and the conclusion is logically necessary, and also true, if the major is true. But how is this major to be established, by virtue of which we are to have a logical illation and a true conclusion? It is admitted that in induction, properly so called, a general material truth is to be affirmed by virtue of *particular* facts being investigated and known. But if we affirm some proposition which is more general than and comprehends that which we wish to establish, and then so construct our syllogism that the conclusion shall be a logical inference, it cannot be a true one also unless we establish this more general premiss. But the object of the true induction is to establish the general truth from particular facts that are known and investigated. If, in the case supposed, the syllogism is valid, the particular facts are useless; the conclusion is logically good, and it becomes materially true when the more general proposition is established which contains the conclusion. But it is not the object of the investigation and collection of facts to establish a proposition different from and more general than that for the establishment of which the facts are investigated and collected, in other words, it is not the matter in hand to investigate and collect facts for a particular purpose, and then not to use them for that purpose.

In this so-called syllogism then we have a suppressed major of this form, 'that which is true of some is true of all,' which must mean either 'everything which is true of some is true of all,' or, 'this one thing which is true of some is true of all.' In the former case, the suppressed major expresses a general proposition, which we must establish in order that our illation, which is logically correct, may be true materially; but then this is not the proposition which we profess to be desirous to establish, and, more than that, it cannot be established by the facts investigated and collected. If it means that this *one thing* which is true of some is true of all, this is nothing more than to make the conclusion the major premiss, and so to conclude the conclusion from itself. It cannot be supposed that Dr. Whately has any such absurd meaning as this: but his language is capable of this meaning. He does however mean either this or the other; and it is not easy to say which is the less logical meaning of the two.

A few more words seem necessary on another passage in Dr. Whately's work, by way of clearing the way to a right comprehension of the province of logic. It has been already observed that discourse or speech generally assumes the form of a syllogism with one of the premises suppressed; which is by many modern logicians called an enthymeme.*

Dr. Whately observes that the enthymeme (the enthymeme of modern logicians) 'is *not strictly syllogistic*, i.e. its conclusiveness is not apparent from the mere form of the expression, without regard to the meaning of the terms; because it is from *that* we form our judgment as to the truth of the suppressed premiss. The expressed (qu. *suppressed*) premiss may be true, and yet the conclusion false.' The reason here given why the (so-called) enthymeme is not strictly syllogistic is, that we form our judgment of the truth of the suppressed premiss from the meaning of the terms. This is a singular reason. The *truth* of the suppressed premiss has nothing to do with the validity of the conclusion as an inference. If the suppressed premiss were expressed, the question as to the conclusion would be, not whether the suppressed premiss were true, but whether it necessitated the conclusion. If the conclusion is already made and one premiss only stated, the *truth* of the suppressed premiss is not the matter in question, but only *what* it is; and when we have ascertained what the premiss must be in order that the conclusion may be valid as an inference, we may then inquire if the suppressed premiss is true. The expressed premiss cannot be true and the conclusion false, for the proper suppressed premiss is virtually involved in the conclusion and the expressed premiss. Besides, the mere form of the expression does indicate the suppressed premiss; if it did not, the enthymeme, that is, the incomplete syllogism, the syllogism of common discourse, would be incapable of being expressed in the form of a complete syllogism. If we say A is C, *because* or *for* it is B, which is the mere *form* of the expression, we see that the suppressed premiss is, B is C, that is, B is contained in or is co-extensive with C; and every person who can comprehend the notion of a containing whole and its contained parts will understand what is meant if it is expressed in this form: A is contained in C because A is contained in B. As if a man had found that any one thing could be contained in another (second) thing, and this other (second) thing were contained in a third, he would conclude mentally that this one thing was contained in the third; and the form of his expression would be, it is contained in the third *because* it is contained in the second, in which he would tacitly suppose that the second is contained in the third, and would then necessarily conclude that the first is contained in the third.

We are now in a condition to show what are the limits of pure logic, or of a pure logic. All propositions and all syllogisms are the subject of a pure logic only so far as they have all something in common. They have only something in common so far as they are all capable of being reduced to a common form or forms; that is, a pure logic is formal.

---

* It has been observed by a learned writer ('Edinburgh Review,' No. [illegible]) that this is not the meaning of the enthymeme of Aristotle's [illegible] true, nor is it the meaning of the enthymeme of Cicero. The following passages may be referred to as showing the meanings of the old enthymeme (ενθυμημα), which seems to have been taken by different writers in different senses: Aristotle (Anal. Prior. ii. 27), Cicero (Topica, 13, 14), [illegible] (περὶ Ἑρμηνείας, [illegible]). [illegible] to the modern enthymeme (Comment. in Cic. Topic. [illegible])

[illegible]. Whether the syllogism may in parts regard the mat-[illegible] and the propositions which enter into the syllogism [illegible], the object of logic as far as they are connected [illegible] and is not. And since all propositions when viewed [illegible] as the parts of a syllogism, must be capable of being reduced to the same form or forms, it follows that all propositions as logical elements connected by it and [illegible] are [illegible] to that way in which the reason does, and must because it does, view all things which are so presented to the mind independently of the matter, namely, with relation to the notion of a containing whole and contained parts.

[illegible] this exposition above follows, the fault is with those [illegible], while they profess to teach pure logic, confound it both with an applied logic and with other things also.

There seems to us another error in Dr. Whately which is worth noticing: he says, 'No conversion is employed for any logical purpose, unless it be illative;' and he adds, 'The reader must not suppose from the use of the word "illative," that this conversion is a process of reasoning; it is in fact only stating the same judgment in another form.' Now if we say A is B, meaning that A is contained in B, it is a logical consequence or conclusion, though not a syllogistic one, that B is not contained in A. In this case there can be no unlimited logical conversion of the proposition. If A is coextensive with B, then B is coextensive with A; in which case there is a logical conversion. The laws of thought necessitate the non-conversion in the one case and the conversion in the other; and if these are not logical conclusions, there is no such thing as a pure logic or reasoning.

It is generally said that logic teaches us to reason correctly, or that it shows the process which takes place in the mind when a man does reason correctly. It is however difficult to admit the accuracy of this statement. If a man reasons at all, in the strict logical sense, he reasons correctly. Language is seldom expressed in the form of syllogisms, and it is not usual to express, in any way, both the propositions from which we deduce a conclusion. We generally express ourselves by way of a conclusion and one premise, but this being so, the suppressed premise may always be discovered by analysis, though the speaker or writer may not always be able to discover his own suppressed premise. A conclusion and one premise being given, the suppressed premise is also given, for the conclusion and the expressed premise necessitate the proper suppressed premise. They who say a man argues incorrectly, when he states a conclusion and one premise only, assume that his suppressed premise is not that suppressed premise which the two data require, but some other. But if some other, it is impossible that they can find it out, and therefore they cannot confute him. It is only because the suppressed premise (perhaps not known to the speaker) pointed to by the data, is the false one, that we can confute the speaker. We show what the suppressed premise is, and then we are in a condition to dispute it, and to ask him for proof of it. A man then does reason correctly when he reasons by a conclusion and one expressed premise. The syllogistic form shows us what the premise must be, that is, it leads to the full interpretation of the speaker's meaning. But suppose a man expresses all the terms of a syllogism, and his syllogism is vicious, is it vicious because he reasons wrong, or because he has given a meaning to some of his terms which other people do not, or misunderstands them? We think that his reasoning, as such, is and must be correct. His apprehension may be and often is wrong. In this view, reasoning, as reasoning, is always correct reasoning. It has been objected to this by a friend, that many persons who are not familiar with logical considerations, on being asked whether, if every A is B, every B is also A, will admit this conversion to be true, and that, when asked it, in admitting this, they reason incorrectly. The answer to this difficulty is furnished by the objector. He goes on to say, that if the person who admits this conversion is asked the same question as to a material conversion, such as, every goose is an animal, he immediately perceives that he cannot say every animal is a goose. This shows that his apprehension of the expression, every A is B, was incorrect, that is, he did not understand it, but took the words as meaning something different from what the person intended who put the question.

In argumentation the conclusions are the matters which [illegible] disputed, and the suppressed proposition is [illegible] the real matter in dispute, or the meaning of a [illegible] is the matter in dispute. The use of logical forms consists in showing fully and explicitly what is expressed imperfectly and only implicitly in the common form of language; and its use is not a bit the less because it neither teaches to reason nor convicts our reason of error. Its use is to indicate to us all the formal elements and conditions of dependent truth. It points out to us and leads us to the consideration of the several propositions which discourse contains, and from the consideration of the several propositions it leads to the terms, and there it leaves us.

The cause of this confusion between logic and metaphysic is obvious, and lies in the necessity which all men feel of a metaphysic of some kind or other. General terms and general propositions, the elements of every material syllogism, are deeply fixed in the mind long before its consciousness is awakened to the cognizance of the operations of the reason; and in many minds this consciousness is never called into existence. Logicians clearly perceive the value of the syllogistic forms as an aid and a formal help in analysing the reasoning process in a given case; they also see or feel that the reasoning process in itself is not knowledge, but they see that it is a means to knowledge. Its barrenness in itself is confounded with its productive powers when exercised on a material, and hence they have come to confound its operating energies with its products; as if a man should confound his tools with that which is produced by his tools operating on his materials.

A pure logic will lead all men to a metaphysic, for a pure logic has its use in its applications. A metaphysic, as a system, if it does not contain a logic, will lead to the results of most systems of metaphysics, that is, to none at all.

Thus it appears that the study of logic is perhaps the proper introduction to a metaphysic; and it were much to be wished that all who have written on the latter had first been subjected to the discipline of the former.

The forms of the SYLLOGISM are considered under that article, consistently with the plan of this work. In the mean time, till we have some system of logic in our language which is founded upon and grows out of some philosophical system, it is better for the student to study only a purely formal logic, which is independent of any philosophical system, and to apply it to his various studies. For such purpose, a small pamphlet such as Professor De Morgan's 'First Notions of Logic, preparatory to the Study of Geometry,' London, 1839, seems to us the only kind of book in our language that can be safely recommended.

The question, What is Logic? has been a matter of much dispute. It has also been disputed whether logic is a science or an art, or both—an idle question, which may be safely left undecided. It is more important to determine what is comprehended in the term logic, and this has partly been attempted here. It is also of some importance to show that the notions of this science do not appear to have been very exact among the Greeks and Romans, which may be one cause of the traditional confusion as to the limits of logic which has been so common in modern times. It may be also useful to show what logic is conceived to be by some modern writers.

There is no definition of logic in the extant works of Aristotle; and if we deduce from his Organon, as we now have it, our notion of what the term comprehends, we shall find that it contains a great deal which does not belong to logic as it has been understood by those who have formed the most exact notions of it. If we should attempt to ascertain what logic is from the writings of all who have written on logic, it will be found impossible to form any exact notion of its limits and objects.

Dialectic is distinguished by Cicero (*Topica*, 2) from Topic. 'All exact argumentation,' he observes, 'consists of two parts, one comprehending invention (unam inveniendi), and the other judgment (alteram judicandi).' He assigns to Aristotle pre-eminence in both, and speaks of the Stoics as having especially applied themselves to the latter, which they named Dialectic. But the dialectic of the Stoics was certainly not confined to pure logic, as appears from what Cicero says in his treatise 'On the Orator' (ii. 38), and also from the statement of the Stoical opinions as to dialectic by Diogenes Laertius, in his Life of Zeno of Citium. The Stoic dialectic seems to have comprehended logic and more, as will hereafter appear; and yet it comprehended less than the logic of the Peripatetics.*

---

* See also the threefold division of Philosophy by Diogenes Laertius ([illegible]) into Physics [illegible] Ethics [illegible] and Dialectic [illegible]

In Dr. Whately's treatise, as may be collected from a comparison of various passages, logic seems to be convertible with syllogistic. To *reason*, in the strict sense of the word, is to make use of arguments (p. 18); an argument, when regularly expressed, is a syllogism (p. 55); and logic is the science and the art of reasoning (p. 1): from which it follows that to syllogise and to reason are convertible, and that logic is the theory of the syllogism (p. 73).* This seems to be the meaning of the author, and if such be the proper notion of logic, it must be admitted that the boundaries of the science are very limited indeed. But limited as they really are, in this view of the subject, the exercise of reducing argumentation to syllogistic forms still contains more than those may be inclined to suppose who have not been disciplined in this practice.

It may be worth while to notice what Dr. Whately says of the word *argument*. 'Every argument,' he observes, 'consists of two parts, that which is proved, and that by means of which it is proved;' and he adds in a note, that this is the strict technical sense of the word argument, but that in popular use argument is often employed to denote the latter of these two parts alone. But this is a mistake: the popular use is the correct use, as it is in many other cases. When a man is said to use a good argument, he urges or suggests something which is either proved or universally admitted, and the goodness of his argument consists in its being applicable to the matter in hand, and obviously comprehending within it something which it is his object to establish or prove. He who argues well, possesses the inventive faculty as defined by Cicero. It is his business to establish one or more things, and to command the assent of his hearers by presenting to their minds such propositions as only need to be presented in order to command assent, and which are comprehensive enough to embrace the particular things which he has to establish. The argument, in the popular sense, is the premises of the syllogism; or it is the middle term; and it is accordingly explained by Cicero (*Topica*, 2) to be 'ratio, quæ rei dubiæ faciat fidem,' the *reason*, which gives credibility to a thing that is doubtful. Of course that which is proved or to be proved cannot be an argument within Cicero's meaning of the term. Dr. Whately himself says, 'that which is used to prove the question, if stated *last* (as is often done in common discourse), is called the *reason*.' But it is equally the reason whether placed first or last, and is called the *reason* with strict technical propriety, whatever may be the place which it occupies in discourse. The proper name for the syllogism is argumentation, of which the two premises are the argument; and this is the sense in which antient logical writers understood argumentation and argument.

The meaning of the term Logic is explained by Kant with his usual clearness. Logic is the science of the laws of thought. Logic may be considered from two points of view, as General or Special. General logic comprehends only the necessary laws of thought, without which there can be no exercise of the Understanding, and it has no reference to any difference in the objects to which it is applied. Special logic comprehends the rules of thinking rightly on any given subject. General logic again is either Pure or Applied logic. In the former we abstract from all empirical conditions under which our understanding is exercised, as for instance, the influence of the senses, imagination, memory, &c. A General and Pure Logic has consequently only to deal with pure *à priori* principles, and is a canon of the Understanding and of the Reason, but only in respect to the formal part of its use; the matter which is its object may be either empirical or transcendental. A General Logic is called Applied when it has reference to the rules of the exercise of the Understanding under the subjective empirical conditions, which we learn from psychology. It has consequently empirical principles, though it is so far General that it has reference to the exercise of the understanding without any distinction of objects. In General Logic consequently, the part which comprehends the pure doctrine of the Reason must be absolutely separated from that which is Applied, though still General Logic. The first part only is properly a science, though brief and dry, as the regular exhibition of an elementary view of the Understanding must be. In this science then logicians must always bear two rules in mind:—

1. As General Logic, it abstracts from everything which the understanding contains as knowledge, and from all differences in its objects, and it has only to do with the pure form of thought.

2. As Pure Logic, it has no empirical principles, and consequently derives nothing (as has been sometimes supposed) from psychology, which therefore has no influence at all on the canon of the understanding. It is a demonstrated science, and everything in it must be absolutely *à priori* true. (Kant, *Critik der Reinen Vernunft*, p. 55. &c., ed. 1828.)

By Applied Logic, Kant understands an exhibition of the understanding and the rules of its necessary exercise *in concreto*, namely, under those accidental conditions of the subject which may assist or impede its exercise, and all which are only empirical data. It treats of attention, its impediments and consequences, the origin of error, the state of doubt, conviction, &c.

General logic then abstracts from all our knowledge, that is, from all relation of our knowledge to an object, and contemplates only the logical form in the relation of the parts of our knowledge to one another, that is, the form of thought generally. So far as truth is concerned, since logic is conversant only about the general and necessary rules of thought, the criterion of its truth must lie in these rules; and whatever contradicts them is false, for logic would then contradict itself. Yet though a logic may be consistent, that is, not self-contradictory, yet it may be contradictory to the object; consequently the bare logical criterion of truth, namely, the conformity of knowledge with the general and formal laws of thought and of the reason, is the *conditio sine quâ non*, and consequently the negative condition of all truth. Further however logic cannot go, and any error which affects not the form, but the matter, logic has no means of detecting.

A recent German writer has viewed logic in a somewhat different light, and given it a wider range. The difficulty of presenting anything like an adequate view of the principles of Hegel by a few extracts must be the apology for this imperfect attempt; the obscurity of the exposition, if such it shall appear, may be partly though not entirely due to ourselves.

'That which is generally understood by the term logic, is viewed altogether independent of any metaphysical signification. In its present condition this science has no subject-matter (inhalt) in the sense in which subject-matter is considered as a reality and as a truth in the ordinary acceptation of the term. But it is not for this reason a formal science which is devoid of truth. The region of truth however must not be sought for in that material which people expect to find in logic, and to the want of which its unsatisfactory nature is usually attributed; but the emptiness of logical forms rather lies in the way in which they are considered and handled. So far as logical forms, considered as determinate notions, are disjointed from one another, and not bound together in organic unity, they are dead forms, and have not in them the spirit which is their living concrete unity. Thus viewed, they have no solid subject-matter (inhalt)—no matter which of itself would be a real substance (gehalt). The subject-matter which is looked for in logical forms is nothing else than a firm foundation and concretion of these abstract determinations; and such a substantial essence is usually sought for beyond the bounds of the science. But the logical reason is itself the Substantial or Real matter, which unites in itself all abstract determinations, and is their solid absolute concrete unity. There was no need then to look far for a subject-matter, as it is usually called; it is not the fault of logic if it appears empty, but it is the fault of the way of considering it.'

'In forming judgments and conclusions, when the operations are especially referred to and grounded on the quantity of the notions, everything rests in an external difference, in a mere comparison, and becomes a pure analytical process and calculation void of all ideas. The deduction of the so-called rules and laws of conclusions in particular, is not much better than a handling of sticks of different lengths in order to sort them out and tie them up according to their magnitude—nothing else than the child's game of selecting and putting together the pieces of a picture which is composed of parts. This exercise of thought has accordingly has hardly been compared with arithmetic, and arithmetic has been compared with it. In arithmetic, numbers are considered independent of any notions, as something which, independent of their equality or inequality, that is independent of their absolute external relation, has no signification, as something which neither in themselves nor in their relations express a thought. When it is mechanically ascertained that ¾ multiplied by ⅔ make ½, this operation contains just as much and just as little thought as the ascertainment whether in a given figure this or that conclusion can be made.'

---

* Dr. Whately says, 'The third operation of the mind, namely, reasoning (or discourse) expressed in words, is *argument*; and an argument, stated at *full* and in its regular *form*, is called a syllogism; the third part of logic treats of the *syllogism*.' The other two parts, which are briefly y Dr. Whately, are—c. 1, 'Of the operations of the mind and of nd c. 2, 'Of propositions,' but they are very incomplete, and, as we y deficient in logical precision. There is a Supplement to c. 1.

Hegel remarks, that with respect to the formation of an individual mind, logic may be compared with grammar. Both logic and grammar are something different for him who first approaches them and science in general, and for him who comes back from the sciences to them. He who begins to learn grammatical forms and rules, sees in them nothing but themselves: he who has mastered a language, and compares it with other languages, is in a capacity to understand the full force of these rules and forms. Through the grammar he can reach the expression of the mind, the logic. The case is the same with a man's first introduction to logic: its signification is limited to itself. Logic must be first learned as something which a man comprehends and understands, but in which extent, depth, and further meaning are not discovered. It is not till we have a deeper acquaintance with the other sciences that the logical becomes for the mind, subjectively, not a mere abstract universal, but a universal which comprehends within it the abundance of the particular: just as the same moral maxim in the mouth of a youth, even if he understands it correctly, has not the signification and the comprehensive meaning which it has in the mind of a man of long experience, to whom the words convey the full force of the expression. Thus the logical cannot be fully estimated until it is made the result of experience in the sciences: it then presents itself to the mind as the universal truth, not as a particular knowledge co-existent with other matter and realities, but as the essence of all other knowledge.

'Logic has been defined (by Hegel) as the science of the pure thought, which has for its principium (princip) the pure knowledge (wissen); not an abstract, but a concrete living unity; and concrete in this way, that in it there are inseparably opposed to one another the consciousness of a subjective self-existence, and a second such existence, an objective; and that existence is known as a pure Notion in itself, and the pure Notion is known as the real existence. These then are the two moments which are contained in the logical. But they are only known as existing inseparably, and not each in the consciousness as existing by itself; but it is only by virtue of their being also known as different (yet not self-existing) that their unity is not abstract, empty, and inactive, but concrete.

'That unity constitutes the logical principium (princip) as the element, so that the development of this difference, which is always in it, takes place *within* this element. Thus the entire notion is to be considered in the one case as existing Notion, in the other as Notion simply; in the former case it is notion by itself of reality or existence; in the latter it is notion as such, self-existing notion.

'Logic will therefore be divided into the logic of the notion as existence, and of the notion as notion; or, to make use of the common though very indefinite and ambiguous expressions, into the objective and subjective logic.

'Consistently with the fundamental element of the unity of the notion in itself, and the connected inseparability of its moments, these moments must be viewed also in their mutual relations, so far as they are different, and so far as the notion is considered with respect to a difference. Hence arises a sphere of Mediation (vermittlung), or of the notion as a system of reflective determinations, that is, of the existence passing into the internal existence of the notion, which, in this way, is not viewed as such *by itself*, but is affected by the immediate existence as by a thing properly external to itself.' This is the doctrine of the essence (wesen), which stands between the doctrine of existence and of the notion; but in the general division of Hegel's work it is placed under the objective logic, inasmuch as, though the essence is certainly the Internal, yet the character of the subject is expressly appropriated to the Notion.

Hegel's division therefore is into the objective and subjective, or, more distinctly, into:—

1. The Logic of Existence (Die Logik des Seyns).
2. The Logic of Essence (Die Logik des Wesens).
3. The Logic of the Notion (Die Logik des Begriffs).
(*Wissenschaft der Logik*, erster band. 1812.)

It may be useful to shew in a general way what the Organon of Aristotle, as we now have it, contains. The name Organon, or Instrument, was not given by Aristotle, but is of a date posterior to him.

The following synopsis is given by Giulio Pace, in his edition of the Organon:—

Logic is conversant about the Syllogism. Accordingly the Organon explains.	1. The Parts of a Syllogism.	With reference to primary Notions	THE CATEGORIES.
		With reference to secondary Notions	ON INTERPRETATION.
	2. The Syllogism.	Generally	THE PRIOR ANALYTICS.
		Specially. Demonstrative	THE POSTERIOR ANALYTICS.
		Specially. Dialectic	THE TOPICS.
		Specially. Sophistic	ON SOPHISTIC ELENCHI.

With this tabular view the following general description of the contents of the Organon of Aristotle, by an able writer, will be intelligible. 'The incorrect notions which have prevailed and still continue to prevail in regard to the "nature and province of logic," are, without detraction from his merits, mainly to be attributed to the example and authority of the philosopher himself. The book of *Categories*, as containing an objective classification of real things, is metaphysical, not logical. The two books of *Posterior Analytics*, as solely conversant about demonstrative or necessary matter, transcend the limits of the formal science; and the same is true of the eight books of *Topics*, as wholly occupied with probable matter, its accidents and applications. Even the two books of the *Prior Analytics*, in which the pure syllogism is considered, are swelled with extralogical discussions. Such, for example, is the whole doctrine of modality of syllogisms, as founded on the distinction of pure, necessary, and contingent matter; the consideration of the real truth or falsehood of propositions, and the power so irrelevantly attributed to the syllogism of inferring a true conclusion from false premises; the distinction of the enthymeme through the extra formal character of its premises, as a reasoning from signs and probabilities; the physiognomic syllogism, &c. &c. The same is true of the book on *Interpretation* (περὶ Ἑρμηνείας); and matters are even worse with that on *Fallacies* (*Sophistic Elenchi*). If Aristotle therefore did more than any other philosopher for the progress of the science, he also did more than any other to overlay it with extraneous lumber, and to impede its development under a precise and elegant form. Many of his successors had the correctest views of the object and scope of logic; and even among the schoolmen there were minds who could have purified the science from its adventitious sediment, had they not been prevented from applying their principles to details by the implicit deference then exacted to the precept and practice of Aristotle.' (*Edinburgh Review*, April, 1833.)

It may indeed be strongly suspected that the various treatises which compose the Organon contain interpolations. Further, what we now have are only a part of the logical works of Aristotle; and even this part does not exhibit simply a logical system, properly so called, but rather a system of argumentative discourse.

We may remark of the Categories that attempts have been made to found a philosophical system upon them, as explained by Aristotle. They contain, as is observed by Dr. Whately, the explicit statement that though a primary substance signifies a particular thing, as 'a particular man,' 'a particular horse,' the general term 'man' or 'horse' (which he calls a secondary substance) only *appears* to denote a particular thing, but in fact does not; for the thing is not one, as in the case of a 'particular man,' but is said of many (v. 16, ed. Pac.). This is a clear statement that general terms do not indicate realities, but are only the expression of the mode in which the mind is affected.

In the Prior Analytics it has been stated that the pure syllogism is considered: the introductory chapter of the First Book states in a general way the objects of the science as conceived by Aristotle, and is expressed with his characteristic clearness.

'It is proper,' says Aristotle, 'first to state about what the inquiry is, and to what the inquiry belongs, namely, demonstration and demonstrative science. Then we must define Proposition (πρότασις), Term (ὅρος), and Syllogism (συλλογισμός); and what is a perfect and what an imperfect syllogism. Next, what is meant by one thing being or not being in the whole of another, and what we mean by a thing being predicated of all or none. A proposition then is a sentence (λόγος) which affirms or denies something of another thing; and this either universally, or particularly, or indefinitely. By universally, I mean where it applies to all or none; by particularly, where it applies to part or not a part, or not to all; and by indefinitely, where it applies, or does not apply, without anything being determined as to the whole or part. The demonstrative (*ἀποδεικτική*) proposition differs from the dialectic (*διαλεκτική*). The demonstrative is an assumption of one side of the question, namely, the contradiction; for he who demonstrates does not interrogate, but he assumes; but the dialectic is an interrogation as to the contradiction.[*] This however makes no difference with respect to the syllogism in either case, for both he who demonstrates and he who interrogates syllogise by assuming something to be predicated or not to be predicated of another thing. Consequently a syllogistic proposition will be simply an affirmation or denial of one thing with respect to another, in the way already mentioned; and a proposition will be demonstrative if it is true, and obtained by means of the original hypothesis. A dialectic proposition is, with respect to the question, an interrogation about denial; but to him who syllogises it is the assumption of that which is apparent and probable, as it is shown in the Topica. What then is a proposition, and in what respect a syllogistic, demonstrative, and dialectic proposition differ, will be accurately stated in what follows (in the 'Analytica Posteriora'); but for the present purpose what has been already said is sufficient.

'I call Term that into which a proposition is resolved, as the predicate (*τὸ κατηγορούμενον*), and that of which predication is made, with the addition or not of 'being,' or 'not being.' A syllogism is discourse, in which certain things being laid down, something different from these things necessarily results by virtue of these premises (*τῷ ταῦτα εἶναι*). And I mean by the words 'by virtue of the premises,' that this something results by reason of them (*διὰ ταῦτα*): and 'by reason of them' means that no other term is needed in order to this necessary result. Now, I call that a perfect syllogism which requires nothing else besides what is assumed or granted in order that the necessary conclusion may appear. I call that an imperfect syllogism which requires one or more things which are of necessity by virtue of the given terms, but are not assumed in the propositions. For one thing to be said to be in the whole of another, and one thing to be predicated of the whole of another, is the same thing; and I mean by predication of the whole of a thing, when one cannot conceive any part of the one thing (the subject) of which the other cannot be predicated; and the like when the predication is of no part of a thing.'

It was apparently the object of Aristotle in his so-called logical treatises, as we now have them, to make a perfect system of argumentative discourse, and not merely a logical (properly so called) system. It is probable that if all his works of this class were extant and arranged according to his own method, we should see still more clearly that the whole was not considered a logical system (as the term logic is strictly understood), but that a logical system (as the term is strictly understood) was contained in it. Whether Aristotle or any other person put the existing books of the Organon together, neither the author who conceived them in connexion with one another, nor any one else, considered them as forming a pure logical or even a pure dialectic treatise, but a treatise on argumentation. And this is clear enough from an examination of the contents of the Organon, and the remarks of Cicero (*Topica*) and his commentator Boethius, who was himself a writer on logic. Boethius, who uses the term *Logic*, informs us that the Peripatetics understood this term as Cicero understood it, and Cicero defines it to be 'disserendi diligens ratio,' or 'an exact method of argumentation.' The Peripatetics, he adds, understood logic to consist in invention and judgment; but the Stoics, who neglected invention, considered it to consist in judgment only, which they distinguished by the name of dialectic. Thus the logic of the Peripatetics was larger than the logic of the Stoics. The logic of the Peripatetics consisted, first of topic or invention, which teaches the method of easily discovering arguments; and Boethius remarks that Aristotle in his 'Topica' treats of the 'maximæ propositiones' (called *loci*), which are universal propositions, of undoubted truth, which need no demonstration, or probable propositions, and from which we descend to the conclusions of the syllogism. Judgment is more particularly exercised in making conclusions (in colligendi ratione), but inasmuch as all argumentation and syllogising depend on and are constructed of propositions, we have to consider both the matter of propositions and their connection. As to the *matter*, we have to consider whether the propositions are true, or necessary, or probable, or sophistical. As to the connection, we have to consider the union and the composition of the propositions, which may be called the *form* of the arguments. Logic then consists of invention, and of the conclusions from invention, or the form of the argumentation. The part which treats of invention supplies the instruments or means for invention, and, as already observed, is called Topice. The part which relates to judgment supplies certain rules for discerning or separating (discernendi), and is called Analytice: so far as it treats of the connection or union of propositions, it is called Analytice Prior; so far as it treats of the inventions themselves, it is called Analytice Posterior, when it is engaged about discerning necessary arguments; but when it is engaged about false and deceptive arguments (cavillatoria), that is, sophistical, it is called the Elenchi. Boethius then concludes that Aristotle treated of logic in a more complete manner than the Stoics, 'since he treated of the two things besides which there is no third, namely invention and judgment, while the Stoics neglected invention and only furnished us with the instruments of judgment.'

This statement of what the logic of Aristotle was, may help to remove certain long-rooted mistakes on the matter. Dr. Whately, who confines logic to the pure syllogism in his theoretical view of the subject, though not in his practical exposition of it, says that 'with the exception of Aristotle, hardly a writer on logic can be mentioned who has clearly perceived, and steadily kept in view throughout, its real nature and object.' And he remarks that even Aristotle is *not entirely* exempt from the error of mistaking the nature of logic and extending it to subjects with which it has no proper connection. Now the fact is that Aristotle's logic, being what we have here explained it to be, is a very different thing from what it appears to be considered to be by many. To say that Aristotle is *not entirely* exempt from the error above mentioned is rather a singular expression, when three-fourths of his Organon have nothing at all to do with the pure syllogism. In fact Aristotle's Organon, and his logic as explained by Boethius, are much more like Watts's much-abused 'Right Use of Reason' than like what many modern writers take them to be.

There is a short but not a satisfactory account of the contents of Aristotle's Organon by Dr. Thomas Reid, Edinburgh, 1806. It may however serve to give the reader some notion of the contents of the work. The best account of it is said to be by Barthélemy St. Hilaire, *La Logique d'Aristote*, 2 vols. 8vo.

The controversial tone of this article, in a work of this description, may require a word or two of apology. Until the limits of Logic are better defined, the subject must be controversial, for the question What is Logic? must continually recur. The work with reference to which these remarks are chiefly made has long had a great circulation, and has taken the place of former treatises, which is a sufficient reason why the errors of that work, if such they be, should be pointed out. In various parts of his work, Dr. Whately has explained with sufficient precision what he considers Logic to be: he has in fact defined it as the pure syllogism, irrespective of all material considerations. But in the execution of his plan he continually perplexes the reader with considerations as to the matter of propositions and terms; and he transcends the narrow limits within which the science, as he understands it, is confined. It cannot be supposed that a writer, however able, can so far deviate from a scientific method without serious prejudice to his work.[*]

Two reviews of Dr. Whately's treatise have fallen under our notice, one of which appeared in the 'Westminster

---

[*] *Τὴν διαλεκτικὴν ἐπιστήμην οὖσαν τοῦ ὀρθῶς διαλέγεσθαι περὶ τῶν ἐν ἐρωτήσει καὶ ἀποκρίσει λόγων.* (Diog. Laert., *Zeno*, vii., s. 84.)

[*] The edition of Dr. Whately's 'Logic' referred to in this article is the fourth. The writer did not know that there was a sixth, which contains some few alterations, till this article was ready for the press. The reader should refer both to the fourth and to the sixth editions.

Review,' for January, 1826; the other in the 'Edinburgh Review' for April, 1833. The former shows that Dr. Whately is not alone in some of those opinions which we consider erroneous. The latter is from a master-hand, who is well acquainted with both ancient and modern writers on logic and philosophy. To this article we are much and deeply indebted.

Several treatises on logic have appeared in Germany, which profess to exhibit the subject according to a strictly scientific method. Among these may be mentioned Kiesewetter's 'Grundriss einer Allgemeinen Logik nach Kantischen Grundsätzen,' 8vo., Berlin, 1791.

A complete catalogue of logical treatises would be very long; and the value of the catalogue would hardly compensate for its length. Writers have formed their notions of the science with more or less precision, but have seldom, perhaps, kept within their own limits; and this is a difficulty which is inherent in the subject. If confined to the bare affirmation or negation of propositions expressed by *is* or *is not* (considered simply as determinations of quantity), and to the pure syllogism, the theory of logic is soon exhausted, and as a science it is comprised within very narrow limits. If we once transcend those bounds, we enter into a wider sphere, in which the formal logic becomes a mere word. To ascertain the full import of the words *is* and *is not* in a proposition is the highest aim of philosophy.

ORIBA'SIUS (Ὀρειβάσιος, or Ὀριβάσιος), an eminent physician and the intimate friend of the emperor Julian, was born at Sardis, the capital of Lydia, according to Suidas and Philostorgius (*Hist. Eccles.*, vii. 15), or rather, according to Eunapius (*De Vitis Philosoph. et Sophist.*), who was his contemporary, at Pergamum, a celebrated city of Mysia, and the birthplace of Galen. After enjoying the advantage of a good education, he became a pupil of Zeno, an able physician of Cyprus, to whom the emperor Julian addressed a letter still extant (*Epist.* 45.). Oribasius soon became so famous in the practice of his profession as to induce Julian, upon being raised to the rank of Cæsar, to take him with him into Gaul as his physician, A.D. 355. Eunapius seems (in an ambiguous passage) to assert that it was partly by the assistance of Oribasius that Julian was declared emperor, and says that he has given the particulars of the transaction in another of his works, which is lost. But however this may be, it is certain that they were upon the most intimate terms, as is proved by one of Julian's letters addressed to Oribasius, which still remains (*Epist.* 17), and is at the same time a monument of their superstition and pagan idolatry. When Julian succeeded to the empire, on the death of Constantius, A.D. 361, he raised Oribasius to the rank of quæstor of Constantinople (Suidas), and afterwards sent him to consult the Oracle of Delphi, whence he brought back the celebrated answer, that the Oracles had ceased to utter predictions. (Cedrenus, *Chronic.*, p. 304, ed. Paris, 1647.) Oribasius accompanied the emperor in his expedition against Persia, and was present at his death. (Philostorg., *loc. cit.*) He afterwards fell into disgrace through the envy of his enemies, had all his estate confiscated, and was banished by Valentinian and Valens. He supported his misfortunes with fortitude, and by his medical talents gained so much love and reverence, that the *barbarians* (as they are called) began almost to adore him as a god. At last the emperors, feeling their loss of his professional skill, recalled him from banishment, restored his confiscated fortune, and loaded him with favours. He was still alive when Eunapius, who was his intimate friend, wrote his account of his life, which is placed by Lardner (*Heathen Testimonies, &c.*) about the year 400 (Dionys. Petavius, *Ration.*, lib. i., p. 437, ed. Paris, 1633, fol.), and as this was more than fifty years after his attending Julian in Gaul, he must have lived to a good old age. There are in the Greek Anthology two epigrams written in honour of him (lib. i., p. 65, and lib. iv., p. 405).

He was the author, according to Suidas and Photius, of several works which are no longer extant. A Commentary on the Aphorisms of Hippocrates goes under the name of Oribasius, but it is manifestly spurious. The author, who appears to have been a Christian, quotes the Holy Scriptures, and says in the preface that he wrote his work by order of Ptolemy Euergetes. It is of little value, and was first published at Paris, 1533, 8vo., ed. Jo. Guinterius Andernacus, Lat. The Greek text, if it exists at all, has never been published.

We possess three works bearing the name of Oribasius, which are generally considered to be genuine, viz.: 1, Συναγωγαὶ Ἰατρικαί, 'Collecta Medicinalia;' 2, Σύνοψις, 'Synopsis ad Eustathium;' 3, Εὐπόριστα, 'Euporista ad Eunapium' or 'De facile Parabilibus.' The first of these works was composed, as we learn from the preface or dedication preserved by Photius, at the command of Julian while they were in Gaul together, and consisted originally of seventy books, according to Photius (*Biblioth.*, cod. ccxvii.), or, as Suidas says, of seventy-two; whence it is also called Ἑβδομηκοντάβιβλος, 'Liber LXX.' Of this large work, which consisted almost entirely of extracts from Galen and other authors, we possess rather more than one-third part, namely, books 1-15, 24, 25, 43, 44, 45, 46, 47, 48, 49, and 50.* They are extremely valuable, both as containing passages from authors whose works are no longer extant, and also as serving frequently to correct and explain different sentences in Galen's works. It would be impossible here to give anything like a complete analysis of so large a work, and perhaps this is the less necessary as it contains but little original matter; but it may be useful to give a general idea of its contents, mentioning at the same time anything that may appear especially worthy of notice. The first five books treat of Diætetics; lib. vi. contains directions about sleep, exercise, friction, &c.; lib. vii. is on venesection, arteriotomy, cupping, purging, and emetics (he says that the effects of hellebore were first tried upon dogs and afterwards upon men, and that he cured by means of it a woman afflicted with cancer); lib. viii. is about clysters, with some more remarks on hellebore and emetics; lib. ix., on climate, winds, &c., and also on external applications; lib. x., on natural and artificial baths, containing a particular account of the oil baths and oil and water baths; the five following books are on Materia Medica; the twenty-fourth and twenty-fifth books contain a complete system of anatomy and physiology, taken almost entirely from Galen's great work, 'De Usu Partium Corporis Humani.' It should here however be noticed that Oribasius is the first author who gives an account of the salivary glands, which appear to have been overlooked by Galen; at least no description of them is to be found in any of his extant anatomical works. The passage in Oribasius occurs lib. xxiv., cap. 9, and is as follows: 'On each side of the tongue you will find the orifices of the vessels called salivary large enough to admit the end of a probe; they have their origin at the root of the tongue, where there are the glands of the same nature, for the vessels arise from them in the same way as arteries, by means of which the salivary moisture lubricates the tongue itself, and all the adjacent parts of the mouth.' The above seventeen books were for some time supposed to be all that remained of the Ἑβδομηκοντάβιβλος. They first appeared in Latin about 1550, Venet., s. a., 8vo., ed. J. Bapt. Rasarius, ap. P. Manutium, Aldi F. The first fifteen books were published, Mosquæ, 1808, 4to., Gr. and Lat., ed. Matthäi, under the title 'XXI. Veterum et Clarorum Medicorum Græcorum Varia Opuscula,' &c. Of the twenty-fourth and twenty-fifth books there is a good edition, Lugd. Bat., 1735, 4to., Gr. and Lat., ed. G. Dundass, with the title 'Oribasii Anatomica ex Libris Galeni,' &c. Cocchi however published, Florent., 1754, fol., Gr. and Lat., in his edition of the collection of surgical works by Nicetas [NICETAS], two works by Oribasius, περὶ καταγμάτων, 'De Fracturis,' and περὶ ἐξαρθρημάτων, 'De Luxatis,' which he conjectured to be the forty-sixth and forty-seventh books of the συναγωγή, and at the same time he expressed his opinion that the forty-third and forty-fifth books had long been before the public under the title 'De Laqueis et Machinamentis Chirurgicis ex Heraclide et Heliodoro,' contained in 'Vidi Vidii Chirurgia,' fol., Paris, 1544, and in the twelfth vol. of Chartier's edit. of Hippocr. and Galen. Angelo Mai has lately discovered in the Vatican library part of lib. xliv., 'De Abscessibus;' lib. xlv. 'De Variis Tumoribus;' lib. xlviii. 'De Laqueis;' lib. xlix. 'De Machinamentis;' and part of lib. l., 'De Pudendorum Morbis.' These he has published in the fourth vol. of 'Class. Auctor. e Vatic. Codic. Edit.,' 8vo., Romæ, 1831. The contents of the last-mentioned books are sufficiently expressed by their titles, nor is there anything in them deserving of particular notice.

The second of the extant works of Oribasius (called σύνοψις, 'Synopsis,' and addressed to his son Eustathius) consists of nine books, which, as we learn from the preface, was composed after the former work, and is an abridgement of it. In the first book he treats of various kinds of exercise, baths, external applications, cupping, scarification, leaching, &c.; he also gives directions for choosing which vein in the arm to open in phlebotomy, and says that it is dangerous to touch the *median*, on account of the proximity of the nerve; that arteriotomy should be performed on the temples or behind the ears. He next gives (lib. ii.) a list of simple drugs with their properties; lib. iii. treats of plasters and other external medicaments; lib. iv., of materia medica; lib. v., of diseases of women and children, &c.; lib. vi., of fevers, contagion, &c.; lib. vii., of surgery; lib viii., diseases of the head, eyes, and ears, lycanthropia, and hydrophobia; lib. ix., diseases of the thorax, abdomen, kidneys, &c.; also on diabetes, in which disorder he recommends sudorifica. The Greek text of this work has never been published; a Latin translation by J. Bapt. Rasarius appeared, Venet., 1554, 8vo., ap. P. Manutium.

---

* F. R. Dietz states in the preface to his 'Scholia in Hippocr. et Galen.' 8vo. (Regim. Pruss., 8vo., 1834, 2 vols.), that he discovered the same books that had been mentioned by Mai, but does not specify which they are. These he intended to insert in their proper places in the new edition of Oribasius which he was preparing for the press at the time of his death.

The third extant work by Oribasius bears the title of εὐπόριστα, 'De facile Parabilibus,' and is addressed to his friend Eunapius (though some copies in the time of Photius read *Eugenius*), at whose desire it was composed, and who is probably the author of the 'Vitæ Philosoph. et Sophist.' It consists of four books, which seem to be a short abridgement of his great work, chiefly taken from Galen, Dioscorides, and Rufus Ephesius. It genuineness is boubted by Sprengel. Of this work also the Greek text has never been published. A Latin translation by J. Sichard came out, Basil, 1529, fol., and another by J. Bapt. Rasarius, Venet., 1558, 8vo. Rasarius also published, Basil, 1557, 3 tom. 8vo., an edition of his translations of all the works of Oribasius, which are inserted in the first volume of the 'Medicæ Artis Principes,' by H. Stephens, Paris, 1567, 2 tom. fol.

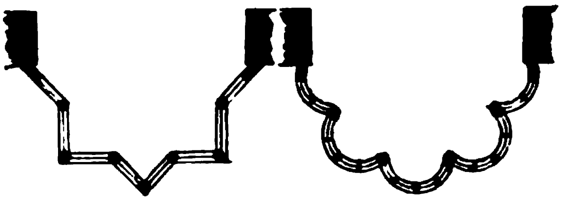
Oribasius has been called 'Galen's ape,' and it is true that he seldom contradicts him; but he has also inserted in his works so much that is original, that it is surprising that he should have confined himself to the office of a mere compiler.

ORICHALCUM, or AURICHALCUM, one of the antient names for brass. [BRASS.]

O'RICOU. [VULTURIDÆ.]

ORIEL. The origin of this term is very obscure, and has hitherto baffled all etymologists. Some have supposed it to be derived from *Oriens*, as if windows of this description were first introduced in an eastern aspect; of which there is no proof, nor indeed any probability. Others again have derived it from *orare*, through the low Latin word *oratoriolum*, signifying a small oratory or prayer-closet, to which use such bays within chambers may have been occasionally applied. The term Oriel however is thoroughly established, and the meaning now affixed to it is sufficiently clear and precise. It is applied to that particular kind of bay-window which is made to project from the upper story of a building. The distinction therefore between a bay and an oriel is this: by the former is understood a projecting window, or rather a projection pierced with window openings in its entire width, and rising immediately from the ground, whether it be confined to the lower part of the building or carried up through one or more stories above the ground-floor; by the latter, a bay which does not descend to the ground, but is suspended over the face of the wall beneath it. Oriel accordingly corresponds with the German terms *Erker-fenster* and *Chor-fenster*, which are almost the only ones of similar import in any foreign language. This absence of a name for it is accounted for by the thing itself being scarcely known in the architecture of other countries, and in our own it occurs only in our Domestic Gothic or Tudor, such form of window being very rare indeed in ecclesiastical structures. In our domestic, which also comprises collegiate architecture, it is a beautiful and valuable feature, and one which admits of very great diversity of design, and also imparts much variety and liveliness of effect to a building, more especially if there be ground-bays likewise, the two kinds of projection both harmonising and contrasting with each other.

Internally there is no distinction between Bays and Oriels, inasmuch as both the one and the other form a recess whose filled with windows. But greater variety of plan riels than in bays, which are usually more spacious dth and of shallower proportions as to depth; lso either rectangular in plan, or form three sides of an octagon, whether a regular one or not; whereas curved forms are of frequent occurrence in the plans of oriels, and are occasionally combined with straight ones. Yet as similar plans do occur in bays, no real distinction can be founded upon such accidents of design. Thornbury Castle, Gloucestershire, contains an example of a bay of very unusual character, both in respect to plan and elevation, its plan in the upper part being different from that of the lower, and in some degree projecting over it, as is indicated in the annexed figures, the first of which describes the plan of the lower, the other of the upper floor.



Though these figures will suffice to give some general notion of the forms, for a complete illustration of this singular specimen we must refer to the 'Second Series of Pugin's Gothic Examples;' merely adding here, that, considered singly, the plans have a picturesque complexity, and that such quality is greatly enhanced by their being combined.

Bays generally terminate in either a plain or embattled parapet; but oriels are for the most part made to show some sort of roof, either rising behind or resting upon the mouldings which serve as their cornice. Occasionally this roof or *crown* is rendered an ornamental part of the design, and terminated by some kind of finish. Oriels may therefore be described as consisting of three distinct parts, viz. the supporting portion, consisting of a series of mouldings, splayed off so as to come down to a point below, somewhat after the manner of a corbel (for which member we would accordingly suggest *corbel-stool* or *corbel-base* as a significant and very convenient term); 2ndly, the body of the oriel, consisting of the *window-apron* or window-parapet, and the window-openings themselves, the former of which is almost invariably panelled so as to correspond with the lights themselves, whereby the whole is made to consist of a series of panels, those in the lower range being blank or solid, the others perforated and glazed; 3rdly, the *crown* or roofing, occasionally including under that term the ornamental finish, of whatever kind it may be, above the windows, when that happens to form a conspicuous termination to the design, as is the case with the semicircular oriel at Great Chalfield, where the parapet is formed by a rich bandeau or crown of strawberry-leaf ornaments or *Tudor-flowers* with open work between them. (For drawings of this beautiful example and all its details, see Walker's *Manor-House at Great Chalfield.*)

The *corbel-stool* admits of very great variety and freedom of treatment, it being sometimes formed of few and bold mouldings and surfaces, at others of numerous and delicate ones. Neither does it invariably approach to a point at its termination, but finishes horizontally, and in some instances in a line as wide as the central division of the window. In fact there is such great diversity of design in respect both to the general form and design of the corbel-stool, that it is impossible here to enumerate all the varieties. In some oriels this part is made to assume the form either of a single or double pendant; in others the mouldings are in somewhat a similar fashion, being made to slope downwards instead of being carried horizontally. These pendant-like supports sometimes rest upon or seem to spring from armorial shields, carved heads, or other ornamental devices: neither are instances wanting of the corbelling resting upon a column or some kind of shaft, for which member the suitable denomination would be *corbel-shaft* or *corbel-stem*. In some later examples, again, of the Elizabethan period, instead of being supported beneath by corbellings, the window rests upon large trusses or brackets; windows of this description however partake very little of the character of oriels, and can hardly be described as being of the same class. Some distinctive term therefore for windows of that sort would be useful, as would likewise some others, in order to express various particulars which, for want of them, cannot be pointed out without more or less of circumlocution. The term *jutting-window* might be adopted for that species of upper window, which, although situated like the oriel, merely juts out from the surface of the wall, and forms scarcely any recess within the room. On the other hand, where a window, either bay or oriel, forms an unusually deep recess or distinct alcove to an apartment, having its ceiling detached from that room instead of being in continuation of it, such window might, as regards the interior, be very well described as a *bower*-window, which term would at once describe the difference between it and the ordinary bay; the example of the two oriels at Great Chalfield, which has been above referred to, perfectly answers to this term, as they form an alcove nearly as deep as wide, have an enriched vaulted ceiling, and are set within an arch whose mouldings serve as a frame to the whole recess.

Although no such work has hitherto been attempted, a monograph on bays and oriels might be rendered one of great interest. The materials for it are abundant, and many fine examples might be collected from various colleges at Oxford, as Balliol, Lincoln, Magdalen, All Souls, St. John's, &c.

Nurnberg also furnishes some interesting specimens of such windows, several of which are to be found in Heideloff's 'Nürnbergs Baudenkmale der Vorzeit,' including that at the Pfarrhof of St. Sebald, so greatly extolled by Dr. Dibdin on account of its bas-relief pannels.

ORIEL COLLEGE, OXFORD, was founded by king Edward II. in 1326, on the suggestion of Adam de Brome, his almoner, for a provost and ten fellows. The number of fellows has been since increased by various benefactions. Four, for the counties of Somerset, Dorset, Wilts, and Devon, were added by John Frank, master of the rolls, who died A.D. 1441; one for the old diocese of Worcester, by John Carpenter, bishop of Worcester, about the year 1476; one for the old diocese of Lincoln, by William Smyth, bishop of Lincoln, 1507; and two by Richard Dudley, chancellor of the church of Salisbury, 1529. Queen Anne, in 1713, annexed a prebend of Rochester to the provostship for ever. Several exhibitions and scholarships have been founded in this college by different benefactors, namely, three (for bachelors of arts) by Dr. Robinson, bishop of London, 1718; six by Richard Dudley, above mentioned, and Mr. St. Anthony; four under the will of Henry, duke of Beaufort, 1744; two under that of Mrs. Ludwell, 1761; and two were established by the Society, 1800. The foundation now consists of a provost and eighteen fellows, with seventeen scholars and exhibitioners.

This college took the name of Oriel from a large messuage, situated partly in the parish of St. John Baptist, in Oxford, and partly in St. Mary's parish, called La Oriole, which was granted to the provost and fellows, in 1327, by king Edward III., to which they removed at that time from the tenement in St. Mary's parish, where they had been first established. The hospital of St. Bartholomew, near Oxford, with all its appurtenances, was also granted to the college by king Edward III., at Adam de Brome's request, chiefly as a place of retirement for the Society in times of plague.

Among the eminent persons educated at this college were:—Archbishop Arundel; Reynold Pecock, bishop of Chichester in the time of Henry VI.; Bishop Butler, author of the 'Analogy;' Barclay, the translator of Brandt's 'Ship of Fooles;' Cardinal Allen; Sir Walter Raleigh; Prynne; Chief Justice Holt; and Dr. Joseph Warton.

No part of the present buildings of this college is of an earlier date than 1620, when the southern and western sides of the antient quadrangle were rebuilt. The hall and chapel, which are on the eastern side of the quadrangle, were rebuilt between 1637 and 1642. About or soon after this time, the north side was reconstructed, and made uniform with the other three sides. The hall is ascended by steps, under a semi-hexagonal porch, above which, in niches in the outer building, are statues of Edward II., Edward III., and the Virgin and Child.

Beyond this quadrangle, on the east and west sides of the garden, are two handsome buildings; that on the east was built in 1719, at the expense of Dr. Robinson, bishop of London before mentioned; that on the west, called Carter's Building, was constructed in 1729, in pursuance of the will of George Carter, D.D., for some time provost, who bequeathed his whole property to this college, partly for this purpose, and partly to purchase advowsons. In 1817 fifteen additional sets of rooms were built on the south side of Bishop Robinson's wing.

Between Carter's and Robinson's Buildings stands the library, begun in 1788, from a design by Mr. James Wyatt, one of the most chaste buildings of its kind in Oxford.

The patronage of Oriel College consists in the rectories of Ufton Nervet in Berks, Plymptree in Devon, Purleigh in Essex, and of Cromhall and Tortworth in Gloucestershire; the vicarage of Coleby and the rectory of St. Peter's Saltfleetby, in Lincolnshire; the curacy of Morton Pinckney, in Northamptonshire; the vicarage of St. Mary the Virgin, in Oxford; the curacy of Swaynswicke and the vicarage of Twiverton, in Somersetshire; the rectory of Chaldrington, alias Chelderton, in Wilts; and the vicarage of Aberford, in Yorkshire.

The number of members upon the college books, Dec. 31, 1838, was 327.

(Chalmers's *Colleges and Halls of Oxford*, vol. i., pp. 77-97; Ingram's *Memorials of Oxford*; *Oxford Univ. Calendar*, 1839, pp. 230-235.)

ORIFLAMME. [BANNER.]

ORI'GENES (Ὠριγένης), commonly called by English writers Origen, was born in Egypt in the year 184 or 185 A.D. Porphyry states that he was born of heathen parents and brought up in the Greek religion, but this is denied by Eusebius. He received instruction from Clemens of Alexandria, then a catechist at Alexandria, and at a later period he attended the lectures of the celebrated philosopher Ammonius Saccas. In the year 202 his father Leonides suffered martyrdom. Though not quite seventeen years old, Origen was hardly restrained by the care of his mother from offering himself also to martyrdom. He sent a letter to his father in prison, containing this sentence:—'Take heed, father, that you do not change your mind for our sake.' After his father's death, Origen was supported for a short time by a rich lady of Alexandria, but he soon became able to maintain himself by teaching grammar. At the age of eighteen, Demetrius the bishop of Alexandria put him at the head of the catechetical school in that city, to the duties of which office he devoted himself entirely and with great success. During this period he supported himself by the sale of his library of antient authors for a daily stipend of four oboles, which he received from the purchaser. We are not told how long this payment was continued. In his twenty-first year, having taken up the opinion that the words of our Saviour (*Matthew*, xix. 12) ought to be understood literally, he castrated himself; in later life he confessed his error in this matter. Soon after this he learned Hebrew, a thing very unusual at that time (Hieron., *De Vir. Illust.*, c. 56); but his knowledge of the language was never very great. About the year 212 his preaching reclaimed from the Valentinian heresy a wealthy person of the name of Ambrose, who afterwards assisted him materially in the publication of his Commentaries on the Scriptures. He was sent by Demetrius into Greece upon some ecclesiastical business, and on his way thither, in 228, he was ordained a presbyter at Cæsarea in Palestine. This circumstance excited the jealousy of Demetrius to such a degree, that when Origen returned home he found that prelate violently opposed to him; he therefore left Alexandria and retired to Cæsarea in 231. Demetrius held two councils at Alexandria upon this occasion, by the first of which Origen was forbidden to teach or even to appear in the city; by the second, he was deposed from the office of presbyter, and perhaps excommunicated. Demetrius moreover sent letters to most of the churches, in consequence of which Origen was condemned by the bishop of Rome, and by all others except those of Palestine, Arabia, Phœnicia, and Achaia. Jerome states that these proceedings were not taken because Origen was guilty of any heresy, but solely from jealousy of his eloquence and reputation. While Origen resided at Cæsarea, he was resorted to by persons from the most distant places, who were anxious to hear his interpretations of the Scripture. Among his disciples were several who afterwards rose to great eminence in the church. His advice was now eagerly sought for. Mammæa, the mother of the emperor Alexander Severus, sent for him to Antioch that she might converse with him on religion; and at a later period he had a correspondence with the emperor Philip and his wife Severa. At two synods which were held about this time in Arabia he again enjoyed the success, rare indeed in religious controversy, of convincing his opponents: these were, Beryllus, bishop of Bostra in Arabia, who denied the pre-existence of Christ, and some who held the opinion that the human soul dies with the body, and will be revived with it again at the resurrection. He also paid visits to the churches of Rome and Athens; the former of these visits was some time before he left Alexandria, and the object of it was, as he himself tells us, 'to see the most antient church of the Romans.' When he was sixty years old he permitted his discourses to be taken down in short-hand, and in this way above a thousand of his homilies were preserved.

It was about this time that he wrote an answer, in eight books, to the objections brought against Christianity by Celsus, a philosopher who lived in the reigns of Hadrian and the Antonines, in a work entitled 'The True Word' (Λόγος 'Αλήθης). The objections of Celsus, as they appear from the answer of Origen (for the work itself is lost), are of a frivolous and malignant character, and the work of Origen has been esteemed both in ancient and modern times, not only as a satisfactory answer to his opponent, but as one of the best apologies for the Christian religion that have been written by the antients.

In the Decian persecution (A.D. 250) Origen was imprisoned and suffered great tortures. He died shortly after his release from prison, some say at Tyre, in A.D. 253, in the sixty-ninth or seventieth year of his age.

Origen is undoubtedly one of the most remarkable men among the antient Christian writers. His talents, eloquence, and learning have been celebrated not only by Christian writers, but by heathen philosophers, including Porphyry himself. Jerome calls him 'a man of immortal genius, who understood logic, geometry, arithmetic, music, grammar, rhetoric, and all the sects of the philosophers; so that he was resorted to by many students of secular literature, whom he received chiefly that he might embrace the opportunity of instructing them in the faith of Christ.' (*De Vir. Illust.*, c. 54.) Elsewhere he calls him the greatest teacher since the apostles. We find this same Jerome however at a later period of his life violently attacking Origen and approving of the persecution of his followers. Sulpicius Severus says that in reading Origen's works he saw many things that pleased him, but many in which he (Origen) was undoubtedly mistaken; he wonders how one and the same man could be so different from himself; and adds, 'where he is right, he has not an equal since the apostles; where he is in the wrong, no man has erred more shamefully.' (*Dialog.*, i. 3.) All agree that he was a man of an active and powerful mind and of fervent piety, fond of investigating truth, and free from all mean prejudices, of the most profound learning and of the most untiring industry. His whole life was occupied in writing, teaching, and especially in explaining the scriptures. No man, certainly none in antient times, did more to settle the true text of the sacred writings and to spread them among the people, and perhaps few have introduced more dangerous principles into their interpretation. For, whether from a defect in judgment or from a fault in his education, he applied to the holy scriptures the allegorical method which the Platonists used in interpreting the heathen mythology. He says himself that 'the source of many evils lies in adhering to the carnal or external part of scripture. Those who do so shall not attain to the kingdom of God. Let us therefore seek after the spirit and the substantial fruit of the word, which are hidden and mysterious.' And again, 'the scriptures are of little use to those who understand them as they are written.'

In the fourth century the writings of Origen led to violent controversies in the church. Epiphanius, in a letter preserved by Jerome, enumerates eight erroneous opinions as contained in his works. He is charged with holding heretical notions concerning the Son and the Holy Spirit; with maintaining that the human soul is not created with the body, but has a previous existence; that in the resurrection the body will not have the same members as before; and that future punishments will not be eternal, but that both fallen angels and wicked men will be restored at some distant period to the favour of God. (Hieron., *Adv. Ruf.*, lib. ii., tom. iv., p. 403.) These opinions were not generally held by his followers, who maintained that the passages from which they were drawn had been interpolated in his writings by heretics. In 401, Theophilus, bishop of Alexandria, held a synod, in which Origen and his followers were condemned, and the reading of his works was prohibited; and the monks, st of whom were Origenists, were driven out of Alex- ia. His opinions were again condemned by the second al council of Constantinople, in A.D. 553.

The most important works of Origen were his editions of the Hebrew text and Greek versions of the Old Testament, which were the results of a diligent collation of manuscripts. The 'Tetrapla' contained the four Greek versions of Aquila, Symmachus, the Septuagint, and Theodotion, arranged in four columns. The addition of the Hebrew text in one column, and of the same in Greek characters in another, formed the 'Hexapla.' Of this great work only a few fragments remain, the best edition of which is that by Montfaucon, in 2 vols. fol., Paris, 1713. Of his other works, which were so numerous that one author states that he wrote six thousand volumes, the greater number have perished. His 'Stromata' and 'Principia' (περὶ ἀρχῶν) illustrated the doctrines of Christianity according to his peculiar method of interpretation. The 'Stromata' was in ten parts, and illustrated the doctrines of Christianity by comparing them with the opinions of the philosophers. Three fragments of this work are preserved by Jerome. The 'Principia' was in four books, but we only possess a short notice of it in the 'Myrioblon' of Photius (cod. viii.), an extract in Eusebius (*Contra Marcellum Ancyranum*, lib. i., one or two in Justinian's *Letter to Mela*, and some fragments in the 'Philocalia.' Rufinus, in the fourth century, made a Latin translation of the 'Principia,' which is still extant; but Rufinus has, by his own confession, added so much to Origen's work, that it cannot be taken as a fair exhibition of his opinions. Indeed all the extant works of Origen are very much corrupted.

We have still in Greek his treatise 'Of Prayer,' his 'Exhortation to Martyrdom,' his 'Apology for the Christian Religion,' an Epistle to Africanus, another to Gregory Thaumaturgus, and fragments of a few other epistles; part of his 'Commentaries on the Books of the Old and New Testament;' 'Philocalia,' containing extracts from his works made by Gregory of Nazianzus and Basil the Great; and in the 'Catenæ' there are many notes ascribed to Origen, which Huet however considers to be spurious. Several of his works remain in Latin translations, made by Jerome and Rufinus, but chiefly by the latter. Complete lists of his extant works are given by Huet, Cave, Basnage, Du Pin, and Tillemont, and by Fabricius in the *Bibl. Græc.*, v. i., 26. The standard edition of his whole works is that of De la Rue, in 4 vols. fol., Paris, 1733.

(Huet, *Origeniana*; Lardner's *Credibility*, part ii., chap. 38, and the authorities quoted by him; Mosheim's *Ecclesiastical History*.)

ORI'GENES, also a pupil of Ammonius Saccas, must be distinguished from the other Origen. Longinus and Porphyry mention three of his works, entitled, 'On Dæmons,' the 'Demiurgus,' and 'Galienus.'

ORIHUELA, a city of Spain, and the chief town of the district of Orihuela, in the kingdom of Valencia. It is situated in 38° 8′ N. lat. and 1° W. long., and lies on the banks of the Segura, in an extensive plain at the foot of a lofty mountain of limestone, which overhangs it precipitously on the north. This plain, or *huerta*, as it is called, is about 17 miles from east to west, and about 5 miles in average breadth from north to south. It is bounded on the north and south by ranges of hills and mountains bare of trees, on the east by the Mediterranean, and on the west by the huerta of Murcia, of which it is a prolongation. The soil is a rich clay, with a mixture of sand in some parts, resting on a stratum impervious to water. On the eastern side are many strips of sand, which the Segura has deposited in its overflowings, but these are of small moment in comparison with the exceeding fertility of the rest of the huerta, which is esteemed the richest and most beautiful in Spain. 'The orange-trees of the huerta,' says Miñano, 'besides their utility, embellish the scenery and give balminess to the air; ever charming by the brilliant green of their foliage, by the multitude and fragrance of their flowers, and by the beauty of their fruit, they form delightful orchards, alternating with groves of mulberries and other fruit-trees. Delicious is it to repose beneath these shades, where the taste, the eye, and the smell receive impressions equally grateful. The murmuring of the waters which flow through the trenches, the variety of fruits, the gaiety of the peasantry, and the purity of the sky, give rise to elevated ideas, so that some foreigners have fancied they here found the delicious spots depicted by Milton in his "Paradise Lost."' Fig and pomegranate trees, silver elms, and cypresses diversify the vegetation of the huerta, while clumps of date-palms towering above all impart an oriental character to the country. The huerta yields also abundance of hemp, flax, wheat, barley, canary-seed, lucerne, maize, and vegetables; with wine, oil, silk, and barilla, and affords pasturage to cattle of all sorts. It is deservedly called 'the Garden of Spain,' a distinction due to its delightful and salubrious climate, the industry of its inhabitants, and the abundance of water which is conveyed to every part of it by means of artificial canals, making it independent of the sky for its supply of moisture, and giving rise to the proverb—

Llueva o no llueva,
Trigo en Orihuela.
(Rain or no rain,
In Orihuela there is grain.)

The population of the huerta, which contains twenty-nine towns and villages, amounts, according to Antillon, to nearly 50,000, of whom about 23,550 belong to the city of Orihuela. The city is four leagues distant from Murcia, ten from the Mediterranean, nine from Alicante, the same from Cartagena, and thirty from Valencia. It is the see of a bishop, and its chapter comprises five dignitaries, seventeen canons, twelve prebendaries, and twelve semi-prebendaries: it has also a collegiate chapter at Alicante. Besides its cathedral, Orihuela has three parish churches, two more without the walls, and five dependent churches; nine convents of monks and three of nuns (suppressed in 1835), two hospitals, a foundling hospital, a house of refuge, a theatre, a public granary, a cavalry barrack, a post-office, and seven inns. Its institutions for public instruction are a university, connected with that of Valencia, a seminary, and two colleges, in all which education is much neglected.

The city is divided by the Segura into two parts, which communicate by two bridges. It is also divided into four wards. In form it is long and narrow, winding round the base of the mountain La Muela, which overhangs it. The streets are straight and broad, but unpaved. The public buildings are not worthy of notice, but the private houses are for the most part regular and tolerably handsome; and the general aspect of the city is cheerful and agreeable.

The inhabitants of Orihuela are noted for their superstition and demoralization; and also for their industry. Though they are for the most part agriculturists, the city has a thriving commerce, and manufactories of linens, hats, soap, and starch, some tanneries, eleven flour-mills, and more than 150 oil-mills. Its annual contribution to the exchequer is only 2790*l.*

Orihuela is one of the most ancient cities of Spain, having existed before the time of the Carthaginians. It passed from their hands into those of the Romans, Goths, and Moors successively; and in A.D. 1037 was made the capital of one of the petty kingdoms into which the khalifate of Cordova was divided. It was soon re-annexed to the kingdom of Cordova, and in 1079 was included in the kingdom of Murcia, then established by Aben Hud. It fell into the hands of the Christians in 1265, when it was taken by James I. of Aragon.

(Minano; Antillon; Laborde, *Itin. Descrip. de l'Espagne*; Townsend's *Journey through Spain*; Inglis, *Spain in 1830*; Minano, *Dicc. Geo. de España*.)

ORILLON. [Bastion.]

ORINOCO, a large river of South America, which has its origin, according to the most recent information, not in the west, but on the southern declivity of the eastern part of the mountain system called Parime, but its source has never been visited by Europeans, nor has any information respecting it been obtained from the natives. It is supposed that this river rises near 64° W. long., and between 3° and 4° N. lat. Humboldt advanced up the stream as far as the mission of Esmeraldas, and he says that some monks had penetrated several miles farther to the confluence of the river Chiguire, where the Orinoco is so narrow that the natives have made a bridge over it of creepers at the foot of a cataract. Above this fall the country is in possession of the Guaicas, a race of aborigines of rather white complexion, who prevent foreigners from advancing farther into the mountain region. Schomburgk confirms this account.

At this point the river runs in a general western direction, and several miles farther down it divides into two arms, of which that which flows to the southwest is called Casiquiare, and after a rapid course of nearly one hundred miles joins the Guainia, or Rio Negro, thus forming a natural water-communication between the Orinoco and Amazon, into which latter river the Guainia falls. [Brazil, p. 360.] The Orinoco continues a wide river, running in a western direction along the southern base of the Parime mountains, until it approaches 68° W. long., where it is joined by the Atabapo from the south and by the Guaviare from the west. From the confluence of the last-mentioned river its course lies to the north, along the western base of the Parime Mountains, and in this part its navigability is interrupted by the Raudales of Maypures and Atures, between 5° and 5° 40′ N. lat. The Raudales are a peculiar kind of cataract. The great volume of water does not descend at once from a considerable height, as in the Niagara river, nor does it traverse a narrow opening between rocks, like the Amazon in the Pongo de Manseriche, but the bed of the Orinoco at Maypures and Atures, which is nearly 8000 feet wide, is divided into numerous narrow channels by rocks and rocky islands, between which the water runs with great rapidity, and forms a succession of small cascades. The highest of these cascades does not exceed nine feet, and the river descends in about six miles only about thirty feet by all the cascades of the Raudale of Maypures. But the velocity with which the confined body of water runs in the narrow channels renders it impossible to ascend the raudale. The Raudale of Atures is only half a mile long, and of a similar description. Below these raudales the river continues to flow between low but rocky banks. Opposite the mouth of the river Meta, which joins it from the west, is a powerful whirlpool round an isolated rock, called the Stone of Patience, from the circumstance of its generally taking two days to pass it at low water.

Some distance farther down the whole bed of the river is narrowed by rocks, which advance into it from both sides, and the stream flows rapidly through the Narrow of Baraguan, which is 1893 yards wide. But before it reaches the mouth of the Apure river it leaves the rocky country, and no other impediment to navigation occurs, except the Boca del Infierno, near Muitaco, a whirlpool produced by a ledge of rock, which however does not cross the whole bed of the river, nor prevent vessels of three hundred tons burthen from ascending as far as the mouth of the Apure. From the junction of the Apure the course of the Orinoco lies eastwards to the point where it empties itself into the Atlantic Ocean. In this part of its course the navigation for boats is rendered dangerous by the floating rafts, which consist of forest-trees torn from their natural seat by the inundations of the river, and covered with aquatic plants. Near the town of Angostura the river again runs between rocks for a short distance, but though in one place it is not more than 710 yards wide, this narrow (Angostura) may be passed without danger. Below Angostura vessels of considerable burthen may ascend the river with the trade-wind, which blows constantly from November to May, but it is necessary to avoid the numerous sand-banks, which are dangerous when the water is low, especially after the month of January. These sand-banks are also subject to changes.

Several islands occur in the Orinoco below Angostura. They are generally of moderate size, partly low and partly rocky. The rocky islands belong to the Parime Mountains, along the northern base of which the river flows in the lower part of its course. About 130 miles from its mouth the delta of the Orinoco begins. The river sends off to the north a branch, which soon divides into a great number of other branches, all known by the general name of Bocas Chicas (small mouths). They are all narrow when compared with the principal branch of the river, called Boca de Navios, but most of them are deep enough to admit vessels of considerable size. Of late these branches have been much frequented by smugglers, but they can only be navigated under the guidance of the Indians who inhabit the islands of the delta, and who are well acquainted with the numerous channels which the river has formed in the soft alluvial soil of the delta. The Bocas Chicas empty themselves partly into the Atlantic and partly into the Gulf of Paria, between the continent of South America and the island of Trinidad. Ten of them are rather large rivers: their names, enumerating them from east to west, are Caño de Lauran, Caño de Nuina, Caño Chico de Mariusas, Caño Grande de Mariusas (navigable), Caño de Macareo (navigable), Caño de Cucuina (narrow, but deep), Caño de Pedernales (navigable), Caño de Manamo Chico, and Caño de Manamo Grande. The three last mentioned fall into the Gulf of Paria. The Boca de Navios, or principal branch of the Orinoco, runs eastward to the ocean, and is divided for a distance of about forty miles into two channels by a series of islands which lie nearly in the middle of the stream. These channels are known by the Indian names of Zacupana and Imataca, and their eastern extremity is not quite thirty miles from Cape Barima, which is situated at the mouth of the river. Both are navigable, but that on the south, called the Channel of Imataca, though wider has less water; it is however commonly used by large vessels. Each of these two channels is more than two miles wide, and the whole width of the river, including the islands, considerably exceeds five miles. From this point farther down, the breadth continues to increase, and at the mouth, between Punta Barima on the south and the island of Cangrejos on the north, it is more than sixty miles wide. The navigable channel, which lies in the middle, is crossed by a sand-bar with seventeen feet of water, and in breadth varying from two miles and a half to three miles or a little more. Within the bar the water deepens on the side of the island of Congrejos to four and five fathoms, and the navigable channel is more than twelve miles wide. Though no arms branch off from the Boca de Navios to the south, the low country which extends from the Punta Barima to the mouth of the Essequibo river, and is watered by several small streams, is traversed by narrow natural canals called *etabbos*, which generally lie parallel to the shores of the Atlantic, and connecting the small streams, constitute an internal water-communication for small boats between the Orinoco and Pomeroon rivers.

The tributaries of the Orinoco are very numerous, and many of them have both a long course and a great volume of water. Those which join it on the left are navigable through nearly the whole of their course, and are rarely impeded by rapids; some of them are already navigated. But the rivers which fall into it on the right, originating on the elevated region of the Parime Mountains, descend from them by numerous rapids and cataracts, so as to be, at least for a great part of their course, entirely unfit for navigation. We shall only mention a few of them.

The Guaviare rises near 3° N. lat., in the declivities of the Paramo de Summa Paz, a portion of the great chain of the Andes, but the upper part of its course is not known. According to information collected from the native tribes which inhabit the adjacent country, this river, like the Orinoco, divides into two branches, of which one running south-east joins the Uapes, an upper branch of the Guainia, or Rio Negro, so as to constitute another natural water-communication between the two water systems of the Orinoco and Amazon. This branch is said to have been once navigated by a Portuguese, Cabuquena, and is accordingly called the Channel of Cabuquena. The lower course of the Guaviare does not seem to oppose any obstacles to navigation, but as no European settlements have yet been established on the banks, it is only navigated by the native tribes. It falls into the Orinoco near 4° N. lat., after a course of more than 500 miles.

The Rio Meta, which joins the Orinoco near 6° N. lat., originates with its numerous branches in the Andes east of Bogota, the capital of New Granada, and is said to be navigable for about 100 miles from that town, but it is not used. The most northern of its affluents however, the Rio Casanare, is navigated, as it originates not far from one of the most frequented mountain-passes of the Andes, that of Toxillo, which leads to the valley of the Rio Sogamozzo, north of Bogota. English manufactured goods, sent from Trinidad, are carried up the Orinoco, Meta, and Casanare, and over the mountain-pass to Bogota and the adjacent tracts. The course of the Rio Meta exceeds 500 miles, and that of the Casanare perhaps 300 miles.

The Rio Apure, which joins the Orinoco between 7° and 8° N. lat., likewise from the left, enters it by a great number of channels, and brings to it the waters of innumerable large streams, which partly originate on the eastern declivity of the Andes north of 6° N. lat., and partly descend from the southern slope of the maritime mountains of Caracas. This river receives all the waters which descend from a mountain-range more than 600 miles in length. The Apure itself rises in the Sierra de Merida, and runs more than 100 miles along its base to the south-west, and afterwards from west to east, collecting in its course all the waters which descend from the Andes. Before it joins the Orinoco, after a course of about 450 miles, it enters an extremely low and level country of considerable extent, which for several months of the year is changed into porary lake. Through this alluvial country it has cut er of channels, by which it discharges its own waters se brought down by other rivers from the maritime mountains of Caracas. Almost all the rivers descending from the last-mentioned range unite at one place, a little above St. Jayme, and form a large body of water, which, about thirty miles lower down, falls into the Apure, about fifty miles from its mouth. All these rivers are navigable through nearly the whole of their course, but are not navigated, as they drain the Llanos, a country rich in pasturage but without agriculture. The Apure itself however is navigated up to its junction with the Rio San Domingo, and the latter is then navigated to a small place called Torunos, at some distance south of the town of Varinas. The agricultural produce of the countries along this part of the Andes is thus brought down to Angostura, and thence exported to Europe.

Among the rivers which join the Orinoco from the right, only the Caroni requires to be mentioned; it drains a long valley in the Parime Mountains, rising east of the source of the Orinoco, and north of the upper branches of the Rio Branco, an affluent of the Guainia, in the Sierra Pacaraima, and running mostly in a northern direction. The current is very swift, and much interrupted by rapids; near its mouth it descends by a cataract fifteen feet high: but the wide valley through which it flows is rich in agricultural products, which include every kind of intertropical fruits and grains, and the Cascarilla del Angostura (*Bonplandiana trifoliata*). The Caroni runs more than 300 miles. The whole course of the Orinoco, so far as it is known, is estimated by Humboldt to be nearly 1300 miles, or equal to that of the Danube.

The tides are perceptible as far as Angostura, or nearly 250 miles from its mouth, in the month of April, when the river is lowest. At the confluence of the Caroni, more than 150 miles from the mouth, the water at that time rises fifteen inches. During the rainy season the Orinoco inundates the greatest part of the Llanos, or plains which lie to the north of it, and likewise a portion of the plains which extend west of its middle course to the base of the Andes. Immediately after the vernal equinox the rising of the water is perceptible: at first it rises slowly, only an inch in twenty four hours, and sometimes the river sinks again in April. It attains its highest level in July, and remains stationary from the end of July until the 26th of August, when it begins to decrease progressively, but more slowly than it increased. It is lowest in January and February. At Angostura the mean rise does not exceed twenty-four or twenty-five feet, but in the upper part of its course it rises several feet higher.

(Humboldt's *Personal Narrative, &c.*; Depon's *Voyage à la Partie Orientale de la Terre Ferme dans l'Amérique Meridionale*; Schomburgk, *London Geographical Journal*, vol. x.)

ORIOLE (*Oriolus*) the name used by Linnæus and authors generally to designate a genus of Merulidæ, which the reader will find characterised in that article. [Vol. xv., p. 123.]

Woods and thickets are the haunts of the Orioles; and there they live in pairs, congregating however for their autumnal migration. Their nests are very artificially framed, and constructed at the extremities of the branches of high trees; insects, with different kinds of berries and other soft fruits, form their food. The prevailing colour of the plumage of the males is yellow, and this character is constant in the greater number of species known. The females differ much from the males, their plumage exhibiting greenish or tarnished yellow tints; and the young in early life always resemble the females. Their moult is simple and ordinary.

Geographical Distribution of the Genus.—Asia, Africa, islands of the Indian Archipelago, and Southern and Eastern Europe.

Example, *Oriolus galbula, the Golden Oriole.*

Description.—Male—Golden yellow, a blackish brown spot between the eye and the bill; wings and tail black; a yellow spot on the quills, not far from the middle of the wing when closed; and the tail-feathers terminated with yellow; bill reddish maroon; iris red; feet bluish grey. Length rather more than ten inches. Mr. Hoy agrees with Mr. Yarrell that the male does not obtain its brilliant yellow and black till the third year.

Female.—Greenish olive above; greyish white with a yellowish tint below, where the plumage is marked by somewhat distant greyish brown short stripes or dashes disposed longitudinally; wings brown bordered with olivaceous grey, tail greenish tinged with black; yellowish beneath with a brownish black mark, somewhat in the form of an irregular V; no dark streak behind the bill and the eye.

The Young of the year resemble the female; but the longitudinal stripes of the lower parts are more numerous and deeper in colour; bill blackish grey and iris brown.

Variety, with black spots on a brilliant yellow ground.

This is supposed by Belon and others to be the Χλωρίων of the Greeks; *Galgulus, Vireo*, and *Oriolus*, Lat., and the *Picus* of which Pliny (book x., c. 33) speaks as suspending its nest on a twig of the topmost branches of a tree, after the manner of a cup. It is the *Beccafigo, Brusolo, Galbero, Garbella, Giallone*, and *Gravalo gentile* of the modern Italians; and *Rigogolo commune* of the *Stor. degl. Ucc.*; *Turo* of the Spanish; *Loriot, Compère loriot*, and *Oriol* of the French; *Gelbe Racke, Gelber Pirol, Der Pyrold, Wiedewall*, &c. of the Germans and Netherlanders; *Goudmerle* of the Low Dutch; *Witwall* of Willughby and Ray; and *y Fwyalchen felen* of the ancient British.

Habits, Reproduction, &c.—*The Golden Oriole* is, upon the whole, a shy bird, haunting lonely groves and thickets on the skirts of woods, excepting in the fruit season, when it always frequents orchards, to the no small loss of the owner. It is difficult to get near them, though they are sometimes approached by the sportsman under the deception of his imitative whistle; but it requires great accuracy both of lips and ear to perform this fraud, for the least mistake, or one false note, will send the bird off at once. The food consists of insects and their larvæ, berries, and fruits, among which figs, grapes, and cherries are favourites. The whistle of the oriole is loud but flute-like, and Bechstein expresses the sound by the word *puhlo*. The cup, or rather saucer-shaped nest, is formed of wool and slender grass-stems, and placed in the fork of a branch, usually towards its extremity. The old French quatrain says,—

'[illegible]
[illegible]
[illegible]
[illegible]'

Nest of Golden Oriole.

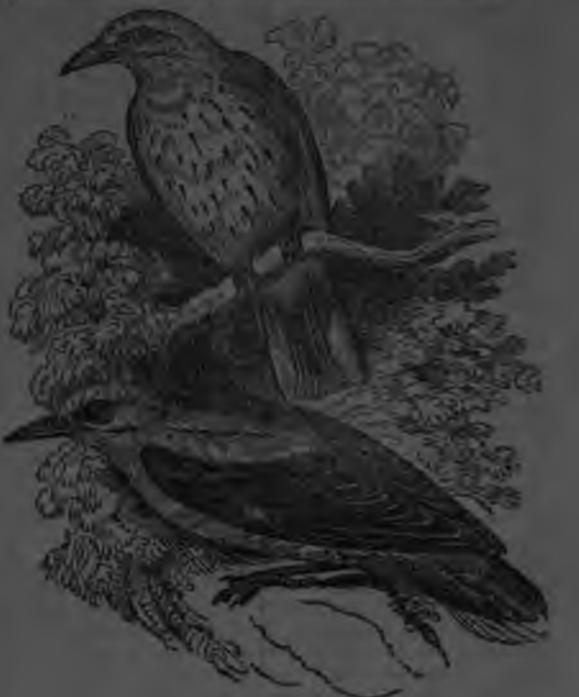
The eggs are generally four or five, purplish white with a few ash-grey and claret spots; and the female watches over them with such maternal care, that it is said she will suffer herself to be taken rather than abandon them. In this country nests have been taken in Suffolk and Norfolk.

Geographical Distribution.—Sweden, where it occasionally breeds; some of the districts of Russia, Germany, Holland, France, Spain, and Italy; Malta (on the southward migration to Africa); Greece, Egypt, Tunis, Tripoli, and the whole north coast of Africa; Trebizond, and Smyrna. In a note to Pennant's *British Zoology*, by J. L., it is stated that it is common in India under the name of *Pilluck* or *Peelach*, and that drawings of both sexes were sent from India to Lord Valentia; but these were probably specimens of *Oriolus aureus* so often received from India, a species which though in some degree like the *Oriolus galbula*, is distinct from it.

In our own country the *Golden Oriole* has been found in Hampshire, Devonshire, Cornwall, near Manchester, near Lancaster, near Welton in Surrey and near Godalming, at Cheshunt (Herts), near Saxmundham in Suffolk, in Norfolk, at Tynemouth in Durham, and in South Wales. It has been seen, though rarely, in Ireland, but never, as far as we can learn, in Scotland.

The bird can only be considered as an *occasional* summer visitor in Britain, where it first appears in *April*, returning in September. The Prince of Musignano states (*Specchio Comparativo*) that it arrives near Rome in the spring, and departs in the autumn.

Utility to Man.—The Golden Oriole gets very fat after its summer feed of fruits. Willughby saw many of them in the poulterers' shops at Naples, and says that 'it hath very delicate flesh, and yields wholesome nourishment.'



Golden Oriole.
Lower figure, male; upper figure, female.

ORIOLI'NÆ. [Merulidæ, vol. xv., p. 123.] Mr. Swainson states that the *Oriolinæ* live in small flocks, fly well, and frequent high trees, among the foliage of which they seek for caterpillars, soft insects, and fruits. (*Classification of Birds*, vol. ii.)

ORI'ON (Constellation). We have already noted the appearance which the Greek astro-mythological system has of being an application of existing fables to a subdivision of the stars derived from the East, mixed perhaps with the Oriental allegories, imperfectly understood. The trivial character of the myths by which the Great Bear and Orion, perhaps the two most remarkable constellations in the heavens, are accompanied, is enough of itself to upset any claim to high antiquity for the system above noted. We owe this brilliant cluster, according to Hyginus (of whose two or three very slight stories this is the most striking), to the fraternal solicitude of Apollo that his sister Diana should remain unmarried, or at least that she should not marry one Orion, a son of Neptune according to some, or of a rather curious parentage according to others. The deity above mentioned, when persuasion had failed, hit upon a method of preventing his sister's match, as follows. He asserted that she could not hit a black object which appeared in the sea at a distance; and she, being a good markswoman, showed him immediately that she could. This black object however was the head of her lover, who was swimming at the time; and the end of it was that, according to custom, he was immediately gazetted as a constellation, with his club and lion's skin.

Orion is surrounded by Eridanus, Canis Major, Gemini, Auriga, and Taurus. The position of his belt, with respect to Aldebaran and Sirius, and the proximity of Procyon, Castor and Pollux, the Pleiades, &c., render it difficult to forget and unnecessary to describe this part of the heavens. The list of stars is as follows: α and β, of the first magnitude, were frequently called Betelguese or Betelgeux, and Rigel, corruptions from Arabic names; γ was called Bellatrix.

ORISSA. [HINDUSTAN.]

ORISSAN LANGUAGE. [HINDUSTAN, vol. xii., p. 227.]

ORITHY'IA. (Crustacea.) [OXYSTOMES.] Orithyia, or Orythia, as it is incorrectly written, is also the name for a genus of Medusarian Pulmogrades. [PULMOGRADA.]

ORIZONTE. The name of this artist was John Francis Von Bloemen, but the Bentvogel Society, consisting of Flemish painters resident at Rome, gave him the name of Orizonte, from the hot and vapoury air of his pictures, it being their custom to give to every new member, on his introduction, a name expressive either of any perfection or defect in his figure and countenance, or some peculiarity in his style, or singularity in his character. Orizonte was born in 1656, at Antwerp, but studied and always resided in Italy. The palaces of the pope and of the nobility at Rome possess abundance of his works, both in fresco and oil. The composition of his landscapes and the character of his trees are almost always in the style of Poussin; but the general tone is a dark green with a cast of red. His selection of subjects is always picturesque, and the pencilling bold; but his pictures are not always equally finished. As he advanced in age his style degenerated into mannerism, but his originality will always entitle him to a place in the first rank of landscape painters. He died in 1740, at the age of eighty-four.

ORKNEY ISLANDS, THE, are a group of islands belonging to Great Britain. They are situated north of the north-eastern extremity of Scotland, between 58° 44′ and 59° 24′ N. lat., and between 2° 22′ and 3° 25′ W. long. They are divided from the mainland of Great Britain by the Pentland Frith, which is 5½ miles wide at its eastern entrance between Duncansby Head and Borough Point in the island of South Ronaldsha. The flux and reflux of the water during the run of the tides through this strait is broken by the Pentland Skerries, which lie a little more than 4 miles to the north-east of Duncansby Head, and 2½ miles south of the island of South Ronaldsha; and farther westward by the islands of Swona and Stroma, the latter of which lies within 1½ mile of the shore of Caithness. A strong current is thus produced running at the rate of from three to nine miles an hour in various parts of the Frith at one and the same time; a circumstance which causes so much sea in gales of wind as to render the strait very dangerous to deep-laden vessels. There are two lighthouses erected on the Great Pentland Skerry, and another on Dunnet Head, on the south side of the western entry to the Frith, with the assistance of which the strait may be navigated with comparative safety in moderate weather.

The group consists of 67 islands and islets, 27 of which are inhabited; the remainder, called *holmes*, are only visited during the summer for the preparation of kelp or as pasture-grounds. The largest of these islands, called Pomona, or Mainland, extends from south-east to north-west, about 18 miles, and divides the group into two portions. The islands between Pomona and the mainland of Great Britain are called the South Isles, and those north of Pomona the North Isles. Eight of the South Islands and three Skerries and fifteen of the North Isles are permanently inhabited. They contained in 1831 a population of 28,847, viz.:—

Some of the islands have rocky shores presenting abrupt precipices towards the west, and rise in low rounded hills covered with heath, and with a considerable depth of peat-mould. Others are low and flat, with sandy shores. There are no trees on any of the islands, with the exception of a few of small size in the neighbourhood of the town of Kirkwall, although at some remote period they would appear to have been covered with wood, from the numerous remains found imbedded in the peat mosses.

The geological character of these islands is very simple; the whole group, with the exception of a small granitic district near Stromness, consisting of rocks belonging to the old red-sandstone formation. The prevailing rock is a species of sandstone flag, much charged with argillaceous matter. It occurs in distinct strata, usually slightly inclined, forming hills of small elevation inland, which however often present very magnificent cliffs round the coasts. The colour varies from pale greenish to blackish grey. Occasionally it contains bitumen, and it is the repository of remarkable fossil fishes.

Connected with the sandstone flag are beds of common sandstone of a yellowish or tile-red colour. It forms the chief part of the mountains of Hoy, the highest point in Orkney, and also several headlands in Pomona and Eda. Dykes of basalt and greenstone traverse these rocks in Hoy

* π¹, π², π³, π⁴, π⁵, and π⁶ of Bayer are g, π¹, r, π², s, and t in modern catalogues.

† So marked by Flamsteed, and denoted by ¹, it should have been 63.

[illegible], &c., and a bed of basalt was noticed by Dr. Traill in Hoy.

The granite tract appears in the form of a chain of moderate hills, occupying a length of six miles, and a breadth of from one to half a mile, and ends at Stromness. It is everywhere in immediate contact with a coarse conglomerate, consisting of nodules of quartz, and fragments of gneiss and sandstone, imbedded in an arenaceous base. The gneiss, conglomerate, and sandstone flag, above mentioned, strikingly resemble the corresponding rocks in Caithness and Sutherland. Fossil fishes occur rather plentifully in Pomona, in the lower beds of a quarry of sandstone flag. The fishes from Caithness and Orkney approach one another very nearly, but among the latter are several new species and even genera. Two of the most remarkable are named, by Agassiz, Chiracanthus and Cheirolepis. (Traill and Agassiz, *Reports of the British Association for 1834*.)

According to a rough estimate, the surface of the islands is [illegible] acres, of which less than one-third is cultivated and used as pasture; the remainder is a waste or covered with water. The island of Sanda, which is flat and low, is the most fertile, and accordingly is called the granary of the Orkneys. Ward Hill, on the island of Hoy, has an elevation of 1555 feet, and is considered the highest land in the islands; Wideford Hill on Pomona also rises to a considerable elevation. The coasts of Pomona and the South Isles are very irregular in their outline, and contain several safe and spacious harbours.

As the Orkneys lie open to the wide expanse of the Atlantic and are exposed to the western gales, which are the prevalent winds, the climate is rather wet than cold. Frost rarely continues for several days in succession, and the harbours are open all the year round. The winter is disagreeable on account of the frequent rains, sleet, and storms, and it is usually prolonged far into the spring, which season also is very damp. The summer is generally fine and pleasant, the heat being very moderate and the weather steady. The early part of the autumn is likewise agreeable, but in November the bad weather commences.

The soil of some of the islands is of inferior quality, but that of others is excellent. Agriculture is limited to the raising of oats, and that kind of barley which in Scotland is called bear, or bigg, and to the cultivation of potatoes, turnips and a few other vegetables. Owing to the proprietors having turned their attention for many years exclusively to the kelp manufacture, agriculture has been greatly neglected; but of late great improvements have taken place, and the opening of a regular steam communication with Aberdeen and Edinburgh has given a great stimulus to the raising of green-crops and rearing of cattle, for which the islands are peculiarly adapted. Owing to the wetness of the climate and the lateness of the summer, wheat is not found to answer, but oats, barley, and big or bear, are exported in considerable quantities. Cattle are numerous, but small; on several of the larger farms the Angus and short-horned breeds have been introduced with success. Horses are abundant, but small. Sea-fowl abound on most of the smaller islands. Many families subsist entirely on the produce of their fishing; cod, herrings, and lobsters abound along the coast, and seals are common. It has been conjectured that the islands derive their name from the seal, ork, in the language of the Northmen, signifying a seal. A few years ago the inhabitants derived a great profit from the preparation of kelp. But for the last five or six years the manufacture has been almost extinct, the article having been quite superseded in the soap and glass works by the carbonate of soda made from common salt. During the war the price of kelp has been as high as 20*l.* a ton, and for many years it was never below 12*l.* Latterly it has sold for about 3*l.* or 4*l.* a ton, which hardly pays the labour of making it and sending to market. The little kelp which is still made is used chiefly in the preparation of iodine. Owing to the extinction of the kelp manufacture a complete change has taken place in these islands. Under the old system the mass of the population were, in all but name, serfs attached to the soil, being bound to labour at kelp-making for the landlord in exchange for a miserable cottage and little patch of land, and living from year to year without hope or prospect of bettering their condition. The failure of the market for kelp in fact emancipated them, as their labour ceasing to be valuable to the landlord, they were left at liberty to employ it in any occupation which they found most advantageous. The consequence has been a great extension of agriculture and the rise of the herring-fishery, which had been entirely neglected, into a branch of industry of great importance. Upwards of 700 boats, with six men each, and of the average value, with their nets, of 130*l.* or 140*l.*, are now employed in this fishery, and the number is rapidly increasing. In favourable years from 30,000 to 40,000 barrels of herrings are exported, and from 20,000*l.* to 30,000*l.* are divided among the fishermen and their families. The cod-fishery also, which is prosecuted in the months of May and June, before the great shoals of herrings appear on the coast, is fast rising into importance, and already brings from 5000*l.* to 7000*l.* annually into the country. The lobster-fishery is also carried on, but is of minor importance.

The inhabitants are of Scotch and partly of Norwegian descent. While the islands belonged to Norway and Denmark, many Norwegians settled on them, and their language was exclusively in use. But since the islands have been annexed to Scotland, a great change has taken place, and the Norse language has been long extinct. A few relics of the Udal tenure, the universal tenure of land among the free nations of the north, may still be found; and there are instances of families who occupy small patches of ground which have descended from father to son from time immemorial. In character, manners, and language the inhabitants of these islands now differ little from the Scotch lowlanders. They are generally intelligent, educated, and moral. The competition between the United Seceders, who constitute about a third part of the population, and the established church, has done much of late years to extend the means of education and diffuse a spirit of religious zeal. There are few parishes which have not at least two schools. The women find some occupation in straw-platting. A number of young men leave the country to enter the merchant navy, and often rise to be masters and mates of vessels, being in general sober, honest, and able to read and write. Formerly a considerable number went to America in the service of the Hudson's Bay Company, but since the junction of the Hudson's Bay Company with the North-West Company, Canadians have been exclusively employed. A few men also go every year with the whale-ships to Davis's Straits, but, owing to the rapid increase of the herring and cod fisheries of late years, the number who leave the islands in search of employment is considerably diminished.

It appears that the Orkneys were early taken possession of by the Normans, and they remained subject to the kings of Norway and Denmark till the year 1468, but had their own kings or earls, who governed them as independent sovereigns. The Orkneys were the general rendezvous of the piratical fleets which so often devastated the coasts of England and France. Rollo, the conqueror of Normandy, and ancestor of William the Conqueror, was an earl of Orkney. In 1468 the islands were pawned to Scotland for 50,000 florins, and the pledge has never been redeemed. From the year 1471 the earls of the island became dependent on Scotland, and from that time were considered like other chieftains of the Scottish clans.

Kirkwall, situated on a bay on the north coast of Pomona, is the capital of the islands. The cathedral of St. Magnus at Kirkwall is one of the most remarkable specimens of middle age architecture in Scotland; it was built by Olave, king of Denmark. It is in good repair and still used as the parish church. Close to the cathedral are the ruins of the bishop's palace, and of the palace of Earl Patrick Stewart, the last feudal earl of Orkney, who was executed for high treason in the reign of James I. The town consists of one long narrow street, but contains several good houses and shops. It has been recently lighted with gas. The population in 1831 was 3721. It has ten schools and a considerable trade in the produce of the island. In 1834, 78 vessels, of 4236 tons, navigated by 326 seamen, belonged to this port. In 1834 the shipping which left the port amounted to 8249 tons, and 10,204 tons entered. The town has some distilleries.

Stromness, situated towards the south-western extremity of Pomona, has also a good harbour. It contained in 1831 a population of 2921, and it has considerable trade: about 300 vessels annually enter the harbour.

Though there are several other good harbours, they are not used, except by fishing-boats; the best in Orkney is Inganess Bay for all classes of vessels. The principal stations for the herring-fishery are St. Margaret's Hope in South Ronaldsha and [illegible] in Stronsa. On the island of Hoy there is an excellent and spacious harbour, called Long Hope. The stewartry of Orkney and Shetland, consisting of this group and the Shetland Isles, sends one member to parliament, and the town of Kirkwall, which is a royal borough, returns a member together with Wick, Dingwall, Tain, Cromarthy, and Dornoch.

(Peterkin's *Notes on Orkney and Zetland*; Neill's *Tour in Orkney and Zetland*; Stanley's *Voyage to the Orkneys*; Sheriff's *Agricultural Report of the Orkneys*; *Various MS. Communications.*)

ORLAY, BERNARD VON, called Bernard of Brussels, was born in that city about the year 1490. He went to Rome when he was very young, where he had the good fortune to become a pupil of Raphael. On his return to Brussels he was appointed principal painter to the governess of the Netherlands, and was likewise employed for many years by the emperor Charles V.

The style of his design was noble, and his tone of colouring very agreeable. He very frequently painted on a ground of leaf-gold, especially if he was engaged on a work of importance, a circumstance which is said to have preserved the freshness and lustre of his colours: in his hunting pieces, in which he introduced portraits of Charles V. and the nobles of his court, he usually took the scenery from the forest of Soignies, which afforded him ample variety.

He was engaged by the Prince of Nassau to paint sixteen cartoons, as models for tapestry, intended for the decoration of his palace. Each cartoon contained only two figures, a knight, and a lady on horseback, representing some members of the Nassau family. These cartoons were designed in an elevated style worthy of a pupil of Raphael. The cartoons were afterwards copied in oil, by Jordaens, by the prince's order. The chapel of a monastery at Antwerp had a celebrated picture of the Last Judgment by this master: we are not certain whether it is still there, or has been lost or destroyed in the scenes of revolution and confusion of the last half-century. B. von Orlay died in 1560, aged seventy.

As this artist is, we believe, little known in England, we subjoin a few brief notices from Dr. Waagen's 'Arts and Artists in England,' respecting pictures which he saw in English collections: 'In Devonshire-house, Neptune and Amphitrite, and Cupid with the trident, a very carefully executed little picture, here ascribed to Luca Penni, but, beyond all doubt, a work of that Flemish scholar of Raphael' 'At Chiswick: 1, a female portrait, very delicately painted, kept under glass, and, without any reason, said to be Petrarch's Laura; 2, a female figure in profile, called Cleopatra, on account of a serpent on the bosom; but the expression of indifference in the fine and handsome face does not correspond with the character.' In the Liverpool Institution: a Holy Family, admirably executed, after a composition by Leonardo da Vinci. At Chatsworth: the Presentation of the Virgin in the Temple, a very rich composition, ascribed to Jan van Eyck; but many parts of which, says D. Waagen, 'strongly remind me of the admirable Bernard von Orlay.' At Keddleston Hall, the seat of Earl Scarsdale: the Virgin with the Infant Christ, who blesses St. John in the presence of Joseph and Elisabeth: the figures are three-quarters the size of life. Dr. W. says that next to the Pietà, in the museum at Brussels, this is the finest picture that he is acquainted with by this eminent master. At Lord Spencer's, at Althorpe: a bust of Anne of Cleves, very carefully painted

ORLE'ANOIS, or ORLE'ANAIS, L', one of the provinces or military governments into which, before the Revolution, France was divided. It was bounded on the north and north-east by the government of L'Ile de France, on the east by Champagne and Bourgogne, on the south east by Nivernois, on the south by Berri or Berry, on the south-west by Touraine, and on the north-west by Maine and a small part of Normandie. It took its name from Orléans, its capital [ORLEANS], and comprehended the subordinate districts of Orléanais, properly so called, chief town Orléans, pop. 40,161; Le Gatinois Orléanois [GATINOIS], chief town Montargis, pop 6781; Le Blaisois or Blésois [BLESOIS and BLOIS], chief town Blois, pop. 13,138; La Sologne, chief town Romorantin, pop. 6985; and La Beauce or Beausse [BEAUCE], which comprehended the three subordinate districts of Le Pays Chartrain [CHARTRAIN], chief town Chartres, pop. 14,139; Le Dunois [DUNOIS], chief town Châteaudun, pop. 6461; and Le Vendômois, chief town Vendôme, pop. 7771. The province of Orléanois is now divided into the departments of EURE ET LOIR, LOIR ET CHER, and LOIRET. Small portions of it are comprehended in the departments of NIEVRE, SEINE ET OISE, and YONNE. It included the three bishoprics of Orléans, Chartres, and Blois, all of which still exist. The bishops are suffragans of the archbishop of Paris.

Orléanais, properly so called, was conterminous with Beauce on the north, north-west, and west, Gatinois on the north-east and east, Sologne on the south, and Blésois on the south-west. It comprehended, besides Orléans, the towns of Beaugency, pop. 4883; Châteauneuf, pop 3160; Meung, pop. 4630; and Pithiviers, pop. 3957. It is at present included in the department of Loiret, except a very small portion which is in the department of Eure et Loir.

The district of Orléanais, in the wider application of the term, was for the most part included in the country of the Carnutes, and in the Roman province of Lugdunensis Quarta, or Senonia; a portion of it was included in the territory of the Senones, in the same province: both these were Celtic nations. It was one of those parts of Gaul which remained longest in the hands of the Romans; but after the defeat of Syagrius by Clovis, it fell into the hands of the Franks. The part south of the Loire was probably already in the hands of the Visigoths, from whom it was soon after taken by the Franks. It was probably included in the kingdom of Orléans under the sons of Clovis, and in that of Neustria under the later descendants of the same monarch. Part of it at least was included in the domains of Hugues Capet, before his accession to the throne of France, upon which event it became part of the domains of the crown.

ORLE'ANS, a town in France, capital of the department of Loiret, situated on the right bank of the Loire, 65 miles in a direct line south by west of Paris, or 71 miles by the road through Montlhéry, Etampes, and Artenay; in 47° 55′ N. lat. and 1° 53′ E. long.

Orléans is a town of considerable antiquity. We are of opinion, with D'Anville, that it was the Genabum of Cæsar, in opposition to the opinion of those who would fix Genabum at Gien. (See art. 'Genabum,' in the 'Index Geographicus,' subjoined to the edition of Cæsar in Lemaire's '*Bibliotheca Classica Latina*, Paris, 1822.) This Genabum was a trading town of the Carnutes, a Celtic people, and was the scene of the outbreak of the great revolt of the Gauls against Cæsar, in the seventh year of his command. The Carnutes, under the command of two desperate leaders, Cotuatus and Conetodunus, assembled in the town, massacred the Romans who for commercial purposes were residing there, among whom was one of the officers of Cæsar's commissariat, and despatched the intelligence with unexampled rapidity to the surrounding states. In consequence of this outrage, Cæsar, early in the ensuing campaign, attacked the town, which he plundered and burnt. (Cæsar, *De Bello Gallico*, lib. vii., c. 3, 11.) It seems to have recovered from this disaster, and in the time of Strabo, who calls it Γήναβον, was again the emporium or trading town of the Carnutes. At a subsequent period it was made the capital of a separate district, and received the name of Aureliani, as it is commonly supposed from the emperor Aurelian, but this we think very doubtful. The modern name Orléans is obviously derived from Aureliani, or, as it was written in the middle ages indeclinably, Aurelianis.

In the devastating invasion of Attila (A.D. 451) that barbarian penetrated as far as Orléans, which he besieged. The town had been strengthened with new fortifications, and was bravely defended by the townsmen and the garrison until it was relieved by the timely approach of the Romans and Visigoths under Aetius and Theodoric. Orléans subsequently passed into the hands of the Franks, and became the capital of one of the kingdoms into which their territories were so frequently divided. In subsequent centuries the town was the object of the hostility of the Saxons and Normans, the latter of whom twice captured it (A.D. 855 and 865). It was the capital of a county which was included in the territories of the dukes of France, and on the accession of Hugues Capet, who had inherited that duchy, became one of the most important places in the immediate dominions of the crown. It was at a later period (A.D. 1428) besieged by the English under the regent Bedford [BEDFORD, JOHN, DUKE OF], but the siege was the limit of their successes. They were obliged to raise it with disgrace, and never after recovered their superiority. [ARC, JEANNE D'.] At this time the town gave the title of duke to a branch of the hou of Valois, which afterwards came to the throne in the person of Louis XII.

In the religious wars of France in the sixteenth century, the prince of Condé, leader of the Huguenots, early in the struggle possessed himself of the town of Orléans (April, 1562). In less than a year (February, 1563) it was besieged by the duke of Guise at the head of the Catholics; but his assassination [GUISE OR GUYSE, DUKES OF] prevented the capture of the place. At the peace concluded soon after, it was restored to the king. In 1567 it was surprised on the renewal of hostilities by La Noue, a Huguenot captain. The capture did much injury to the cathedral and the other churches. It came afterwards again into the hands of the Catholics, and in the massacre of St. Bartholomew (A.D. 1572) a number of Huguenots, variously stated at from 500 to 1800, perished at Orléans.

The town stands in a plain gently sloping down to the river: the circuit of the ramparts, now converted into a promenade, forms an arc of a circle about two miles and a half to three miles in extent. The side of the town along the bank of the Loire, representing the chord, is about a mile and a half, and the length of the principal line of street from the entrance of the Paris road into the town on the north side to the bridge over the Loire, nearly perpendicular to the chord, is about three-quarters of a mile. Orléans is surrounded by numerous country-houses, and has large suburbs, of which that of Olivet (not to be confounded with the little town of Olivet three miles off) is on the south side of the river. Some parts of the town are well laid out, with wide and clean streets and well-built houses. The line of street from the Paris road to the bridge is on the whole the finest, especially that part which lies between La Place du Martroy (the principal square in Orléans, adorned with a coarsely executed pedestrian statue of Jeanne d'Arc) and the bridge. But the parts to the right and left of this line of street are ill laid out, ill built, and ill paved; and the buildings in the eastern part of the city are the most wretched possible. The bridge over the Loire is above 1000 feet long, and consists of nine arches, of which the centre has above 100 feet span. There is a tolerably handsome quay near the bridge; and between the bridge and the suburb of Olivet is a public walk. This suburb abounds with country-houses and with nursery-grounds.

The cathedral of Sainte Croix is one of the finest in France. It was rebuilt after its being ruined by the Huguenots. The rebuilding was commenced by Henri IV., but the edifice has only been finished (if indeed it be yet complete) since the restoration of the Bourbons. The architecture has excited much admiration, especially that of the principal entrance; and the two towers of the front are said to surpass in elegance and lightness the finest specimens of Gothic architecture. The church of St. Aignan, the finest except the cathedral, is a beautiful Gothic building, but is imperfect. The nave was destroyed by the Huguenots, and the steeple was demolished not long since. The church of St. Pierre le Puellier, the oldest in the town, is remarkable only for its antiquity. There are a town-hall; a court-house (*Palais de Justice*), a handsome modern building; a building in which is deposited the public library of above 20,000 volumes; and a plain theatre. The botanic garden is little more than a public walk.

The population of Orléans in 1831 was 40,161; in 1836, it was 40,274. The commercial prosperity of Orléans is not equal to what it was formerly. Its refining-houses for sugar were more busily engaged before the rise of this branch of industry in Paris; and the manufacture of hosiery for exportation to the Levant has also declined. The preparation of vinegar, the bleaching of wax, are still actively carried on, and blankets and cotton counterpanes are manufactured. To these articles of manufacture may be added cotton and woollen yarn, fine woollen cloths, flannels, hats, files, rasps, and other tools, glue, chamois and other leather, &c., and earthenware. There are breweries and dyehouses; and round the town are numerous nursery-grounds. The neighbourhood produces some excellent wine. Trade is carried on in the above articles, and in brandy, corn, flour, seed, saffron, fire-wood, timber, planks, coals, groceries, and spices. The navigation of the Loire, and the communication with the Seine and its branches by means of the canals of Orléans and the Loing, contribute much to the trade of the place.

There are a Cour Royale and several other judicial and fiscal government offices; an exchange, a chamber of commerce, and other institutions connected with trade; an Académie Universitaire; a society of sciences, belles-lettres, and arts; a royal college or high school; free schools for drawing, architecture, geometry, and mechanical science as applied to the arts; courses of instruction in medicine; a museum of natural history, and two large libraries. Orléans is the seat of a bishopric, the bishop of which is a suffragan of the archbishop of Paris: his diocese consists of the department of Loiret.

The arrondissement of Orléans comprehends an area of 929 square miles, and includes 106 communes: it is divided into fourteen cantons, or districts, each under a justice of the peace. The population in 1831 was 137,820; in 1836, it was 141,637.

ORLEANS NEW, the capital of the state of Louisiana, is situated on the eastern bank of the Mississippi, 104 miles from its mouth following the course of the river, and about 90 miles in a direct line from the Gulf of Mexico; in 29° 58′ N. lat. and 90° 9′ W. long. The city is in the most favourable situation for the prosecution of the trade of one of the most important parts of the North American Union, being near the mouth of the great outlet to the valley of the Mississippi. It is already the emporium of the vast region which is drained by that river, the Missouri, the Red River, and their tributaries, and in future years, when settlements shall have extended through that fertile region, New Orleans may become the greatest commercial city of the West; there is no place in Europe or America which has equal natural facilities of internal navigation. The rapidity with which the population and commerce of the city have increased during the last 20 years, and especially since the introduction of steam-vessels upon the great western rivers, has been most remarkable; and this notwithstanding the disadvantages of the place being unhealthy. The population of New Orleans, which was 17,242 in 1810, was 27,176 in 1820, and in 1830 amounted to 46,310. The number of French inhabitants is about equal to that of the Americans, but the French predominate in the old town, where many of the storekeepers are unable to speak English. There are many Spaniards, about 12,000 slaves, 3000 free persons of colour, and 14,000 strangers from all parts of the world. In 1803, when the territory was bought by the United States from France [JEFFERSON], the number of inhabitants did not exceed 10,000. New Orleans was founded by the French in 1717; it was ceded to Spain in 1763, with the rest of Louisiana; but was restored to France in 1801, and purchased by the United States in 1803.

The French language is perhaps as much spoken as the English. The principal theatre is French; it is in the old town, is large, and well attended. The American theatre is in the suburbs. Billiard-rooms, gambling-houses, and lottery-offices are in great numbers, especially in the old town. Some of the newspapers are in English, some in French, and some are half in English and half in French.

New Orleans is built in the form of a parallelogram, consisting of six complete squares, with suburbs, called faubourgs. The streets in the old city are about 40 feet wide; many of them are unpaved, but have wide and convenient footpaths. The houses near the river are of brick, but in the rear of the town many are built of wood. During the hottest months of the year the city is exceedingly unhealthy, and many of the wealthier inhabitants leave it at that season; of those who remain, a large proportion are carried off yearly by yellow fever. The climate is however more fatal to Europeans who are new comers than to natives; and perhaps in addition to the insalubrity of the place, we must take into account the dissolute mode of life of many of the inhabitants as one cause of the great annual mortality. The disease is most probably caused by the marshy nature of the soil in which the town stands, and the exhalations with which the air is consequently loaded. This disadvantage is hardly susceptible of remedy, because the city stands a few feet below the level of the Mississippi, the waters of which are kept in their channel by an artificial mound, or *levée*, which extends for nearly 100 miles along the bank. The sickly season extends through the months of July, August, and September. The musquitos are in vast numbers. Every bed in every respectable house is provided with a musquito-curtain.

The cathedral is the only public building at all imposing; it has four towers, and massive walls ornamented with figures of saints in the niches. There is a large 'Charity Hospital,' which provides liberally such articles as are needed by the sick poor, and relieves every year from 8000 to 9000 patients. There are also three orphan asylums for supporting, educating, and putting out in the world destitute orphans: two of these institutions are well endowed, and the whole are well supported by the richer inhabitants.

In the environs there are large plantations of sugar, cotton, indigo, and rice, which are cultivated in a very perfect manner. There are pomegranates, magnolias, myrtles, and the fragrance of the orange groves, when the trees are in blossom, is delicious.

A canal, opened in 1837, connects New Orleans with Lake Pontchartrain. It is 4½ miles long, and cost nearly a million of dollars. Another canal, called the Carondelet canal, connects the Mississippi with Lake Pontchartrain through the river Saint John. La Fourche Canal extends from near New Orleans to Berwick's Bay; the length, including the natural navigation, is 85 miles. A railroad, 4½ miles long, connects New Orleans with Lake Pontchartrain. This work is perfectly straight, and with a difference in the level of only 16 inches throughout: it has cost half a million of dollars, and produces an adequate return. At the terminus of this line on Lake Pontchartrain, an artificial harbour and breakwater have been constructed. The Carrolton railroad connects the city with Carrolton, 6 miles distant, and with Lafayette, 2 miles distant. The entire length of the main-line and branches is 11½ miles: this work has been very profitable to the projectors. A third railroad, 1½ miles long, connects New Orleans with the Bayou St. John. Several other lines of railroad are in progress.

New Orleans is supplied with water by a public company, which has laid down 12 miles of pipes. The water is pumped from the river to a reservoir 30 feet high, where it is allowed to settle, and is thence distributed through the city. The city water-works is another establishment, used in the hot season only to pump water from the river and to convey it in open channels through the streets. A draining company has erected two steam-engines for draining the swamps between the city and Lake Pontchartrain, by which means an extent of about 35 square miles of land is reclaimed with great advantage to the adventurers, and benefit to the health of the inhabitants.

The shipping, registered and enrolled, that belonged to the port of New Orleans, in 1836, were of the burthen of 81,710 tons. The vessels that entered and cleared in that year were as follows:—

	Entered.		Cleared.	
	Ships.	Tons.	Ships.	Tons.
American .	503	95,833	632	147,838
Foreign .	210	50,294	190	48,110
Total .	713	146,127	822	195,948

The import and export trade of the state of Louisiana, nearly the whole of which centres at New Orleans, was as follows, in the year ending 30th September, 1838:—

	Imports. Dollars.		Exports. Dollars.
In American vessels .	7,342,614	Domestic produce .	30,077,534
Foreign do. .	2,154,194	Foreign do. .	1,424,714
Total	9,496,808	Total	31,502,248

The greater part of the domestic produce exported consisted of cotton.

New Orleans is distinguished for the courageous and successful defence which it made against the English in January, 1815. The English were commanded by Sir Edward Pakenham; the American defence was conducted by General Jackson. A breastwork was raised in front of the city, and strengthened by bales of cotton, which were brought in great quantities. Behind these cotton-bags General Jackson placed picked riflemen, each of whom had one, two, or three men behind him to load his rifles. The English were first exposed to a terrible fire of artillery within half cannon shot, and afterwards to the rifles and small-arms of the Americans. The British are understood to have [illegible]d between 10,000 and 12,000 men in this engagement, the Americans between 3000 and 4000. The British etween 3000 and 4000 men; the Americans had only seven wounded. Sir Edward Pakenham was killed.

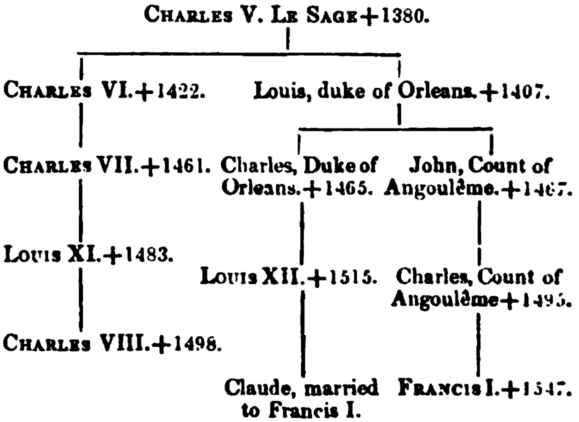
ORLE'ANS, HOUSE OF, the title of a branch of the royal family of France, which has three times originated in the younger son of a king, and has twice obtained possession of the crown.

I. The first House of Orleans sprang from Louis, second surviving son of Charles V., the earliest prince who appears to have borne the title of Duke of Orleans, and who, after playing a conspicuous and not very creditable part in the troubles which agitated the reign of his imbecile brother Charles VI., was assassinated at Paris, in 1407, by his cousin and rival John, surnamed *Sans Peur*, duke of Bourgogne. The results of this crime were most disastrous to France, which was filled with violence and bloodshed by the conflict of the two factions of the Bourguignons and Armagnacs: the Orleans party being distinguished by the latter title, from their leader, the count of Armagnac, who, as father-in-law of the young duke of Orleans, undertook to protect his cause, and avenge the murder of his father. The history of the first duke of Orleans is also memorable for his marriage with Valentina Visconti, daughter of Gian Galeazzo Visconti, duke of Milan, which eventually gave the house of Orleans pretensions to that duchy, and produced the Italian wars of Louis XII. and his successors for its possession.

The life of Charles, second duke of Orleans, was remarkable chiefly for his having been taken prisoner by the English at the battle of Azincourt, in consequence of which he suffered a long captivity, together with his younger brother John, count of Angoulême. Dunois, the famous 'Bastard of Orleans,' and progenitor of the house of Longueville, was his illegitimate brother.

Louis, son of Charles, and third duke of Orleans, was exposed, during the reign of Louis XI., to the splenetic jealousy of that gloomy tyrant, whose deformed daughter Jane he was compelled to marry: but on the death of Charles VIII., and the failure of the direct line of Valois, in 1498, the duke of Orleans succeeded to the crown by the title of Louis XII. On his own death, without male issue, in 1515 [Louis XII.], his cousin Francis, count of Angoulême, to whom he had given his daughter Claude in marriage, ascended the throne, under the title of Francis I.: and the royal succession thus devolved upon the second branch of the House of Valois-Orleans—or line of Valois-Angoulême, as it has been called—which contributed five sovereigns to France, viz. Francis I., Henry II., Francis II., Charles IX., and Henry III.

The following table will show the descent of the first house of Orleans.



CHARLES V. LE SAGE + 1380.
CHARLES VI. + 1422.
Louis, duke of Orleans. + 1407.
CHARLES VII. + 1461.
Charles, Duke of Orleans. + 1465.
John, Count of Angoulême. + 1467.
LOUIS XI. + 1483.
LOUIS XII. + 1515.
Charles, Count of Angoulême + 1495.
CHARLES VIII. + 1498.
Claude, married to Francis I.
FRANCIS I. + 1547.

II. The only prince of the second House of Orleans was Jean Baptiste Gaston, the younger of the two sons of Henry IV. and Maria de' Medici, who was born in 1608, created duke of Orleans in 1626, and died in 1660. Of a vain and unquiet, weak and heartless character, his life was a series of troubles and disgraces, which were caused principally by his own misconduct. During the reign of his brother Louis XIII., he was continually engaging in intrigues and conspiracies against Cardinal Richelieu: and, on their failure, purchased safety by his own humiliation and the base sacrifice of his unhappy accomplices. In 1626 he countenanced a plot against the life of the cardinal; and, on its detection, abandoned the Count de Chalais, one of the principal officers of his household, to the vengeance of the minister, who had his head struck off. Five years later, Gaston retired from court on some new quarrel with Richelieu, incurred the displeasure of his brother by contracting a marriage with Marguerite, sister of the duke of Lorraine, and finally withdrew into exile at Brussels, leaving his adherents again exposed to the persecution of the cardinal. At length, he re-entered the kingdom in open arms against the royal authority, but persevered in hostilities only until he was defeated at the combat of Castelnaudary, in which his principal partisan, the duke of Montmorenci, was made prisoner; when he obtained pardon for himself, without security for his captive friend, who was brought by the relentless Richelieu to the block. Gaston retired on this catastrophe again in terror to Brussels; but with his usual levity he was, after some time, induced to abandon his Spanish protectors and return to the court. Being entrusted with the command of an army against the Spaniards, he formed, in 1636, in conjunction with the Count de Soissons, another plot to assassinate the cardinal, caused the failure of the design by his irresolution, and on its exposure fled to Blois, but was soon after again reconciled with the court. The birth of a son to Louis XIII., by giving an heir to the monarchy, diminished the importance of the Duke of Orleans in the state; and he fell into comparative obscurity for some years, until, in 1642, it was discovered that he had entered into a treasonable treaty with Spain, for the subversion of the monarchy and the murder of the cardinal. The mean-spirited duke saved his own life, according to his custom, by the most abject submission, and by betraying his accomplices, among whom the young Marquis de Cinq Mars, a favourite of Louis XIII. himself, and François Auguste De Thou, son of the famous historian, were the principal victims. Gaston himself, on this occasion, did not escape without the loss of the honours due to his birth. He was deprived of his guards and his principal domains, and banished from the court. But the death of Richelieu and of Louis XIII. shortly changed the aspect of affairs; and in the minority of his nephew, Louis XIV., the Duke of Orleans was called to the post of lieutenant-general of the kingdom, under the regency of the queen mother, Anne of Austria. He gained some credit in the campaign of 1644 against the Spaniards, and for a time supported the government of the regent and her minister Cardinal Mazarin. But the absurd commotions of the *Fronde* soon tempted the characteristic levity of Gaston; and he allied himself, against the court and Mazarin, successively with the Prince of Condé and with the parliament of Paris. The latter body were moved by his cabals, though Louis XIV. had now attained his majority, to appoint him anew lieutenant-general of the kingdom, as the same title had been factiously conferred on the Duke de Mayenne in the time of the League. But the final triumph of Mazarin and the close of the civil wars produced for Gaston the usual fruits of his vacillation and perfidy; and in 1652 he was banished from the court to Blois, where he passed the remaining eight years of his life in mortification and contempt.

Gaston had no male issue; but he was the father, by his first marriage, with the heiress of Montpensier, of the princess who inherited that title, and who figured so conspicuously in those strange political scenes of her times, of which she has left her own memoirs. Louise de Montpensier, known among her contemporaries as 'La Grande Mademoiselle,' merited that designation as much by her aspiring character as her illustrious birth. She shone conspicuously in that galaxy of high-born French women who, more distinguished for their masculine spirit and wit than for the becoming virtues of their sex, ruled the ascendant throughout the political storms of the Fronde. While heroes and statesmen bartered their honour and policy for the smiles of beauty, while fortresses were surrendered to fair ladies' eyes, and treaties were made and broken with lovers' vows, these female warriors and politicians openly appeared in the camp and the council. Gaston of Orleans, in a style as much curious as burlesque, addressed a letter to 'Mesdames les comtesses, maréchales-de-camp in the army of my daughter against Mazarin.' With more boldness than her father, the Grande Mademoiselle showed her prowess by turning the guns of the Bastile against the royal troops to cover the retreat of the forces of Condé. 'That discharge has killed her husband,' said Mazarin, in allusion to her well-known ambition to espouse her cousin, the young king Louis XIV., whose regard was for ever alienated from her by this exploit. After having aspired to be queen of France and having refused the hand of several other sovereigns, Mademoiselle de Montpensier finished, at the mature age of forty-four years, by desiring to raise a private nobleman, the Count de Lauzun, to the rank of her husband and the title of duke of Montpensier. Louis XIV. first granted and then unkindly retracted his consent to the union; notwithstanding which it was privately concluded in 1670, an offence for which Lauzun suffered a ten years' imprisonment. After she had obtained his release by the sacrifice of her finest domains to a natural son of the king, the princess found her marriage neither recognised at court nor happy in itself; and she closed, in 1693, a life of strong passions, embittered by the disappointment both of political ambition and personal affection.

III. The progenitor of the third and existing House of Orleans was Philip, second son of Louis XIII. and Anne of Austria, who was born in 1640; received the title of duke of Orleans, on the death of his uncle Gaston, in 1660; and succeeded to the duchy of Montpensier, by the bequest of La Grande Mademoiselle, in 1693. His career was by no means distinguished; but he is said to have had some taste for letters; and he served with honour in several of the most glorious campaigns of the reign of Louis XIV. He was twice married; first, to his cousin Henrietta of England, daughter of Charles I., and, like himself, a grandchild of Henry IV.; and secondly, to Elizabeth of Bavaria, daughter of the Elector Palatine. The circumstances which attended the sudden death of his first wife, a princess celebrated for personal graces, in the flower of her age, cast upon him the horrid suspicion of having poisoned her; a charge however apparently as unfounded in itself, as the imputed crime was at variance with the whole tenor of his character, which, though he was too much addicted to the pleasures of sense, was mild and good natured. By the Princess Henrietta, Philip had two daughters, one of whom became the queen of Charles II. of Spain, and the other, through her marriage with Victor Amadeus II. of Savoy, transmitted to the House of Sardinia, after the extinction of the male line of Stuart, as much vain pretension to the inheritance of their crown as could be conveyed by mere descent in opposition to constitutional law. By his second marriage Philip had, besides a prince who died young, and a daughter, the son, of his own name, who, on his death in 1701, succeeded him in his titles.

This was the celebrated Regent Orleans, of whom Voltaire has declared, that 'famed for his courage, his wit, and his pleasures, he was born for society even more than for public affairs, and was one of the most amiable men that ever existed.' The severer judgment of history has branded the memory of Philip II., duke of Orleans, with the reproach of unbounded personal and political profligacy; and the fatal example both of his private life and public administration encouraged that corruption of morals in France, which, becoming aggravated throughout the licentious reign of Louis XV., unquestionably produced the worst excesses of the Revolution. Nature had endowed Philip II. of Orleans with great abilities; but his mind was early tainted by the lessons of his tutor, the able and infamous Dubois, who was afterwards, under his regency, a cardinal, his favourite, and prime-minister. Philip was a proficient in many sciences and accomplishments; in the mathematics, in poetry, music, sculpture, and painting. He had likewise in his youth displayed considerable talents for war, and some ambition to attain equal distinction in arts and arms. He was wounded on several occasions, signalised himself at the battles of Steinkerque and Neerwinden, commanded the French armies with courage and activity in Italy and Spain during the Succession War, and in the latter country established so much reputation and influence, that Louis XIV. is said to have suspected him of a design to supplant Philip V. on the throne of that kingdom. This and other causes of jealousy led Louis XIV., in anticipation of his great-grandson's minority, to meditate the exclusion of Philip of Orleans from the regency. But the death of the aged monarch prevented the completion of this plan; the duke quietly possessed himself of the government, and grievous as were the vices of his administration, he was guilty of no ambitious attempt to abuse the rights of the young king. His frame was worn out by debauchery before he had quite completed his fiftieth year; and a sudden death terminated his career in 1723. He had been married during the life of Louis XIV. to Françoise Marie de Bourbon, styled Mademoiselle de Blois, natural daughter of that monarch and Madame de Montespan.

by whom he had one son, born in 1703, and several daughters.

Louis duke of Orleans seemed at first disposed to emulate the vices of his father, whose better tastes for letters and science he also inherited. But his marriage with a princess of Baden, to whom he became tenderly attached, weaned him from early habits of dissipation; and her premature death, in 1726, affected his mind so deeply, that he withdrew from the world to a monastery. In this retreat he divided the remainder of his life between works of charity, religious exercises, and literary studies; and here, in 1742, he closed an existence dignified with every virtue that could adorn a recluse. Louis left a son and daughter, of whom the former, Louis Philippe, born in 1725, was his successor in the family honours. His life was remarkable only for his military service, in the early part of which he fought with gallantry at the battles of Dettingen and Fontenoy, and subsequently in some of the affairs of the Seven Years' War. He married a princess of the House of Conti, by whom he had a son and a daughter, and died in 1785.

Louis Philippe Joseph, the only son of the last duke, who was born in 1747, and known during his father's life as Duke de Chartres, became afterwards more unhappily distinguished as the Duke of Orleans of the National Assembly, the Louis Egalité of the Convention, the instrument and the victim of the French Revolution. Naturally gifted with a handsome person and superior talents, he had disfigured both mind and body by a youth of debauchery; and in maturer years his infamous reputation exposed him at the court of Louis XVI. to a contempt which he but too well repaid with deadly hatred to the person and family of that monarch. In the year 1778 he was present in the naval action between the squadron of Admiral Keppel and Count d'Orvilliers off Cape Ushant; and he was accused of having behaved in that engagement with such shameful cowardice, that, instead of receiving the advancement to which he aspired in the sea service, he was appointed colonel-general of hussars, a post created for him by the court with the intention, as it was said, of covering him with ridicule. Having, in 1785, succeeded to his father's title, he eagerly entered upon a political career, of which it seems to have been the object, by acquiring popularity, to revenge his injuries upon the court and to raise himself into power. He proved himself however utterly destitute of the qualities of a revolutionary leader, and was soon overwhelmed in the political tempest which he endeavoured to direct. At the commencement of the Revolution he arrayed himself on every occasion against the royal authority: during the progress of events which raised the Jacobin party into power, he became their associate and dupe; to render homage to their opinions as a member of the National Convention, he solicited and obtained permission to renounce the name of his family and assume that of Egalité; and finally, after having voted for the death of Louis XVI., he was himself dragged to the scaffold towards the close of the year 1793. He was married to Louise Marie de Bourbon-Penthièvre, daughter of the duke de Penthièvre, grand-admiral of France, by whom he left one son, the present King of the French, and a daughter, styled Mademoiselle d'Orleans.

ORLOFF, G. [PETER III. OF RUSSIA.]

ORMOND, the name of a large territory in the Irish county of Tipperary; and from thence the title of a noble house, so antient and illustrious, that its origin has been, perhaps fancifully, ascribed to the ducal blood of Normandy, before the conquest of England. But it is certain that this family, having become established in Ireland, and distinguished by many services to the crown, as well as by several noble intermarriages, was recognised in that country, from the very beginning of the thirteenth century, as holding the hereditary office of royal cup-bearer or butler: from which, whether then or at an earlier period, their sirname appears to have been derived. Edmund le Botiller was raised by Edward II. to the earldom of Carrick; his son James, who espoused Eleanor Bohun, granddaughter Edward I., was created by Edward III. earl of Ormond; the issue of that marriage, a second James, called, from royal descent, 'the noble earl,' filled the dignity of Justice of Ireland, the government of which kingdom was administered under various titles by several of his descendants.

The distinguished individual however of the race was **JAMES BUTLER, DUKE OF ORMOND**, justly described by his biographer as 'one of the ablest statesmen, most accomplished courtiers, and worthiest persons of the age in which he flourished.' He was born in London in 1610; and, notwithstanding the splendour of family dignities which he was destined to augment, his youth was passed under circumstances sufficiently adverse to have obscured the career of a less energetic spirit. His grandfather, Walter, earl of Ormond, who had succeeded to the title only collaterally, was exposed to the tyranny of James I., and imprisoned for several years, because he refused to submit to an unjust award of that monarch in behalf of one of his Scottish favourites, Sir John Preston, created lord Dingwall, to whom the king had compelled the late earl to marry his daughter, and was now resolved to convey the family estates. The eldest son of Earl Walter married, against his consent, a daughter of Sir John Poyntz; and being drowned in crossing the Irish Channel, during his father's life, left without provision a large family, of which James Butler, the future duke, was the eldest son. When Earl Walter was thrown into prison, his grandson and heir, young James, now styled viscount Thurles, was arbitrarily seized in wardship by the crown, but, with some care for his instruction, committed to the tutelage of archbishop Abbot; the only benefit by which the king may have designed to mitigate his cruel oppression of the family. The archbishop is said to have neglected the general education of his charge; but he caused him to be well instructed in the Protestant faith, to which we have the testimony of Burnet, in other respects not his panegyrist, that he staunchly adhered throughout his life.

On the death of James I., Earl Walter having recovered his own liberty and the guardianship of his heir, then in his sixteenth year, the young Lord Thurles began soon after to figure at court, where he paid his addresses to his kinswoman, Lady Elizabeth Preston, and having engaged her affections, succeeded, not without many difficulties, in obtaining the royal assent to their union. This marriage, which took place in 1629, and seems to have been produced as much by mutual attachment as policy, was however not the less fortunate in reconciling differences which had been fatal to both their families; and, in 1632, Lord Thurles succeeded, on his grandfather's death, to the earldom of Ormond.

It was at this time that Lord Wentworth, more unhappily distinguished under his later title of Strafford, entered on the government of Ireland; and the spirited and honourable deportment of the young earl of Ormond soon attracted so much of his notice as to lead him to prophesy, with characteristic penetration, that 'that young nobleman would make the greatest man of his family.' In subsequent years, the upright and generous devotion of Ormond to the service of the crown and country won the respect even of the overbearing Strafford; and after his own ruin, one of his last requests to his royal master was, that his blue ribbon of the Garter might be bestowed upon his friend Lord Ormond. On the breaking out of the Irish Rebellion of 1640, Ormond was appointed by the lords-justices to the command of the royal troops; and throughout the disastrous period which followed, he continued, amidst the fury and jealousy of factions, embittered both by political and religious hatred, to pursue with unshaken integrity and moderation a course of true patriotism and fidelity to his duty. With very inadequate forces, he repeatedly defeated the rebels, near Dublin, at Drogheda, at Kilrush, and at Ross; but notwithstanding these services, in the course of which he was thanked by the Long Parliament, and raised to the dignity of marquis by the king, he was so ill supported on all sides, that he was unable longer to sustain the unequal conflict in which he had engaged. There were now no fewer than five parties in Ireland:—the Protestants and Roman Catholics well affected to the king, but opposed to each other; the Protestants favourable to the parliamentary cause; the Papists under their priests wholly devoted to the court of Rome; and the Scotch Presbyterians of the north, who had their separate interests and feelings. The exertions of Ormond being paralysed by the dissensions which prevented the majority of these factions from uniting against the common enemy, he was compelled, in 1643, to conclude a treaty for a cessation of arms, which, on account as the previous barbarities committed by the Irish rebels, excited great dissatisfaction in England.

Throughout the next four years, during which the civil war was raging in England, Ormond, who had been invested by Charles I. with the nominal dignity of lord-lieutenant of Ireland, contrived in some measure to hold that kingdom for his master, and even to detach forces to his aid. But when Charles had fallen into the hands of his enemies, the position of the lord-lieutenant in Ireland against the Roman Catholics having become completely untenable, he resigned his authority by treaty into the hands of parliamentary commissioners, and proceeded to render a satisfactory account of his conduct to the king, then a prisoner at Hampton Court. From thence he retired to France; but still directing his attention to Ireland, and receiving encouragement from the portion of the Roman Catholics best affected to the crown, he again landed in that kingdom, and endeavoured to restore the royal authority. Notwithstanding every gallant effort however, he was defeated in an attempt to besiege the parliamentary forces under Colonel Jones in Dublin; and Cromwell himself soon after landing in Ireland with an overwhelming force, Ormond was finally obliged, at the end of the year 1650, to evacuate the island and withdraw to France. From this time until the death of Cromwell, during which interval he was frequently reduced to great straits for the common necessaries of life, Ormond was actively and variously employed in many important and dangerous missions for his exiled king, Charles II.; and, on the Restoration, he accompanied Charles to England, and was rewarded for his sufferings and services by his elevation to the ducal title and other honours.

The remainder of the life of the duke of Ormond was passed, though not without some troubles and reverses, in the dignified enjoyment of a high rank and spotless reputation. These could not always protect him from the royal caprice and the base machinations of court intriguers; and during the reigns of Charles II. and James II., he was twice again possessed and deprived of the government of Ireland, which he administered for many years with admirable integrity, wisdom, and justice. It was in the interval of his long tenure of this high office, that, in 1670, a singular and atrocious outrage was committed upon his person in the streets of London by that notorious ruffian Colonel Blood, who, with five accomplices, waylaid him as he was returning from a state dinner in the city, and dragged him from his coach, with the intention, as it was believed, if he had not been rescued, of hanging him at Tyburn. Blood, who had been engaged in a plot to seize the castle of Dublin during Ormond's government of Ireland, pretended that he was resolved to retaliate upon the duke's person for the execution of some of his associates on that occasion; but it was strongly suspected that the villain had been instigated to his audacious attempt by the profligate duke of Buckingham, the bitter enemy of Ormond; and so convinced was his gallant son, the earl of Ossory, of the guilt of Buckingham, that, soon after, at court, seeing that nobleman standing by the king, he said to him, 'My lord of Buckingham, I know well that you are at the bottom of this late attempt of Blood's upon my father; and therefore I give you fair warning, that if my father comes to a violent end by sword or pistol, if he dies by the hand of a ruffian, or by the more secret way of poison, I shall not be at a loss to know the first author of it. I shall consider you as the assassin; I shall treat you as such; and wherever I meet you, I shall pistol you, though you should stand behind the king's chair. And I tell it you now in his Majesty's presence, that you may be sure I shall keep my word.'

Ormond himself was remarkable for some pithy sayings. When he was ungratefully abandoned to the malice of his enemies by Charles II. in his first government of Ireland after the Restoration, he contented himself with saying to the king, that 'though it would never trouble him to be undone for his Majesty, yet it would be an insupportable affliction to be undone by him.' And when Blood had been made prisoner in his attempt to seize the regalia, and Charles, strangely infatuated, if not disgracefully intimidated by the language of the ruffian, whom curiosity led him to visit in the Tower, sent to Ormond to desire that he would forgive Blood, for reasons which Lord Arlington would tell him, the duke drily replied to that nobleman, 'that if the king could forgive the offender for stealing the crown, he might easily forgive the attempt upon his life; and that if such was his Majesty's pleasure, that was for him a sufficient reason, and his lordship might spare the rest.' Ormond lived unmolested for many years after this flagitious attempt, though he had the misfortune to survive the noble-minded Ossory; and he himself died, full of years and honour, in the year 1688.

Of his numerous children, the eldest who grew to manhood was Thomas, earl of Ossory, the worthy son of such a father, and eulogized by Burnet as 'a man of great honour, generosity, and courage.' He was also gifted with many intellectual accomplishments; was equally distinguished throughout the reign of Charles II. for his military services by sea and land; and would probably, if his life had been spared, have proved himself even a more perfect character than his parent: but he died of a violent fever in 1680, at the premature age of forty-six years. He was the father of James, second duke of Ormond, who inherited several of the generous and chivalric qualities of his house, and took a conspicuous share both in the military achievements and civil dissensions of the reigns of William III. and Queen Anne. But when driven from England on the accession of George I., by the persecution of his political antagonists, he embraced the cause of the Pretender; and being consequently attainted, he sullied his fame by engaging in the service of the natural enemies of his country, and accepting from the king of Spain the command of an abortive expedition for the invasion of Great Britain.

ORMSKIRK. [LANCASHIRE.]

ORMUS, or more properly **HORMUZ**, is an island at the entrance of the Persian Gulf, near 27° N. lat. and 56° 30′ E. long. It is about ten miles from the Persian coast, and about twelve miles in circumference. Its form is nearly circular, and its appearance from the sea is broken and rugged. It is a mere barren rock, without vegetation. The surface, which is entirely without soil, exhibits the singular stratification of the island; the conical shape and isolated position of the numerous small hills of which the island consists, lead the spectator to attribute its origin to volcanic agency. The rugged hills which line the eastern shores of the island are covered for a considerable distance from their base with an incrustation of salt, which in some places is as transparent as ice. In other places the surface is covered with a thin layer of dusky red-coloured earth, which owes its colour to the oxide of iron, with which the whole surface of the island is impregnated. Even the sand on the sea-shore is composed of the finest particles of iron, pulverised by the waves. As the island contains no fresh-water springs, the inhabitants use the rain-water collected in several tanks, which were constructed perhaps some 300 years ago. There is excellent anchorage on the north-eastern shore, opposite the town, where a vessel may be sheltered from all winds within half a mile of the shore. The fortress is situated about 300 yards from the shore, on a projecting point of land, which is separated from the island by a moat. On the plain which stretches from it to the hills, and is about two miles wide, are the ruins of the once-famous town of Hormuz. The Imam of Muskat has now possession of the island; he farms it from the king of Persia, and has a garrison of 100 men in the fortress. He derives a revenue from the salt, which is exported in large quantities. In 1827, the number of inhabitants was estimated at 300, all of whom were employed in collecting salt or in fishing.

The name of Harmozia occurs in Arrian's 'Indica,' where however it does not denote the island, but a town situated opposite to it on the continent of Persia, on the river Anamis, now called Minaw. The name was afterwards transferred to the island, which, according to Ouseley, was previously called Jerûn. In antient times it seems only to have served as a place of retreat to the inhabitants of the adjacent shores in times of invasion or civil commotion. Albuquerque took possession of the island in 1507, and of the town, which was then on it, with the view of preventing the Arabs who inhabited the shores of the Gulf from sending aid to the petty sovereigns on the coast of Malabar, with whom they carried on a lucrative commerce. The consequences of this event were much more favourable to the Portuguese than Albuquerque had imagined. The inhabitants of the shores of the Persian Gulf finding that their commerce with Hindustan was entirely cut off, the Portuguese made Ormus the deposit of all kinds of Indian goods, and managed their affairs so well, that in a short time Ormuz became a populous and rich commercial town. The buildings covered a space three miles in length along the sea-shore, and two miles in width. The town contained 4000 houses and 40,000 inhabitants, and its commercial relations extended over all Persia and Mesopotamia to Bokhara and Samarkand in Turkistan. The loss of Ormuz was one of the first signs of the decline of the Portuguese power in India. In 1622, Shah Abbás the Great took it from them, in which enterprise he was assisted by the English with a squadron of nine sail of the line. He expelled the Portuguese, demolished the town, and transferred its commerce to Gombroon, or Bunder Abbas, on the mainland of Persia, nearly opposite to Ormus. Gombroon continued to be the principal commercial town on the Gulf of Persia until the middle of the last century, when Aboushehr took its place.

(Ouseley's *Travels in various Countries in the East, &c.*; Kinneir's *Geographical Memoir;* Kempthorne 'On the Eastern Shores of the Persian Gulf,' in *London Geographical Journal*, vol. v.; and Whitelock 'On the Islands and Coast at the Entrance of the Gulf of Persia,' in *London Geographical Journal*, vol. viii.)

ORNE, a department in the northern part of France, bounded on the north by the department of Calvados, on the north-east by that of Eure, on the east and south-east by that of Eure et Loir, on the south by those of Sarthe and Mayenne, and on the west by that of Manche. The department has an irregular oblong figure; the greatest dimension is from east to west, from the neighbourhood of Longny to that of Passais near Domfront, 84 miles; the greatest breadth from north to south is from near La Ferté Frenel to the contact of the three departments of Orne, Sarthe, and Eure et Loir, 50 miles. It is comprehended between 48° 10′ and 48° 57′ N. lat., and 0° 59′ E. and 0° 52′ W. long. The area of the department is estimated at 2364 square miles, being very little less than the average area of the French departments, and rather exceeding the conjoint areas of the English counties of Kent and Surrey. The population, in 1831, was 441,881; in 1836 it was 443,688, showing an increase in five years of 1807, or less than half per cent., and giving 183 or 184 inhabitants to a square mile. In amount of population it is inferior to either of the above-mentioned English counties, and in density of population very far below them. Alençon, the capital, is 105 miles in a direct line west-south-west of Paris, or 115 miles by the road through Versailles, Dreux, and Mortagne.

The department is traversed in the direction of its length by the mountains which form the prolongation of the Armorican chain, and which separate the basin of the Loire from the basins of the Seine and the various small rivers that flow into the English Channel. The western side of the department is occupied by the primitive and other rocks which underlie the coal-measures. Coal is not found, at least not worked. The valleys of the Sarthe and Orne are chiefly occupied by the formations which intervene between the chalk and the new red-sandstone; and the eastern side of the department is overspread by the chalk which encircles the Paris basin. Mines of iron and manganese are worked in several places: gold was once found, but the working of the mine has been long given up. Granite of a fine grain, limestone, freestone, white and grey marl, kaolin for porcelain and clay for earthenware, sand of various kinds suited for glass-works, and the crystals of quartz known as the Alençon diamonds, are dug. There are several medicinal springs, the most important of which are those of Bagnoles near Juvigny, in the arrondissement of Domfront. There are twelve iron-works in the department, in which are ten furnaces for smelting pig-iron, and thirty forges for producing wrought-iron. Charcoal is almost exclusively employed as fuel in these works.

There are no navigable rivers in the department. The Mayenne has its source and some part of its course just within the southern border; and the Vée, the Varenne (with its feeder the Egrame), and the Sarthe, tributaries of the Mayenne, also rise in the department, in or upon the border of which the Sarthe has the first 35 miles of its course. The Huine, a tributary of the Sarthe, and the Commeauche and the Meme, feeders of the Huine, rise in this department, and water its eastern part. The Mayenne and its tributaries belong to the system of the Loire. The Eure, he Iton, the Rille, the Charentonne, and the Gruil, all which belong to the system of the Seine, rise on the eastern side of the department. The Orne rises near Séez, and flows nearly 40 miles before it quits the department: its tributaries, the Thouane, the Ure, the Cance, the Udon, the Rouvre, and the Noireau, and the Vere, a feeder of the Noireau, belong to this department. The Dives and the Toucques, with its feeder the Vie, rise in the department. The Orne, the Dives, and the Toucques flow into the English Channel. There are no navigable canals, and the department is entirely destitute of internal navigation.

There are eight Routes Royales, or government roads, having an aggregate length of 204 miles, viz. 85 in good repair, 113 out of repair, and 6 unfinished. The principal road is that from Paris to Rennes and Brest, which enters the department on the east side, and passes through Tourouvre, Mortagne, Le Mêle, and Alençon, about 12 miles beyond which it quits the department. Roads lead from Alençon in one direction to Le Mans, in the department of Sarthe; in another, by Séez and Gacé to Rouen, in the department of Seine Inférieure, with a branch from it at Séez by Argentan to Falaise and Caen, in the department of Calvados. A road from Caen to Mayenne and Laval (Mayenne) passes through Flers and Domfront, in the western side of the department; and a road from Paris to Alençon by Chartres and Nogent-le-Rotrou (Eure et Loir) passes through Bellême in the south-eastern corner. The Routes Départementales, or departmental roads, have an aggregate length of 294 miles, viz. 183 in repair, 6 out of repair, and 105 unfinished. The bye-roads and paths have an aggregate length of above 4500 miles.

The climate is temperate: westerly winds are predominant, and bring with them mists and rain. Agriculture is in a backward condition, the cultivators clinging to old usages with considerable tenacity. The whole surface of the department is estimated at more than 1,500,000 acres, of which about 800,000 acres, or above half, are under the plough. The principal grain cultivated is oats, the produce of which exceeds the average produce of France in the proportion of 4 to 1. In wheat and barley the produce is below the average of France, in rye and maslin, or mixed corn, considerably below, and in potatoes still more so; but in buckwheat the preponderance is proportionately almost as great as in oats. About 25,000 acres are occupied as orchards and gardens: the growth of apples for cider is very great, though perhaps not equal to what it was before the Revolution. As no wine is grown, cider is the common drink, and in abundant years a portion of it is distilled into brandy. Pulse, hemp, and flax are raised; plums are grown in considerable quantity; and some beet-root for the manufacture of sugar. There are about 300,000 acres of meadow land, and heaths and open pasture-grounds to the extent of 45,000 acres. The meadows, especially in the valleys of the Toucques and the Vie, produce abundance of grass, and furnish food for the horses and horned cattle, in the number of which this department is pre-eminent. The horses are of the best Norman breed, and the horned cattle are generally of good breed. The butter and cheese, except the cheese of Vimoutiers, which is in good repute, are of inferior quality. The oxen for fattening are brought from the departments of La Vendée, Deux Sèvres, and Mayenne: the finest beasts are sent to Poissy (Seine et Oise) for the supply of Paris. The number of sheep rather exceeds the average of France, but the breed and management have been very much neglected: folding them is little practised. The introduction of the Merinos and the crossing of the breed with them have led to some improvements. Swine are numerous, and are almost entirely destined for the supply of Paris. In the arrondissement of Argentan, poultry, especially geese, are much attended to, and their flesh and their quills and feathers form important articles of produce. Bees are kept. There are about 180,000 acres of woodland. Small game are tolerably abundant; the partridges of Domfront are in high repute. The rivers abound with fish.

The department is divided into four arrondissements as follows:—

		Sq. Miles.	Population. 1831.	1836.	Communes.
Alençon	S.	400	73,198	72,443	95
Argentan	N.	723	113,955	113,233	190
Domfront	W.	482	128,948	131,745	94
Mortagne	E.	759	125,780	126,267	155
		2364	441,881	443,688	534

There are thirty-six cantons or districts, each under a justice of the peace.

The arrondissement of Alençon contains the towns of Alençon (population, in 1831, 13,548 for the town itself, or 14,019 for the whole commune; in 1836, 13,934 for the commune) [ALENÇON] and Le Mêle, on the Sarthe; Séez (population 3672 for the town, 5059 for the whole commune), on the Orne; Carrouges, on the Udon, a feeder of the Orne; and Essey, between Le Mêle and Séez. Séez, probably the capital of the Saii, an antient Celtic people, was of more importance in the ninth century (when it was destroyed by the Normans) than it is at present. In the subsequent centuries it suffered severely in the wars of France with the dukes of Normandie and the English. Its principal edifice is the cathedral, a Gothic building of the twelfth century, adorned with sculptures and paintings. The townsmen are engaged in the manufacture of embroidered muslin and other cotton goods. There are a college and an agricultural society. Charlotte Corday was born at Séez. Le Mêle is a tolerably handsome town of one street along the road from Paris to Alençon and Rennes. The inhabitants amount to about 1800. At Carrouges the manufacture of an embroidered muslin is carried on.

In the arrondissement of Argentan are—Argentan (population, in 1831, 5812 for the town, or 6147 for the whole commune; in 1836, 5772 for the commune) [ARGENTAN] and Ecouché, on the Orne; Grand Mesnil, on the Thouane, a feeder of the Orne; Briouze, near the Rouvre, another feeder of the Orne; Rânes, between the Thouane and the Rouvre; Exmes, Chambois, and Trun, on the Dives; Vimoutiers, on the Vie; Merlerault, Gacé, and Le Sap, on or near the Touques; and Echauffou, St. Evroult, and La Ferté Fresnel, on or near the Charentonne. Vimoutiers is the centre of a district in which 20,000 persons are engaged in the manufacture of stout bleached linens. There are several tanyards in the town, which has a population of about 3500. The village of Sainte Honorine de Guillaume, west of Argentan, has a population of 2000, who are engaged in quarrying and working granite; and at Le Pin, near Argentan, is an extensive establishment for improving the breed of horses. Before the Revolution, this establishment was maintained in great extent and completeness, and persons resorted to it from all parts of France, and from England, Spain, Germany, and Italy, to purchase saddle-horses or hunters. It was suppressed in the early period of the Revolution, but its suppression led to a great degeneracy in the horses of Normandie, and it was re-established during the consular government.

In the arrondissement of Domfront are—Domfront (population, in 1831, 1511 for the town, or 1873 for the whole commune; in 1836, 2417 for the commune) and St. Gervais, on the Varenne; Lonlay, on the Egrenne; Flers (population 1640 town, 4262 whole commune), on a branch of the Vere; Tinchebray (population 3254 town, 3413 whole commune), on the Noireau; La Carneille, near the Rouvre; Couterne and Juvigny-sous-Andaine, on or near the Mayenne; and La Ferté Macé (population 2192 town, 4413 whole commune), on a branch of the same river. Domfront is situated on the summit of a steep rock, through a cleft in which, 300 feet deep, the river Varenne flows. The townsmen manufacture coarse linens and other woven goods. At Flers and La Ferté Macé cotton goods are woven, and at the latter box-wood snuff-boxes are made. There are iron-works and paper-mills at Tinchebray, which has some historical interest as the scene of the battle which transferred the duchy of Normandie from Robert, eldest son of William the Conqueror, to his younger brother and competitor Henry I. of England.

In the arrondissement of Mortagne are—Mortagne (population, in 1831, 4742 town, 5150 whole commune; in 1836, 5171 commune), near the head of the Commeauche; Tourouvre, near the bank of the same river, and Longny on one of its feeders; Mauves and Rémalard or Regmalard, on the Huisne; Bellême (population 3384 town, 3413 whole commune), on the Même, a feeder of the Huisne; Moulins-la-Marche, near the head of the Sarthe; and L'Aigle (population 4712 town, 5410 whole commune), on the Rille. Mortagne is on the summit and the eastern slope of a hill, the height of which has been estimated (but probably with exaggeration) at 1000 feet. It is walled, and entered by five gates, adjacent to which are as many suburbs. The principal street is of considerable length and of a good width; it runs along the road from Paris to Brest, and near its western end is the parade, the principal open space in the town. Mortagne is the residence of many genteel families, and abounds with mansions and good houses, which, together with the length and width of its principal street, lead travellers to think it of greater extent and importance than it really is. The numerous shops are well furnished, and with articles of luxury or convenience not commonly kept in towns of the same size; with these articles it supplies places larger than itself. The great want of the town is of water. It is supplied from fountains at the foot of the hill, from whence the water is carried and sold to the inhabitants. The principal church is in a commanding situation; it is of Gothic architecture, and its massive tower, surmounted with 'a quadrangular dome,' forms a striking object at a distance. There is an hospital or almshouse, with a pleasant garden attached; but has not (unless lately established) either a theatre or public walk. There are some linen and cotton manufactures; the linens are suited for exportation to the colonies. There are two weekly markets, and several yearly fairs, two of them considerable horse-fairs. Mortagne was anciently the capital of the province of Le Perche, and a place of strength; it suffered much in several wars, and in the war of the League was pillaged by one party or the other twenty-two times in less than four years. A few miles from Mortagne is a Trappist convent, re-established with additional austerities since the restoration of the Bourbons. At Tourouvre, which has about 1500 to 2000 inhabitants, are iron and glass works; at Longny, which has about 2500 to 3000 inhabitants, there are iron-works, and trade is carried on in cattle and horses. Rémalard or Regmalard, with about 1700 inhabitants, is pleasantly situated, and is the seat of a small trade in hemp and hides. Bellême is on a hill; it consists of one principal street along the road from Chartres and Nogent to Alençon. It was formerly a place of strength, and sustained several sieges. The inhabitants manufacture some table and other linens, cotton goods, and paper; and trade in agricultural produce, and in wood obtained from the forest of Bellême, one of the best in France for the fine trees which it produces, though not of great extent. At Moulins-la-Marche fire-arms are manufactured. L'Aigle is pleasantly situated on the slope of two hills, and is surrounded by walls and a ditch. It is probably the busiest manufacturing town in the department. The pins and knitting and sewing needles made here are known all over France; and a great quantity of curtain-rings, iron, steel, steel and copper wire, wires for pianos, and other small hardwares are made. Stockings, hats, laces, tapes, woollen and linen fabrics, leather, and paper are also manufactured. There are five yearly fairs.

The population of the towns, when accurately given, is from the census of 1831; and, when not otherwise specified, is that of the whole commune; when given approximately, it is from Dulaure's *Environs de Paris* (A.D. 1828), or Vaysse de Villiers's *Itinéraire Descriptif* (1821-1829).

The principal manufactures in the department are those of iron and hardwares in the arrondissements of Mortagne and Argentan; lace, linens, and cottons in those of Alençon and Domfront; haircloth, pottery, glass, paper, and leather. Many of the inhabitants resort every year to the neighbouring departments to follow their business as stone-cutters, hemp-combers, gardeners, hawkers of haircloth, &c. This custom of migration has diminished since the Revolution.

The department constitutes the diocese of Séez, the bishop of which is a suffragan of the archbishop of Rouen. It is in the jurisdiction of the Cour Royale and the Académie Universitaire of Caen; and in the fourteenth military division, of which Rouen is the head-quarters. It returns seven members to the Chamber of Deputies. In respect of education it is above the average of France; of the young men enrolled in the military census of 1828-29, 45 in every 100 could read and write.

At the time of the Roman conquest this part of France was included chiefly in the territory of the Saii (who were probably the Essui of Cæsar), but portions of it appear to have been included in the respective territories of the Baiocasses, the Viducasses, the Lexovii, the Aulerci-Eburovices, the Carnutes, the Aulerci-Cenomani, and the Diablintes. These were all Celtic nations, and were comprehended in the Roman province of Lugdunensis Secunda, except the last three, who were included, the Aulerci-Cenomani and the Diablintes in Lugdunensis Tertia, and the Carnutes in Lugdunensis Quarta. The only antient town known in have existed within its boundary was Saii, now Séez. Some Roman antiquities have been found; among them are some inscriptions near a mineral spring in the forest of Bellême. In the middle ages this district constituted Le Pays d'Houlme and La Campagne d'Alençon; it also formed part of Les Pays de la Campagne, d'Ouche, de Lieuvin, and de Boccage, all in Normandie. The arrondissement of Montagne formed part of the county of Perche. The country suffered much from the wars of the Normans and the English in France, and from the religious wars of the sixteenth century.

ORNITHICHNITES, Professor Hitchcock's name for the footmarks of birds impressed on the surface of sandstone in the valley of the Connecticut. [GRALLATORES, vol. xi., p. 345.] The following will be read with interest as being connected with this subject:—

In a paper read before the Geological Society of London on the 15th May, 1835, Dr. Mantell stated that soon after his attention was directed to the fossils of the Wealden, he discovered in the strata of Tilgate Forest several slender bones, which, from their close resemblance to the tarso-metatarsal bones of certain *Grallæ*, or *Waders*, he was induced to refer to Birds. The correctness of this opinion was afterwards doubted, in consequence of the so-called bones of birds found at Stonesfield being ascertained to be the osseous remains of Pterodactyles. Subsequently however Dr. Mantell discovered specimens of a more decided character, and submitted them to Baron Cuvier during his last visit to England; and that distinguished zoologist pronounced them to have belonged to a Wader, probably a species of *Ardea*. Doubts were, notwithstanding, still entertained, not only whether these remains did really belong to any of the *Ardeidæ*, but whether they were referrible to Birds at all. The specimens having been placed by Dr. Mantell in the hands of Professor Owen, that acute comparative anatomist pointed out one bone as having undoubtedly belonged to a Wader. This fossil he declared to be the distal extremity of a left tarso-metatarsal bone, and it presented the articular surface, or place of attachment, of the posterior or opposable toe. Other specimens of long bones were conceived by the professor to have belonged to a more erpetoid form of bird than is now known.

This examination confirms Dr. Mantell's previous views of the existence of the remains of birds below the chalk, and the fossils described by him are the oldest *remains* of the class at present discovered. (*Geol. Proc.*, vol. ii.; *Geol. Trans.*, vol. v., 2nd series.)

ORNITHOCE'PHALUS, Sömmering's name for the extinct Saurian form termed *Pteroductylus* by Cuvier. [PTERODACTYLE.]

ORNITHO'LOGY, the science which teaches the natural history and arrangement of birds. The term is derived from the Greek words Ὄρνις, 'ornis,' a bird, and λόγος, 'logos,' a discourse; signifying literally 'a discourse upon birds.' [BIRDS.]

ORNI'THOPUS, is a genus of small papilionaceous annual plants, found in pastures and wild places in Europe. They are characterised, among other things, by a cluster of curved pods which are jointed something like a bird's toe, on which account they are called bird's-foot trefoil. The species found in this country is a plant from two to six inches high, with pinnated leaves and small white flowers striped with red, and is of no economical importance; but in Portugal occurs the *O. sativus*, an annual growing as much as two or three feet high, with stems as succulent and nutritious as those of vetches or lucerne, and cultivated in that country as food for cattle under the name of *Serradilla*. It succeeds in blowing sand, and is capable of yielding an abundant produce in the poorest soils. The writer of this note formerly saw it grown to some extent in the sandy land about Thetford, and the crop of herbage at that time was most abundant; it does not however seem to have been introduced into general cultivation.

ORNITHORHYNCHUS, Blumenbach's name for that extraordinary quadrupedal form, *The Duckbill*, or *Duckbilled Platypus*, *Platypus anatinus* of Shaw; *Mallangong*, *Tambreet*, and (according to the French) *Mouflengong* of the natives of New South Wales; *Water-mole* of the English olonists.

It is hardly to be wondered at that when this animal was first sent from New Holland to this country, it was received by zoologists with caution amounting to suspicion. The ingular beak, which occupied the usual place of the mouth, startled the observer when it appeared as the organ of a hairy quadruped; nor was it till one or two more specimens arrived (from Governor Hunter, we believe, and addressed to Sir Joseph Banks) that naturalists were ready to allow that this beak was naturally attached to the body.

Upon a form so anormal conjecture was busy, more especially as to that part of its organization relating to reproduction. Was it oviparous or viviparous? Did it suckle its young? These were questions constantly asked, and answered as such questions generally will be, in the absence of autopsy and direct experiment, with considerable tact and learning by the supporters of the different theories, but with no satisfactory result. Evidence however gradually came in, and fortunately fell into the hands of those capable of using it; and we now know, principally by the enlightened labours of Professor Owen, that the *Ornithorhynchus* is an ovoviviparous animal, that it suckles its young, and that its proper place is among the *Monotremata*, or Monotremes, a group to which no animal hitherto discovered belongs, excepting that which forms the subject of this article and *Echidna*. [ECHIDNA; MONOTREMES.]

Both these forms appear to have been first presented to the public by Dr. Shaw:—*Echidna* under the appellation of *Myrmecophaga aculeata*; and the Duck-billed animal under the name of *Platypus anatinus*. This was at the close of the eighteenth century: at the commencement of the present, Blumenbach described the latter form more at large under the title of *Ornithorhynchus*; and Mr. Home (afterwards Sir Everard) gave an account of some anatomical peculiarities connected with the head and beak, in *Phil. Trans.* (1800). Sir Everard's subsequent papers on the anatomy of *Echidna* and *Ornithorhynchus* (*Phil. Trans.*, 1802) went more at large into the subject, and disclosed numerous affinities between two forms differing much in external appearance. He therefore grouped them both under the same generic name; and at the same time expressed his opinion that the generative process differed considerably from that of the true *Mammalia*, resting that opinion on the peculiarities of the organs destined for reproduction, and on the absence of nipples in both species, especially in the female *Ornithorhynchus*.

Geoffroy St. Hilaire was not tardy in adopting the opinion of Sir Everard. He constituted a new order for these strange forms, and a hasty dissection having led him to conclude that the genital products of *both sexes*, as well as the urine and fæces, had their issue by a common outlet, he gave to that order the name of *Monotremes*. His inferences were, that both mammary glands and nipples were wanting, and certain accounts of the discovery of eggs of the *Ornithorhynchus*,* strengthening his belief in the oviparous character of the *Monotremes*, he separated that order from the *Mammalia*.

A penetrating mind like Cuvier's could hardly fail of being particularly attracted by these anomalous forms. The *Myrmecophaga aculeata* of Shaw was soon removed by the great and acute French zoologist from the true *Ant-eaters* (among which its first describers, deceived by external appearances, had placed it), and separated under the name of *Echidna*, by which it is still known. Following out the anatomy of that form as well as of *Ornithorhynchus*, he saw their mutual relations, and adopted Geoffroy's group and name, but did not exclude the tribe or family from the *Mammalia*.

The opinions of Geoffroy were strenuously opposed by Oken and De Blainville. The former even conjectured that the mammary glands would be found in the *cloaca*. The latter, in a learned dissertation upon the place which *Echidna* and *Ornithorhynchus* ought to occupy in the system, expressed his confidence that the mammary glands would be ultimately detected, and his opinion that the animals themselves approached closely to the *Marsupialia*.

We now arrive at a period when the thick darkness which overshadowed this interesting subject began to be dispelled by the light derived from a further supply of subjects and consequent anatomical investigation. Professor Meckel (1824, 1826) determined the existence of the mammary glands, and showed, particularly in his work of the latter date (Monograph on *Ornithorhynchus paradoxus*), that they were largely developed in the female. Their situation, size, form, and lobular composition are accurately described. He was not able to inject the gland, and did not accurately know the exact termination of the ducts, but he noticed certain small eminences in the middle of the areola, and announced that they were without doubt the orifices of those ducts. So far Meckel satisfactorily proved the relationship of the *Ornithorhynchus* to the *Mammalia* in general, but his reasoning led him to conclusions not consonant to the identity of their mode of reproduction. He argued that the difference between the production of living young and of eggs is in reality very small and not essential, that birds have occasionally hatched the eggs within the body, and, in effect, given birth to a living chick; concluding that as the generation of the *Marsupialia* closely resembles the oviparous mode, it is highly probable that the method of generation of the *Ornithorhynchus*, which approaches still nearer to birds and reptiles, might be analogous in proportion.

---

* Letter of Mr. Hill, 'Linn. Trans.' vol. xiii.; *Mém. du Mus.*, tom. xv.; and of Professor Grant, *Ann. des Sc. Nat.*, tom. xviii.

The close and authentic demonstrations of Meckel were not sufficient however to dispel the doubts which still hung over the subject in the minds of some. It is hard to some natures to give up preconceived opinions, and M. Geoffroy St. Hilaire, who had subsequently dissected a female *Ornithorhynchus*, stoutly combated* the evidences adduced by Meckel of the mammiferous nature of the animal, and brought the whole of his acumen to bear on the inferences of the latter, in his attempt to invalidate them. He denied that the subcutaneous glands pointed out by Meckel were mammary, urging that they had none of the characters of a true mammary gland—that he had compared them with the same parts in the human subject and in the Marsupials, and that their texture was totally different—that they consisted of a multitude of cæcums placed side by side, and all directed to the same point of the skin, where were to be seen only two excretory orifices, and these so small that the head of the least pin would not enter them, and that there was no trace of nipples. He further stated that in the individual examined by him, which had the appearance and proportions of an adult female, the gland was not more than one-fourth as large as in Meckel's specimen, observing that when a mammary gland is fully developed, an enlargement of all its constituent parts is effected, and the nipple acquires additional size even before the commencement of lactation, and remarking that no such appearance has been noticed in *Ornithorhynchus*. Professor Geoffroy, having thus denied the inferences of Professor Meckel, had to account for the use of these glands, and he considered them as analogous to the glands upon the flanks of aquatic reptiles and fishes destined to secrete a lubricating fluid, or to the odoriferous follicles of hairy quadrupeds, more especially those on the sides of the abdomen in the Shrews.

To these assertions Professor Meckel replied, and was supported by Professor Von Baer.

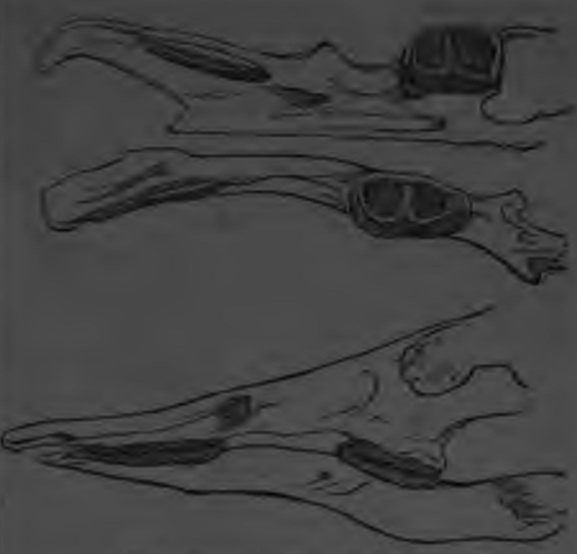
We now arrive at the highly interesting papers of Professor Owen, which may be considered as having settled this much agitated question. The first of these, 'On the mammary glands of the *Ornithorhynchus paradoxus*,' was read before the Royal Society (21st June, 1832), and is published in 'Phil. Trans.' for 1832, part ii.; the second, 'On the ova of the *Ornithorhynchus paradoxus*,' was read before the same Society on the 19th June, 1834, and is published in 'Phil. Trans.' for 1834, part ii.; and the third, 'On the young of the *Ornithorhynchus paradoxus*,' was communicated to the Zoological Society of London, on the 27th May, 1834, and is published in the first volume of the 'Transactions' of that Society. We say no more of these excellent memoirs here, as we shall presently have occasion largely to draw upon them.

ORGANIZATION.

The dental formula of Ornithorhynchus may thus be stated:—molars, $\frac{2-2}{2-2}=8$.

It is to be borne in mind that these organs are not true teeth; their structure will be explained under the section which treats of the *digestive organs*; but as they perform, as far as their conformation will allow, the offices of teeth, and are placed in the situation usually allotted to the *molares* in Mammals, the expression 'dental formula' is not inapplicable.

Skeleton.—The *cranium*, though widely differing from that of other mammals, approaches more closely to the general type of that class, as Cuvier observes, than to any other. It is rounded, wider than it is high, and without either sagittal or occipital crest. It is narrowed and flattened between the orbits, which are small and directed upwards. The muzzle afterwards becomes flattened and widened again, and presents on each side a small hook or process above the suborbital hole; it then becomes bifurcate, and its two flattened and slightly-divaricating branches terminate each by an involute kind of hook. The zygomatic arches are rectilineal and high vertically, and at their upper border is a marked post-orbitary apophysis. Under their anterior base the maxillary bone forms a nearly horizontal flattened surface, to which the two molars adhere. Their posterior base above the glenoid facet is pierced with a hole which communicates from the temple to the occiput. The entire palate is plain, and is continued (narrowing suddenly behind the molars) to the oval holes; up to this point the septum of the nostrils remains bony. The tympanic cavities are very small, and hidden as it were under the mastoid apophysis in the form of a small crest. Cuvier could only detect in his specimens two clear sutures; that which divides the anterior hooks, and that which separates the maxillary from the palatine bones. The position, the implantation of the teeth, and the passage of the suborbital canal well define the maxillary bone. The hook-like bones, which are as it were set in them anteriorly, appear to be the intermaxillary bones. Between them there is suspended, in the midst of the cartilages of the upper mandibles, a small bone, which has an upper plane divided into two by a furrow, a lower plane notched on each side, and a vertical plane uniting the two others. In the neighbourhood of this bone the nostrils are pierced, and it may be taken to represent the nasal bones and the palatine portion of the intermaxillary bones. In the anterior angle of the orbit is a very small lachrymal and a large suborbital hole. This last gives origin to a canal which opens in front of the small hook on the side of the muzzle; it is divided into two by the lateral cartilage of the beak. There comes besides from this canal a hole which opens in the palate under the preceding, and another which, after having formed a long canal, opens at the side of the intermaxillary bone, and consequently in the edge of the osseous beak. Between the first of these three suborbital holes, a little higher, is a small hole which communicates with the aperture of the orbit, pierced in front of the optic, and which Cuvier believes to be analogous to the anterior orbital hole. The first he thinks answers the supraorbital hole in man. The single hole analogous to the spheno and pterygo-palatine is pierced in the lower part of the orbit, a little behind the suborbital canal. It enters also in the nasal canal and in the palate near the first molar. The optic hole is very large and the spheno-orbital equals it; the oval hole is very large and distinct. Between the two oval holes are two membranous spaces. There are behind two very large holes at the place of the condyloidians, but Cuvier supposes that they comprise also the jugulars. Internally the inequalities are but little marked. The *sella*, which is but little elevated, is hollowed out in the middle by a longitudinal canal, and terminated backwards



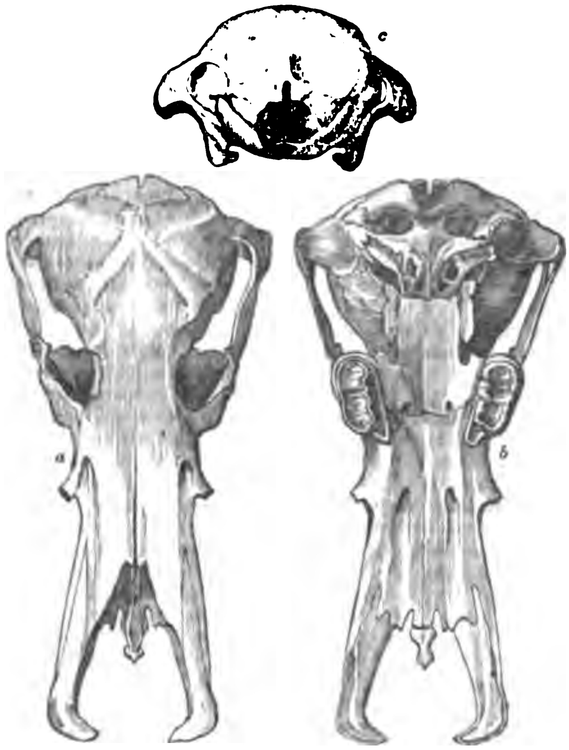
Teeth of Ornithorhynchus. (F. Cuvier.)

---

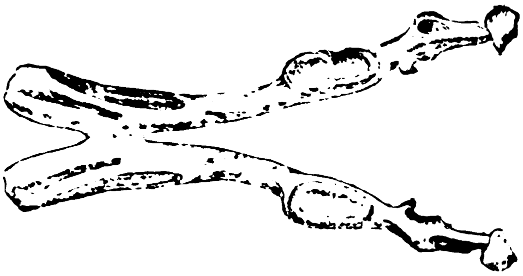
* Ann. des Sc. Nat. [illegible]

by a clinoid and very elevated lamina. The most curious internal part is the ethmoidal fosset, which is small and has only a single hole of no great size for the olfactory nerve, and perhaps another very small one; on each side are spaces, purely membranous, to separate it from the canal of the suborbital nerve. The three semicircular canals project far inwards and intercept a very remarkable hollow. Here may be traced many characters in which the skull of the *Ornithorhynchus* approaches those of birds. The bony *tentorium* is scarcely perceptible, but there is—and this is very remarkable—a large longitudinal osseous *falx*.

In the museum of the Royal College of Surgeons (*Physiological Series*, No. 1546, A) is a longitudinal section of the head, showing the bony *septum narium*, and some filaments of the olfactory nerve descending upon it; also the external nostril, the long nasal passage, with its anterior communication with the mouth by the *foramen incisivum*, and its posterior aperture beneath the *basis cranii*. In the cavity of the cranium may be observed the bony *falx*. (*Cat.*, vol. iii., part i.)

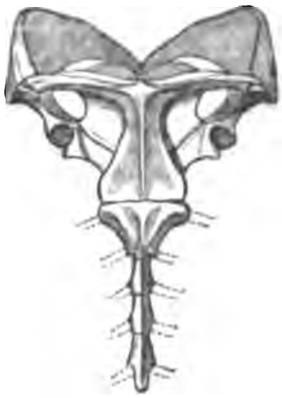


Skull of Ornithorhynchus.
a, seen from above; *b*, seen from below *c*, seen from behind.



Lower jaw of Ornithorhynchus, seen from above.

Anterior Extremities.—In both of the *Monotremes* the most remarkable part of their osteology is perhaps the shoulder, which answers to that of *Birds*, and still more to that of certain *Lizards*. The external surface of the *scapula* is concave, so that it is far from adapting itself to the ribs. Its form and relative position will be better explained by the cuts than by words. The whole of what may be termed the sternal apparatus appears to be formed more after the model of the Saurians than after that of the Mammals: deed it very much resembles that of the *Ichthyosaurus* THYOSAURUS, vol. xii., p. 431], and, like it, is admirably pted for an animal destined to collect its food at the om of lakes and rivers, and requiring machinery to enable it to rise continually to the surface for a supply of air.



Sternal apparatus of Ornithorhynchus two-thirds of the natural size.*

The bones of the arm and forearm, &c. have nothing so remarkable about them as to require particular description, especially as their conformation and relative position will be seen below; but it is deserving of notice that the *carpus* reminds the observer of the same part in the *Carnivora*. The number of the phalanges is the same as in the other mammals, two for the thumb and three for the fingers.

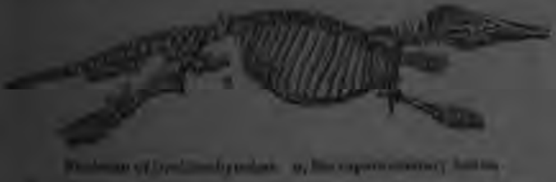
Posterior Extremities.—The pelvis and posterior limbs of the Monotremes are framed more according to the marsupial type; and the animal presents the supernumerary bones which are articulated to the pubis and embedded in the muscles of the abdomen, and are characteristic of that group. Their locality is the same and they are as well developed as in the opossum [MARSUPIALIA, vol. xiv., p. 458]: they are remarkable for the width of their base, which occupies nearly the whole of the anterior border of the pubis. But besides these marsupial bones there are in the external part of the pubis of the *Ornithorhynchus* two external pointed apophyses, one directed outwards, the other forwards. The *ossa ilii* are short, prismatic, and a little enlarged on their anterior border, the pointed tuberosities of the *ossa ischii* are directed backwards, and the *ischium* itself is not soldered to the sacrum as in the other *Edentata*; the three bones join as usual at the cotyloid fossa, but it is to be remarked that the *pubis* and *ischion* equally concur to form the *symphysis*, so that this part of the pelvis is very large and divided crucially by their suture. The oval holes are moderate and very nearly round. The cotyloid fossa is not notched on the side of the oval hole, but in the *Echidna* its bottom is not ossified, and a great aperture is left in that part of the skeleton. In the *Echidna* the *os sacrum* consists of three vertebræ; in the *Ornithorhynchus* it is composed of two only. The *femur* of the latter has no projecting crest, as in *Echidna*; in both animals it is short, wide, and very much flattened. The crests of the *tibia* are not strongly marked: that of the *Ornithorhynchus* is arched or bent, and the animal ordinarily turns its leg like the seals (*Phocæ*) and lizards, so that the nails are directed backwards, the *tibia* and the great toe being towards the outside, the *fibula* and the little finger towards the inside. The *fibula* is nearly straight, very distinct, and tolerably strong, and has on the outside of its upper extremity a large compressed apophysis which is elevated considerably above the head of the bone, offering an extensive surface for the insertion of the muscles. Here may be traced some analogy to the *Cheiroped Marsupials*, which also have the *fibula* very wide above and furnished with a supernumerary bone, which is elevated above the head of the *fibula*. In the *tarsus* the analogy is more to the mammals than the reptiles. In the *Echidna* there is an *astragalus*, an *os calcis*, a *scaphoid* bone, a *cuboid bone*, three *cuneiform* and two supernumerary bones; in the *Ornithorhynchus* there is one more, the *cuboid bone* being separated into two. The *os calcis* of the latter presents a short and blunt tuberosity, and its form is nearly square. The number of the bones of the five toes is the same as in the mammals, and the claws are more curved than those of the fore feet.

Bones of the Trunk.—Though the anterior part of the sternum and shoulder in the *Monotremes* bear a resemblance as those of the Lizards; the rest of that portion of the skeleton exhibits one common analogous to that of quadrupeds. The composition of the sternum is effected by successive pieces, and not by a cartilaginous dilatation as in the Saurians, or a disk composed originally of five pieces as in Birds. There are four of these pieces without reckoning either the Y-shaped bone or the xiphoid cartilage, which in the Ornithorhynchus is ossified and forms a fifth, making six in all. The piece which immediately follows the Y-shaped bone is larger than the others, and in the *Ornithorhynchus* exhibits traces of longitudinal division. The sternal portion of the ribs is ossified, as well as the other, as in Birds, and is joined to the sternum by a cartilaginous portion, but there is no recurrent apophysis to the dorsal ribs as in Birds. The sternal portion of the fifth and sixth ribs is very much dilated in the *Echidna*, and it is also very much dilated but not ossified in the five or six first false ribs; these dilatations extend as far as the eighth in the *Ornithorhynchus*, and become imbricated or laid over each other like tiles. In both genera the three last false ribs have only very small inferior portions. In *Echidna* there are six true and nine false ribs on each side; in *Ornithorhynchus* there are two more false ribs, but only two lumbar vertebræ, whilst *Echidna* has three. Both genera have seven cervical vertebræ, like the rest of the Mammals. In *Echidna* they are flat below, but have a sort of median crest in that direction in *Ornithorhynchus*, and in the latter, even in the adult state, may be still discerned the sutures which unite the transverse apophyses to the body of the vertebræ; here again is an analogy to the Reptiles. The four last dorsal vertebræ in the latter genus have also small inferior crests, which are wanting in *Echidna*; and in the caudal vertebræ a still greater difference exists; *Echidna* has only twelve, rapidly diminishing [illegible], whilst *Ornithorhynchus* has twenty at least, with large and dilated transverse apophyses, forming a depressed tail, which reminds the observer of that of the beaver. The spinous processes throughout have but little elevation, especially in *Ornithorhynchus*. The vertebræ, with the exception of those of the neck, do not retain the sutures which join their parts longer than those of other Mammals.

---

* This figure and the skeleton are taken from a specimen in the museum of the Royal College of Surgeons, by permission of the Museum Committee.

Bone of the Tongue.—It might have been expected that some traces of reptile organization would be found in the os hyoides, but that bone is constructed after the mammiferous type; it is indeed connected in a singular manner with the thyroid cartilage, which is itself singularly divided into four lobes. (*Ossemens Fossiles*, &c.)



Skeleton of Ornithorhynchus. a, the supernumerary bones.

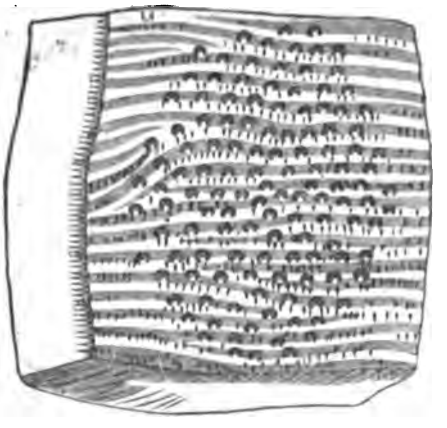
Digestive System.—In the museum of the Royal College of Surgeons in London (*Physiological Series*, No. 323, B) will be found the lower mandible and jaw, with the tongue, larynx, &c. of an *Ornithorhynchus*. On each side, between the coronoid process and the plicated membrane of the jaw, is a horny substance in the form of a molar tooth; that on the right side has been removed to show the vascular substance on which it is based, the elevations of which correspond with the surface of the tooth. Anterior to these are two other and more elongated horny ridges, which may be also considered as teeth. (*Cat.*, vol. 1.) The teeth in the upper jaw are of the same horny substance; the appearance and situation of both will be seen by a reference to the cuts at page 27. In the same museum and series, No. 533, A, is the stomach, in which the cardiac and pyloric orifices are closely approximated, as in the stomachs of birds. The greater part of the cavity extends beyond these orifices, and increases as it descends into the abdomen. The parietes are thin; the two layers of muscular fibres run in opposite directions, and are thickest along the curvature of the pylorus. No. 744, A, exhibits the cloaca. In this preparation the rectum is laid open posteriorly, to show its termination at the fundus of the outer or common cavity, just behind the orifice of the genito-urinary cavity; and two patches of glands are to be seen, one on either side of the anal orifice. The genito-urinary canal is laid open anteriorly, showing the orifice of the urinary bladder at its fundus, and those of the ureters and oviducts at its sides. White bristles are placed in the former, black ones in the latter, which are nearer the urinary bladder than the orifices of the ureters are. No. 541, C, exhibits the pyloric end of the stomach of *Echidna*. (*Cat.*, vol. 1.)

Generative System.—We must now direct the attention of our readers to the mammary glands, as connected with this part of the organization of the *Ornithorhynchus*.

In five apparently adult and full-grown *Ornithorhynchi* examined by Professor Owen, these glands presented as many different degrees of development. In one of the specimens they were even larger than in that dissected by Meckel, measuring in length respectively 5½ inches, in breadth 2, and in thickness half a line. In another specimen they did not exceed 1½ inch in length, and were only five lines in breadth and half a line in thickness. The other individuals exhibited mammary glands of sizes intermediate between these two. The number of lobes composing each gland amounted from 140 to 200; they were elongated, subcylindrical, disposed in an oblong flattened mass, and converged to a small oval areola situated in the abdominal integument, between three and four inches anterior to the cloaca, and about an inch from the mesial line. The lobes in the smaller glands preserved the same breadth to near the points of insertion, but in the larger ones they were broadest at the free extremity, measuring three or four lines across, and becoming narrower in about one-third from the point of insertion, where they ended in slender ducts. The lobes were almost all situated to the outer side of the areola, and consequently converged towards the mesial line of the body. The *panniculus carnosus* was interposed between the glands and the integument, closely adhering to the latter, but connected with the glands by loose cellular membrane. This muscle was here nearly a line in thickness; its fibres were longitudinal, and, separating, left an elliptical space for the passage of the ducts of the gland to the areola.

Portion of the Integument from the abdomen of Ornithorhynchus paradoxus with the hairs removed so as to exhibit the mammary areola. (Owen, *Phil. Trans.*)

Professor Owen further observes, that the areola (when the hair which covers it has been removed) can only be distinguished on the external surface of the skin by the larger size of the orifices of the ducts as compared with those for the transmission of the hairs, and, occasionally, by being of a deeper colour than the surrounding integument. The orifices of the ducts thus grouped form an oval spot, which in the specimen with the largest glands measured five lines in length and three in the short diameter. In that with the smallest glands the areola was traced with a lens to nearly the same extent in the long diameter, but it was much narrower. From the minuteness of the orifices of the ducts in the specimens with the small glands, the situation of the areola could hardly be detected without previously dissecting the gland; whilst in those in which the glands are fully developed, the areola is easily discovered on the removal of the hair by a practised eye. In none of the specimens examined by Mr. Owen was the surface on which the ducts terminated at all raised above the level of the surrounding integument; and he conceives that the elevation like a millet-seed in Meckel's specimen was accidental, and not essential to the structure of the part, Mr. Owen having observed similar risings in the integument at different distances from the areola, but not in the areola itself. The orifices moreover appeared of nearly equal sizes, nor any of them being calculated to suggest the idea of its being common to many ducts or lobules, as might be inferred from M. Geoffroy's description.

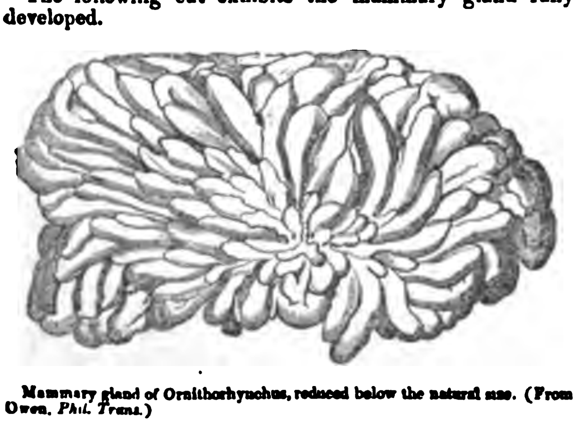


Magnified view of the mammary areola, showing the orifices of the ducts of the glandular lobules. (Owen, *Phil. Trans.*)

Professor Owen states that, on compressing the glands in a specimen in the museum of the Zoological Society of London, where they had arrived at the maximum of development, minute drops of a yellowish oil, which afforded neither perceptible taste nor smell, except what was derived from the preserving liquor, escaped from those orifices. An attempt to insert the smallest absorbent pipe into these orifices failed; but Mr. Owen, having thrust it into the extremity of a lobule, perceived, after a few unsuccessful efforts, the mercury gradually diffusing itself in minute globules through the parenchyma of the lobule; and at the distance of an inch from the place of insertion it had evidently entered a central duct, down which it freely ran to the areola, where it escaped externally from one of the minute orifices just described. This process was repeated on most of the lobes with similar results. Some of the lobules injected by the reflux of the mercury through the anastomosing duct were dried, and various sections examined microscopically by Mr. Owen produced the following results. At the greater end the lobules are minutely cellular; these cells become elongated towards the centre of the lobule, and, as it grows narrower, form minute tubes which tend towards and terminate in a larger central canal or receptacle from which the excretory duct is continued. When uninjected, the entire lobule might, Mr. Owen observes, be readily imagined to be composed of minute tubes; but he adds, that it is difficult to imagine how the lobules can have been considered as hollow cæcums or elongated follicles. On making a section of the corium through the middle of the areola, the ducts were seen by Mr. Owen to converge slightly towards the external surface; but there was no trace of an inverted or concealed nipple, as in the Kangaroo.

The differences in the state of the female organs of generation observed in the Ornithorhynchi, presenting the different conditions of the abdominal glands above described, were such as to indicate that the period of the full activity of those glands was subsequent to that of the uterine functions; whereas, on the hypothesis of their being scent-glands, the relation should have been reversed.

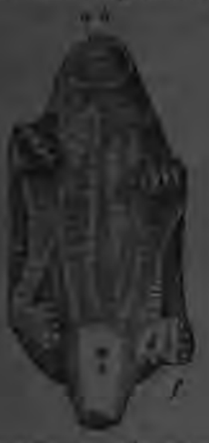
The following cut exhibits the mammary gland fully developed.



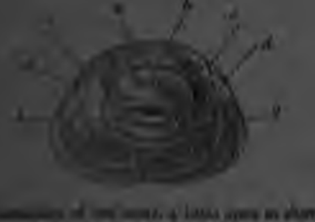
Mammary gland of Ornithorhynchus, reduced below the natural size. (From Owen, *Phil. Trans.*)

The passage of the seminal fluid in the male is by a distinct channel through the penis, though Cuvier denied this. (Dr. Knox and Sir Everard Home.)

The female organs are well displayed in the following preparations preserved in the museum of the Royal College of Surgeons. No. 2734, A (*Physiological Series*) exhibits the female organs and cloaca of an *Ornithorhynchus* in the unexcited state. The left ovarium, an irregular, semi-elliptical, flattened body, has a wrinkled and slightly granulated surface; it is attached to one angle of the wide aperture of the oviduct; the margins of the aperture are extremely thin, and are without fimbriations, as in the *Ovipara*. The wavy convolutions of the oviducts, and the comparatively straight course of the uteri as they pass along the connecting duplicatures of the peritoneum, are seen on both sides. The whole extent of the cloaca is laid open, showing the projecting thickened margins of the uterine orifices, between which is the outlet of the urinary bladder, where a bristle is inserted. Just below the junction of the rectum with the urethro-sexual canal are the orifices of the anal follicles, in two lateral groups. No. 2734, B, of the same series, shows the female organs and cloaca in a state ready for impregnation. The left ovarium is crowded with numerous ovisacs in various stages of development; two of which are conspicuously larger than the rest, and project in a greater part of their circumference from the surface of the ovary. One of these ovisacs (Graafian vesicles) has been laid open and the ovulum with the surrounding granular layer and fluid removed; the other remains entire. The peritoneal capsule of the ovary is divided and turned back from the ovary. The ovarian ligament and the junction of one of its extremities with that of the oviduct appear at the highest point in the preparation. The dilated commencement of the oviduct, or Fallopian tube, with its wide and simple slit-shaped aperture, are left entire. They are adapted to receive the whole ovarium. The contracted part of the oviduct is laid open, showing the irregularly wrinkled or flocculent character of its lining membrane. The right ovarium and ovarian ligament are extended in the preparation transversely below the left. The ovary, which presents itself as a slight granular enlargement of the ligament, contains, nevertheless, many perfect ovisacs and germinal vesicles, which might, possibly, be developed so as to be susceptible of impregnation. The right oviduct, which is much shorter than the left, presents a similar structure. Both uteri are laid open, and are equally developed: they are lined by a thick membrane disposed in very minute oblique wrinkles, and its different colour, due to its greater vascularity as compared with that of the oviduct, is still perceptible. The muscular tunic becomes stronger at the cervix, and continues to increase in thickness to the os uteri, which projects, like the os tincæ in ordinary Mammalia, and also, like the oviduct in the turtle (*Chelonia Mydas*), into the commencement of the urethro-sexual canal, and is traversed, in the virgin state, by a transverse band or hymen. Above and between the ora tincæ appears the orifice of the urinary bladder; and below them are the outlets of the ureters, in which bristles are inserted. This arrangement of those orifices corresponds exactly with that in *Chelonia*. The lining membrane of the urethro-sexual canal is disposed in irregular longitudinal rugæ, which slightly converge to the place of its junction with the rectum, which is seen at the back of the preparation. The common external passage of the cloaca is laid open, and the clitoris and its elongated preputium turned to one side: the bilobed clitoris is exposed at the back part of the preparation, and a bristle is passed through the preputial orifice, which is situated just within the anterior verge of the common external outlet of the cloaca. (*Cat.*, vol. iv.) This preparation is figured by Professor Owen, in *Phil. Trans.* (1832), pl. xvii., to which memoir we refer the student for further particulars. The season of copulation is at the latter end of September or the beginning of the month of October. The precise period of gestation and the condition of the excluded product, strictly speaking, still remain to be determined; but in the first week in December, Mr. G. Bennett found in a nest of an *Ornithorhynchus* three small naked embryos, not quite two inches in length, and which he therefore supposed, with apparently good ground, to have been recently born. The young *Ornithorhynchi* were not preserved, for want of the necessary means of preservation. But Dr. Hume Weatherhead presented to the Zoological Society of London two young specimens a little further advanced than those found by Mr. Bennett. They were of different sizes. The smallest rather exceeded two inches in length, measured from the end of the bill to the end of the tail in a straight line. The largest was double that size, and was one of the two young *Ornithorhynchi* taken with the mother from a nest on the banks of the Fish River by Lieut. the Honourable Lauderdale Maule, and kept alive for about a fortnight by that gentleman. These specimens were placed in the hands of Professor Owen for examination, and form the subject of his paper in the first volume of the *Transactions of the Zoological Society*. Our limits will not permit us to follow the Professor throughout this interesting memoir, to which we refer our readers; but there are some points which must be noticed. The stomach of the larger specimen was found full of coagulated milk. On carefully inspecting the whole contents with a lens, no portions of worms or insects could be detected; which, Mr. Owen observes, solves the doubt entertained by Lieut. Maule as to whether the mother nourished the young one with the food which was given to her for her own support, or with the secretion afterwards discovered to escape from the mammary pores; for the mother having been killed by accident on the fourteenth day after her captivity, it was observed, on skinning her while yet warm, that milk oozed through the fur on the stomach. A portion of the coagulated milk from the stomach of the young one was diluted with water and examined by Professor Owen under a high magnifying power, in comparison with a portion of cow's milk coagulated by spirit and similarly diluted. The ultimate globules of the *Ornithorhynchus's* milk were distinctly perceptible, detaching themselves from the small coherent masses to form new groups; the corresponding globules of the cow's milk were of larger size. With the milk globules of the *Ornithorhynchus* minute transparent globules of oil were intermixed. So far the experiment may be considered to have been decisive; but, to prevent the possibility of doubt, Professor Owen took a little mucus, and added a drop of water to it, when it instantly became opaque; and its minutest divisions under the microscope were into transparent angular flakes, entirely different from the regularly formed granules of the milk of the *Ornithorhynchus*.

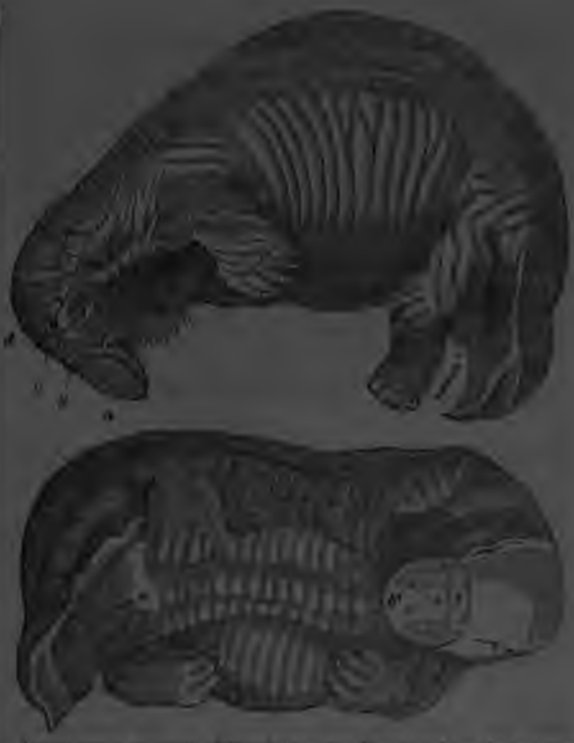


Under surface of young *Ornithorhynchus* (natural size): a, nostrils; b, prominence on the upper mandible; [illegible] f, the [illegible] and rudimentary spur of the hind foot.



[illegible] of the mouth a little open to show the tongue; a, nostrils; b, prominence of the upper mandible; c, the eyes; d, the [illegible]; g, the [illegible]; h, the tongue.

[illegible]



Larger young specimen of *Ornithorhynchus* (two views): a, the nostrils; b, the prominence on the upper mandible; c, the eyes; [illegible] [Owen, Zool. Trans.]

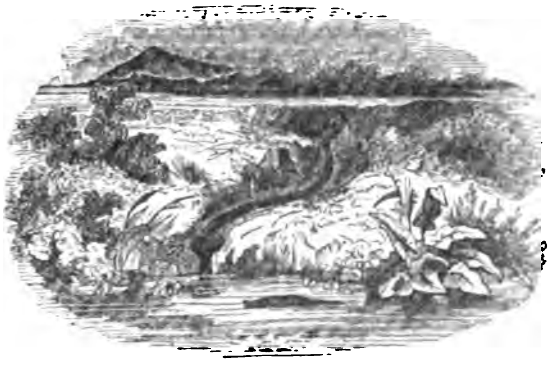
The circumstances particularly worthy of attention in these young animals are, the total absence of hair, the soft and flexible condition of the mandibles, and the shortness of these parts in proportion to their breadth as compared with the adult, as Mr. Owen pointed out. The tongue, which in the adult is lodged far back in the mouth, advances in the young animal close to the end of the lower mandible, and its breadth is only one line less in an individual four inches in length than it is in fully grown animals; a disproportionate development which is plainly indicative, as Mr. Owen remarks, of the importance of the organ to the young *Ornithorhynchus*, both in receiving and swallowing its food.

On the middle line of the upper mandible, and a little anterior to the nostrils, there is a minute fleshy eminence, *b*, lodged in a slight depression. In the smaller specimen this is surrounded by a discontinuous margin of the epidermis; with which substance therefore, probably from its having been shed, of a thickened or horny consistence, the caruncle had been covered. There is no trace of this structure in the upper mandible of the adult, and Professor Owen regards it as analogous to the fœtal peculiarity of the horny knob on the upper mandible of the *bird*. He does not however conceive that this remarkable example of the affinity of *Ornithorhynchus* to the feathered class is indicative of its having been applied, under the same circumstances, to overcome a resistance of precisely the same character as that for which it is designed in the young bird, since all the known history of the ovum of *Ornithorhynchus* points strongly to its ovoviviparous development. Lieutenant Maule's communication not only showed that the fluid secreted by the abdominal glands is milk, but also that the ova of *Ornithorhynchus* attain the size of a large musket-ball, and, like the eggs of the ovoviviparous reptiles, have a soft outer covering. The supposed portions of egg-shell found by Lieutenant Maule in the nest were probably portions of excrement, coated, as in birds, with the salts of the urine, that secretion and the fæces being expelled by the same orifice. The situation of the eyes, *c*, is indicated in the young by the convergence of a few wrinkles to one point;

but the integument is continuous, and completely shrouds the eyeball. Upon this Professor Owen remarks that the absence of vision in the young animal affords strong evidence of its being confined to the nest, there to receive its nourishment from the dam; and this is, he observes, corroborated by the cartilaginous condition of the bones of the extremities, and by the general form of the body: the head and tail are closely approximated on the ventral aspect, requiring force to pull the body into a straight line; and he adds that the relative quantity of integument on the back and belly shows that the position necessary for progressive motion is unnatural at this stage of growth.

Nervous System and Senses.—The senses of hearing and seeing appear to be sufficiently acute in the adult *Ornithorhynchi.* Smell and taste must also exist in considerable perfection. (Ante, p. 30.) The extremities of the mandibles are probably endowed with an acute sense of touch.

Food, Habits, &c.—Lieut. Maule fed the female which he kept in captivity on worms and bread and milk. Mr. G. Bennett, in his paper 'On the History and Habits of the *Ornithorhynchus paradoxus*' (*Zool. Trans.*, vol. i.), gives the following account of one when feeding, which he had secured by a cord fastened to the hind-leg:—'It was exceedingly lively, swam in the centre of the stream, and appeared in excellent health and spirits. The water at one part of the river being very clear, I saw its motions distinctly under the water. On diving, it sank speedily to the bottom, swam there for a short distance, and then rose again to the surface; it ranged the banks, guiding itself in its progress according to the impressions received by the mandibles, which appeared to me to be used by it as very delicate organs of touch. It seemed to feed well; for whenever it inserted its beak into the mud, it evidently procured some food from thence, as, on raising the head, after withdrawing the beak, the mandibles were seen in lateral motion, as is usual when the animal masticates. Although several insects were basking and fluttering about the surface of the water, close to it, no attempt was made to capture them, either from its not seeing them, or from its preferring the food which the mud afforded. The motions of the mandibles in this animal, when seeking its food in the mud and water, are the same as those of a *duck* when feeding in similar situations. After feeding, it would lie sometimes on the grassy bank, and at others partly in and partly out of the water, combing and cleaning its coat as usual with the claws of the hind feet. After permitting it to swim, feed, and clean itself for an hour, it was replaced, although with great reluctance on its own part, in its box: it did not however, as before, betake itself to repose, but commenced and continued a scratching on the sides of the box.' The same author states that these animals feed on the minute *Testacea* which may be found about the water-plants and in rivers. On examining the cheek-pouches or the stomachs of these animals, he always observed the food to consist of river insects, very small shell-fish, &c., which were constantly found comminuted and mingled with mud or gravel, probably to aid digestion. River weeds have also been found in their pouches, and the natives say they feed on them also. In the museum of the Royal College of Surgeons are preserved the débris of insects belonging to a genus of the *Naucerideæ*, which were found in the cheek-pouches of an Ornithorhynchus. (*Physiological Series*, No. 541, B.) We owe to Mr. G. Bennett, who has contributed so much to our knowledge of the natural history of this and other scarce animals, a description of the burrows of these extraordinary creatures. They were traced up a bank of a river, where, amongst some long grass, the entrance of a burrow was discovered, and the internal construction of it was laid open by digging. The entrance was large, particularly when compared with the width of the passage continued from it, measuring one foot three inches in depth, and one foot one inch in breadth. As it receded from the entrance, the burrow became narrower, being about the usual breadth of the animal when uncontracted. 'After having traced it,' continues Mr. Bennett, 'for the distance of ten feet four inches, and having just delved down upon it so as to perceive it still continuing its course up the bank, the beak and head of a *Water Mole* were seen protruding for an instant from the upper part, as if it had been disturbed from its repose, and had come down to see what we were about with its habitation. It only remained for an instant; for, as soon as it beheld us, * * it immediately turned up to take refuge in that part of the burrow which yet remained unexplored. In turning round however it was seized by the hind leg and dragged out. The animal appeared very much alarmed when it was hauled out of its subterraneous dwelling: it discharged its urine (which had rather a strong odour) and its fæces, when first caught, which I attributed to fear, for this is not usual with other living specimens that I have since seen. It uttered no sound, nor did it attempt to bite; and proved to be a full-grown female. When I held the unfortunate *Platypus* in my hands, its bright little eyes glistened, and the orifices of the ears were expanded and contracted alternately, as if eager to catch the slightest sound, while its heart palpitated violently with fear and anxiety. * * This animal uttered, when disturbed from its sleep, a noise something like the growl of a puppy, but perhaps in a softer and more harmonious key. Although quiet for the greatest part of the day, it made efforts to escape, and uttered a growling noise during the night.' But we must return to the burrow, the distance of the entrance of which from the water's edge was five feet. It ran up the bank in a serpentine course, approaching nearer to the surface of the earth towards its termination, at which part the nest, composed of dried grass, and weeds strewed over the floor, is situated; but none had been as yet made in this burrow. The termination, of the form shown in the cut, measured one foot in length by six inches in breadth. Mr. Bennett found the whole extent of the burrow, from the entrance to the termination, to be twenty feet by actual measurement. He observes that the burrows are situated above the usual river height, but do not appear to be above the extensive floods of the river, which frequently take place during the winter season.



Burrow of Ornithorhynchus. (Reduced from Bennett, *Zool. Trans.*)

The reader will find information of much interest in Mr. Bennett's paper, particularly with regard to the habits of two full-furred young ones, a male and a female, which he kept for some time. They were taken from the nest, which consisted of river-weeds, the epidermis of reeds and small dry fibrous roots strewed over the floor of the cavity, which was large enough to contain the mother and her young: these are from two to four in number, but most usually two.

Description.—Authors generally describe two species, viz. *Ornithorhynchus rufus*, and *Ornithorhynchus fuscus*; but the probability is that they are but varieties of one species, if indeed the difference may not be merely that of age or sex. The males are rather larger than the females, and Mr. Bennett considers the average length to be from 1 foot 6 inches to 1 foot 8 inches. A male shot in the Yas river measured, from the extremity of the mandible to the extremity of the tail, 1 foot 7¾ inches, and a female shot in the same river was 1 foot 7 inches, measured in the same way. The following is an abridgment of his description. *Body* depressed, partaking in some degree of the characters of the Otter, the Mole, and the Beaver, covered by a fine long thick hair, beneath which is a finer, short, very soft fur, like the two kinds of hair found in the Seal and Otter. Colour above, light black, varying in shades according as it is seen in a stronger or weaker light; beneath, where the fur and hairs are finer, ferruginous, varying in intensity according to age. *Tail* flat, broad, and inclining on each side abruptly off at the termination, beyond which the long hairs project; on its upper surface the hair longer and coarser than elsewhere. In young specimens its under surface, as well as the hind and fore legs near the feet, covered by fine silvery white hair. Below the inner angle of the eye (which is small, but brilliant and of a light brown colour) a small spot of light or pale yellow colour. External orifice of the ear situated near the upper part of the external angle of the eye. This orifice is seen with difficulty in dead specimens. *Head* rather flat; *mouth* furnished with two projecting flat lips or mandibles, resembling the bill of a *Shoveler Duck* [Duck, vol. ix., p. 179], the lower of which is shorter and narrower than the upper, and has its internal edges channelled with numerous *striæ*, resembling in some degree those seen in the bill of a *Duck*. The central portion of the mandibles is a bony continuation from the skull, and anteriorly and laterally a cartilaginous substance, partially moveable, extends from the bony portion to the distance of 3/8ths of an inch. Colour of upper mandible above, when seen in an animal recently taken out of the water, dull dirty greyish black, covered with innumerable minute dots, while the cartilaginous expansion around the mandible is smooth and soft. Under part of upper mandible pale pink or flesh colour, as well as the internal or upper surface of the lower mandible, the under surface of which last is sometimes white, sometimes mottled; the former mostly in young specimens; the latter usually in adults. At the base of both lower and upper mandibles a transverse loose fold or flap of integument, similar in colour to the skin covering the mandibles. This is continued in the upper mandible very nearly to the eyes.* *Feet* five-toed and webbed. In the fore-feet the web extends a short distance beyond the claws, is loose, and falls back when the animal burrows; claws strong, blunt, the two lateral shorter than the three middle ones. Hind-feet short, narrow, turned backwards, and, when the animal is at rest, somewhat resembling a fin; their action is backwards and outwards; first toe very short, and the nails of all curved backwards, and longer and sharper than those of the fore-feet; the web does not extend beyond the roots of the claws. The spur of the male (the female is destitute of this organ) is moveable, turned backwards and inwards, and situated some distance above the claws, and rather towards the internal part of the leg.

We cannot quit this part of the subject without calling the reader's attention to the beautiful organization of the *fore-foot of the Ornithorhynchus*. In the museum of the College of Surgeons (*Physiological Series*, No. 251, A.) one of these fore-feet is preserved, and the natatorial membrane will be seen continued for some distance beyond the termination of the toes, and gathered into folds at each toe. These folds are concave towards the palm, and are supported behind by the strong elongated claws, presenting a broad surface admirably adapted for striking the water with effect.

The spur of the male has been pretty generally considered as a weapon of offence and a very venomous one; but Mr. G. Bennett's experiments go far to prove that this idea is unfounded. He thus relates his experience in the case of a wounded male just taken out of the water: 'Having heard so much related about the injurious effects resulting from a puncture by the spur, I determined to avail myself of the opportunity to ascertain the correctness of the assertion. The wounded state of the animal presented no objection to the experiment, as in one published account, in which the poison is reported to have produced such terrible effects, the animal was also mortally wounded. As soon therefore as it became lively, I put its "poisonous spurs" to the test. I commenced by placing my hands in such a manner, when seizing the animal, as to enable it, from the direction of the spurs, to use them with effect: the result was that the animal made constant efforts to escape, and in these efforts scratched my hands a little with the hind-claws, and even, in consequence of the position in which I held it, with the spurs also. But although seized so roughly, it neither darted the spur into my hand, nor did it even make an attempt so to do. As however it had been stated that the creature throws itself on the back when it uses this weapon (a circumstance not very probable to those who have any knowledge of the animal), I tried it also in that position; but though it struggled to regain its former posture, no use was made of the hind claws. I tried several other methods of effecting the object I had in view, but as all proved futile, I am convinced that some other use must be found for the spur than as an offensive weapon. I have had several subsequent opportunities of repeating the experiments with animals not in a wounded state, and the results have been the same.'

Place in the System.—Dr. Shaw referred *Ornithorhynchus* to the *Bruta* of Linnæus, and Professor Blumenbach, less correctly, to the *Palmata* in his system, placing it between the *Otter* and the *Walrus*. Lamarck, Van der Hoeven, and Professor Geoffroy St. Hilaire characterized the *Monotremata* as a class intermediate between quadrupeds and birds. The base of the last-mentioned arrangement was the presumed want of mammary glands. Cuvier, as we have seen, more philosophically, admitted the forms into his 'Règne Animal' as a tribe or family of his order *Edentata*. M. de Blainville considered the *Monotremata* as most closely approximated to the *Marsupialia*. Meckel arranged them among the *Mammalia*, next to the *Edentata*. Mr. Gray, in his 'Outline,' placed *Echidna* and *Ornithorhynchus* in the 5th subfamily (Ornithorynchina*) of his 4th family (*Tatusiadæ*), This fifth subfamily being immediately preceded by the *Myrmecophagina*. J. B. Fischer, in his 'Synopsis,' arranges the two forms at the end of the *Bruta*, which are immediately succeeded in his work by the *Belluæ*. M. Lesson makes the *Monotremata* the second and last tribe of the order *Edentata*; and the same situation is assigned to them by Mr. Swainson. Mr. Owen arranges them in the *Ovoviviparous Subclass* of Mammals, and, in the course of his valuable papers, exhibits their affinities to birds, reptiles, the Marsupial animals, and the ordinary mammiferous type.

The following cuts are taken from Mr. G. Bennett's paper in the 'Transactions of the Zoological Society.'

Ornithorynchus feeding.

Ornithorynchus sleeping.

---

* Mr. Bennett thinks that this may afford some protection to the eyes when the animal is engaged in burrowing or seeking its food. Mr. Everard Home considers that the latter are apparently destined to prevent the bill from being pushed into the mud and sand, beyond those parts.

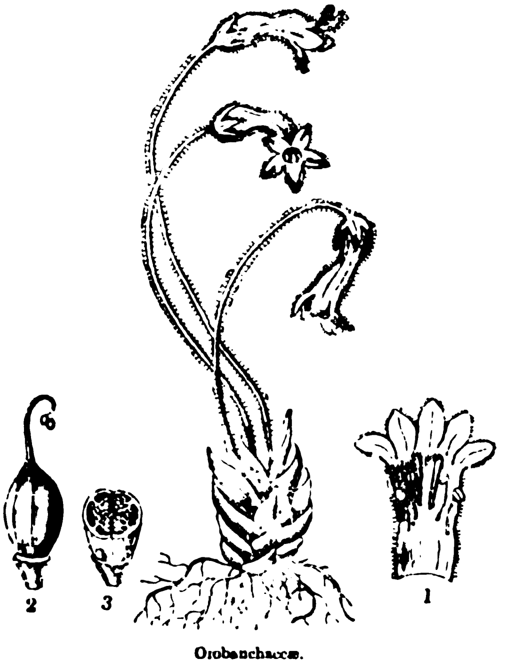
* Ornithorhynchina.

Ornithorhynchus combing itself with the claws of the hind-foot.

We cannot close this article without adverting to the subject of it as a satisfactory instance of the rapidity and accuracy of the progress of modern investigation. When this extraordinary animal was first brought over, we find Dr. Shaw, in 1799, noticing the scepticism with which it was received, not only as pardonable but laudable; almost doubting the testimony of his own eyes with respect to the structure of the animal's beak, yet confessing that he can perceive no appearance of any deceptive preparation; adding that the edges of the *rictus*, the insertion, &c., when tried by the test of maceration in water, so as to render every part completely moveable, seem perfectly natural; and concluding by a statement that the most accurate examination of expert anatomists could not discover any deception in that particular. The form is now as familiar to us as most of our European animals, and with regard to its organization and natural history, it is perhaps better known than many.

ORNUS. [MANNA.]

OROBANCHA'CEÆ are a natural order of Monopetalous exogenous plants, growing parasitically upon the roots of other species, and, as is very usual in such cases, producing no true leaves, but furnished with brown or reddish scales in their place. They have a didynamous structure, irregular flowers, and a superior ovary with four or more parietal placentæ, which spring up from the surface of the carpels in parallel lines covered with microscopical seeds containing a minute embryo lying in abundant albumen. On account of their didynamous monopetalous flowers, they are usually stationed by systematical writers in the vicinity of Scrophulariaceæ, but in many respects they correspond better with the typical form of Gentianaceæ. In this country the order is represented by the genus Orobanche itself, the various species of which, called Broomrapes, are found in fields, upon the roots of broom, furze, hemp, clover, bedstraw, &c. *O. rubra*, the handsomest of them, has hitherto been discovered only upon basalt and trap rocks in the Hebrides and adjacent shores, and near Belfast. The quality of these plants seems to be generally astringent, but they have been little investigated.



Orobanchaceæ.

plant of Anoplanthus uniflorus. 1, a corolla slit open: 2, the ovary with yle and stigma; 3, the same, cut across to show the placentation.

ORO'DES. [CRASSUS.]

ORONTES. [SYRIA.]

OROONOKO. [ORINOCO.]

ORO'SIUS, PAULUS, a presbyter of the Spanish church, was born in the latter part of the fourth century, probably at Tarracona. About A.D. 414 he proceeded to Africa, for the purpose, as it seems, of consulting St. Augustin on several controverted points of belief, which were then discussed by the sects of the Priscillianists and the Origenists, especially concerning the nature and origin of the soul. ('Consultatio sive Commonitorium Orosii ad Augustinum de errore Priscillianistarum et Origenistarum,' together with Augustin's answer, 'Ad Orosium contra Priscillianistas et Origenistas,' both in the collection of the works of St. Augustin.) From Africa, Orosius proceeded to Palestine with a recommendation from Augustin to Jerome, who was then living at Bethlehem. While in Palestine, Orosius wrote a treatise against Pelagius, who was at that time spreading his opinions concerning original sin and grace, 'Liber apologeticus contra Pelagium de Arbitrii Libertate,' which is annexed to the 'History' of Orosius. From Palestine, Orosius returned to Hippo Regius, to his friend Augustin, and from thence to Spain. He now began to write his 'History of the World,' a work which he seems to have undertaken at the suggestion of Augustin, to whom it is dedicated. The history ends with the year A.D. 416, about which time it appears to have been completed.

The calamities which had befallen the Roman empire, and above all the capture and pillage of Rome by Alaric, A.D. 410, afforded to the heathens and to Symmachus, among the rest, a pretence for accusing the Christian religion of being the cause of all those disasters, and of saying that since the abandonment of the old religion of the state, victory had utterly forsaken the Roman arms. It was for the purpose of replying to these accusations that Orosius wrote his history, which may be considered in part as an apology for Christianity against the Pagans, as the title, which has been found in several MSS., expresses,—'Adversus Paganos Historiarum libri vii.' In some MSS. the title is, 'De totius Mundi Calamitatibus;' in others, 'De Cladibus et Miseriis Antiquorum,' &c. The work consists of seven books, divided into chapters. It begins with a geographical description of the world, then treats of the origin of the human race according to the Book of Genesis, and afterwards relates the various accounts of the mythologists and poets concerning the heroic ages. Then follows the history of the early monarchies, the Assyrian, Babylonian, and Persian, the conquests of Alexander, and the wars of his successors, as well as the early history of Rome, the contents being chiefly taken from Trogus Pompeius and Justinus. The fourth book contains the history of Rome from the wars of Pyrrhus to the fall of Carthage. The fifth book comprises the period from the taking of Corinth to the war of Spartacus. Orosius quotes his authorities, several of which are from works which are now lost. The narrative in the sixth book begins with the war of Sulla against Mithridates, and ends with the birth of our Saviour. The seventh book contains the history of the empire till A.D. 416, including a narrative of the taking and sacking of Rome by Alaric, which was the great event of the age.

Orosius intermixes with his narrative moral reflections, and sometimes whole chapters of advice and consolation, addressed to his Christian brethren, and intended to confirm their faith amidst the calamities of the times, which, however heavy, were not, as he asserts, unprecedented. The Romans, he says, in their conquests had inflicted equal if not greater wrongs on other countries. His tone is that of a Christian moralist impressed with the notions of justice, re attention and humanity, in which most of the heathen historians show themselves deficient. He deprecates ambition, conquest, and glory gained at the expense of human blood and human happiness. As an historian, Orosius shows considerable critical judgment in general, though in particular passages he appears credulous, as in chap. x. of the first book, where he relates from report that the marks of the chariot wheels of Pharaoh's host are still visible at the bottom of the Red Sea. As an instance of the incidental value of the passages taken by Orosius from older writers, see Savigny, *Das Recht des Besitzes*, p. 176.

King Alfred made a free translation of the History of Orosius into the Anglo-Saxon language, which has been published by Daines Barrington, with an English version of it, 8vo., London, 1773.

One of the best editions of Orosius is that of Leyden, 4to., 1738, with Havercamp's notes.

ORPHEUS (Ὀρφεύς), a poet, musician, and philosopher, whose name is very prominent in the early legends of Greece. The traditions respecting him are remarkably obscure. According to Cicero (*De Nat. Deor.*, i. 38), Aristotle believed that no such person as Orpheus the poet had ever existed; but perhaps he only meant that the poems ascribed to Orpheus were spurious: he is mentioned as a real person by several of the early Greek writers—the lyric poets Ibycus and Pindar, the historians Hellanicus and Pherecydes, and the Athenian tragedians; he is not mentioned by Homer or Hesiod. Some antient writers reckon several persons of this name, and Herodotus speaks of two. In later times, a number of marvellous stories were connected with his name. The following is an outline of the legendary history of Orpheus. His native country was Thrace. It is a remarkable fact that most of the legends respecting Greek civilization are connected with the Thracians, who, in later times, spoke a language unintelligible to the Greeks, and were looked upon by them as barbarians. Müller explains this by pointing out that the Thracians of these legends were not the same people as those of the historical period, but a Greek race, who lived in the district called Pieria, to the east of the Olympus range, to the north of Thessaly, and to the south of Emathia or Macedonia. ('History of the Literature of Greece,' in *Library of Useful Knowledge*, p. 26.) The time in which he lived is placed by all writers not long before the Trojan war, and by most at the period of the Argonautic expedition, about twelve or thirteen centuries before Christ. He was the son of Apollo and the muse Calliope, or, according to other accounts, of Oeager and a muse. The poets represent him as a king of Thrace, but the historians are generally silent about his station. According to Clemens of Alexandria, he was the disciple of Musæus, but the more common accounts make him his teacher. He was one of the Argonauts, to whom he rendered the greatest services by his skill in music; the enchanting tones of his lyre made the Argo move into the water, delivered the heroes from many difficulties and dangers while on their voyage, and mainly contributed to their success in obtaining the golden fleece. (Orphei *Argonautica*.) After the voyage, he returned to the cavern in Thrace in which he commonly dwelt. He is said by some authors to have made a voyage to Egypt before the Argonautic expedition.

Orpheus had for his wife a nymph, named Eurydice, who died from the bite of a serpent as she was flying from Aristæus. Orpheus followed her to the world beneath, and by the power of his lyre induced Pluto and Proserpine to restore his wife, but upon the condition that he should not look back at her till he had past the boundaries of Pluto's realm. He broke the condition, and she vanished from his sight.

His death is differently related. The most common account is that he was torn in pieces by the Thracian women at a Bacchic festival, in revenge for the contempt which he had shown towards them through his sorrow for the loss of Eurydice. (Apoll., i. 3; Virg., *Georg.*, iv. 454.) His limbs were scattered over the plain, but his head was thrown upon the river Hebrus, which bore it down into the sea as far as Lesbos, where it was buried. The Muses gathered up the pieces of his body, and buried them at Libethra, where the nightingale was said to sing over his grave more sweetly than in any other part of Greece. His lyre was placed by Jupiter among the stars.

The poets and scholiasts have attributed to Orpheus many great improvements in the condition of the human race. Nearly all the antient writers state that he introduced into Greece the knowledge of religion and the worship of the gods. The foundation of mysteries is ascribed to him. (*Aristoph.*, *Ranæ*, v. 1030; Eurip., *Rhesus*, v. 943; Plato, *Protag.*, p. 316.) Herod. (ii. 81) speaks of Orphic and Bacchic mysteries. These mysteries seem to have been different from those of Eleusis. [ORPHICA.] Some writers say that the Orphic mysteries were introduced from Egypt into Greece; others think that they sprung up in Thrace, and that they preceded the worship of Dionysus, which was of foreign origin, and that the destruction of Orpheus by the Bacchanals represents the victory of the new over the old religion. The foundation of social institutions and the commencement of civilization is ascribed to Orpheus. (Horat., *De Art. Poet.*, v. 391.) Aristophanes says that he taught men to abstain from murder (*Ranæ*, v. 1030). He is said to have been the author of many fables. A passage in an epigram, to which however no authority can be attached, ascribes to him the discovery of letters. (Fabric., *Bib. Græc.*, i., p. 173.) The discovery of many things in medicine is ascribed to Orpheus (Plin., xxv. 2); and the recal of Eurydice from the lower world is sometimes explained as referring to his skill in this art. He was said to have been a soothsayer and enchanter. In Lesbos there was a famous oracle of Orpheus. The most remarkable of the legends concerning him are those which relate to his skill in music. The fable that by the tones of his lyre he drew around him wild beasts, trees, and stones, is very old. When, according to a later story, he descended into the infernal regions to recover Eurydice, his music enchanted the world of shadows and suspended the torments of the damned. A share in the invention of the lyre is attributed to him: he received it from Apollo with seven strings, and added to it two more. According to Plutarch, he was the first who accompanied the lyre with singing. The fable that after his death his lyre floated to Lesbos, is a poetical mode of representing the skill of the natives of that island in lyric poetry. He is said to have embodied his religious and philosophical opinions in poems, but the works ascribed to him are without doubt spurious. [ORPHICA.]

ORPHEUS (Ornithology). [MERULIDÆ, vol. xv., p. 122; MOCKING BIRD.]

O'RPHICA, certain works falsely ascribed to Orpheus, which embodied the opinions of a class of persons whom Müller thus describes:—'These were the followers of Orpheus (οἱ Ὀρφικοί); that is to say, associations of persons who, under the guidance of the antient mystical poet Orpheus, dedicated themselves to the worship of Bacchus, in which they hoped to find satisfaction for an ardent longing after the soothing and elevating influences of religion. The Dionysus, to whose worship these Orphic and Bacchic rites (τὰ Ὀρφικὰ καλεόμενα καὶ Βακχικά, Herod., ii. 81) were annexed, was the Chthonian deity Dionysus Zagreus, closely connected with Demeter and Cora, who was the personified expression, not only of the most rapturous pleasure, but also of a deep sorrow for the miseries of human life. The Orphic legends and poems related in great part to this Dionysus, who was combined, as an infernal deity, with Hades (a doctrine given by the philosopher Heraclitus as the opinion of a particular sect); and upon whom the Orphic theologers founded their hopes of the purification and ultimate immortality of the soul. But their mode of celebrating this worship was very different from the popular rites of Bacchus. The Orphic worshippers of Bacchus did not indulge in unrestrained pleasure and frantic enthusiasm, but rather aimed at an ascetic purity of life and manners. The followers of Orpheus, when they had tasted the mystic sacrificial feast of raw flesh torn from the ox of Dionysus (ὠμοφαγία), partook of no other animal food. They wore white linen garments, like the Oriental and Egyptian priests, from whom, as Herodotus remarks, much may have been borrowed in the ritual of the Orphic worship.' ('History of the Literature of Greece,' in the *Library of Useful Knowledge*, p. 231, &c., where the reader will find a full account of the Orphic theology.)

Of the Orphic writers the most celebrated are Onomacritus, who lived under Pisistratus and his sons, and Cercops, a Pythagorean, who lived about B.C. 504. Works ascribed to Orpheus were extant at a very early period. Plato mentions several kinds of Orphic poems; but he intimates that they were not genuine. Aristotle speaks of them as the *so-called* Orphic poems (τὰ καλούμενα). In later times all manner of works on mysteries and religion were ascribed to Orpheus. There are also Orphic poems later than the Christian æra, which are difficult to be distinguished from those of earlier times. In Fabricius's 'Bibliotheca Græca' there is a list of the writings ascribed to Orpheus, of which the following are the principal.

1. Ἱεροὶ λόγοι (*sacred legends*), a complete system of Orphic theology, in twenty-four books; it is ascribed to Cercops and Diognetus, and is probably the production of several authors.

2. Τελεταί (*religious rites*, or *mysteries*), directions for worshipping and appeasing the Gods; probably by Onomacritus.

3. Χρήσμοι (*prophecies*). Similar works were ascribed to Musæus.

4. Βάκχικα, probably stories of Bacchus and his mysteries; ascribed to Arignotes, a pupil or daughter of Pythagoras.

5. Ἡ ἐς Ἀΐδου κατάβασις (*the descent to Hades*), a poem of great antiquity, ascribed, among other authors, to Cercops.

6. *Hymns*, also of high antiquity. In the time of Plato they were recited by rhapsodists at the public games. Onomacritus appears to have been the author of many of them.

7. *Of Stones*, their nature, and their powers against serpents and poisons, and for appeasing the anger of the gods.

8. *Argonautica*, a poem on the voyage of the Argonauts to Colchis; probably by Onomacritus; at least by some one not earlier than Homer.

9. *Fragments*, which have been carefully collected by Gesner out of Platonic and Christian writers. Most of them are of a later date than the Christian æra.

The following are the principal editions of the Orphic poems: 'Orphei Argonautica, Hymni, et de Lapidibus,' Gr., in H. Stephens's 'Poetæ Græci Principes Heroici Carminis,' 1566, fol.; Orphei Argonautica, Hymni, et de Lapidibus, curante A. C. Eschenbachio, cum not. erudit.,' Utrecht, 1689; Ὀρφέως ἅπαντα, 'Orphei Arg., Hym., de Lapid., et Fragmenta, cum notis Stephani et Eschenbachii, ex recens. et cum not. J. M. Gesneri,' Lips., 1764; 'Orphica,' by Schaeffer, Lips., 1818; ditto, by Hermann, Lips., 1805; 'Argonautica,' by Schneider, Jena, 1803.

Tiedemann's *Initia Philos. Græc.*, p. 1-100; Fabric., *Bib. Græc.*, i., p. 140, &c.; Clinton's *Fasti;* Funke's *Real. Schullexicon.*)

ORPIMENT. [ARSENIC.]

ORPINE is a succulent herbaceous plant, the Sedum Telephium of botanists, found abundantly in some parts of England in woods and thickets. It has oval serrated leaves, erect stems, and close carpels of purple flowers; and has some reputation for its astringency: the root and stem, boiled in milk, are a popular remedy for diarrhœa.

ORRERY. There are four planetary machines to which distinct names have been given, corresponding to the phenomena they are intended to exhibit, and which, when combined so as to derive their motions from a common origin, constitute what is now generally understood by an orrery. These machines are the Planetarium, Tellurian, Lunarian, and Satellite machine. The planetarium is a mechanical representation of the orbital motions of the planets about the sun, either in circles or ellipses, and with angular velocities either uniform or variable, according to the quality of the instrument. The tellurian and lunarian, when connected in their improved form, exhibit the motion of the moon about the earth and that of the earth about the sun, and the principal phenomena which accompany the changes in their relative positions, such as the succession of day and night and the variable length of both according to the season of the year, the eclipses of the sun and moon, the variations in the moon's latitude, velocity, and distance from the earth, the progressive motion of her apogee, and the retrogradation of her nodes, &c. The satellite machine is chiefly intended to represent the motions of Jupiter's satellites about their primary, combined with the motions of the latter about the sun. Instead of attempting a particular description of any one of these machines, which could only be rendered intelligible by reference to many diagrams, while the object would be much better attained by a simple inspection of the machine itself, we shall confine ourselves to a brief notice of their history and to the explanation of the general principles upon which the construction of modern planetary machines depends, referring our readers for more ample in- rmation to the article 'Planetary Machines' in Brewster's *clopædia*, contributed by the Rev. W. Pearson, formerly asurer of the Astronomical Society.

The origin of the term 'orrery' is thus given by Mr Desaguliers, in his 'Course of Experimental Philosophy,' 4to., London, 1734, i., p. 431. After stating his belief that Mr. George Graham, about the year 1700, first invented a movement for exhibiting the motion of the earth about the sun at the same time that the moon revolved round the earth, he remarks, 'This machine being in the hands of an instrument-maker to be sent with some of his own instruments to Prince Eugene, he copied it, and made the first for the late Earl of Orrery, and then several others with additions of his own. Sir Richard Steele, who knew nothing of Mr. Graham's machine, in one of his lucubrations, thinking to do justice to the first encourager, as well as to the inventor, of such a curious instrument, called it an *orrery*, and gave Mr. J. Rowley the praise due to Mr. Graham.'

Planetary machines were in use at a very remote period, and appear to have consisted for many centuries of moveable spheres having the earth in their centre: thus we read of the Chinese spheres said to have been made some 2000 years before the Christian æra, and more recently of the spheres of Archimedes and Posidonius, concerning which Cicero, speaking of the Epicurean philosophy, has the following remarkable passage:—

'If the sphere, lately made by our friend Posidonius, which marks the course of the sun and moon and the five wandering stars, were to be transported into Scythia or Britain, who, even in those barbarous countries, would doubt whether reason had presided over its construction? Yet these people (the Epicureans) doubt whether the universe, whence all things arise and are made, is not the effect of chance or of some necessity rather than of reason and a divine mind; and they regard Archimedes as more deserving of praise in imitating the changes of the sphere than nature in producing them.' (*De Nat. Deor.*, lib. ii., cap. 34 and 35.)

The earliest machine which represented the Ptolemaic system may possibly have been that possessed by Chromatus, in the construction of which no less than 200 pounds weight of gold are said to have been used. This system continued to be represented in all planetary machines till about fifteen years after the death of Copernicus, when the last of that kind of any note was erected in the library of the Pantheon at Paris by Oronce Finée.

In the latter part of the seventeenth century Huyghens and Roemer employed themselves in the construction of planetary machines in conformity with the Copernican doctrine. The one invented by Huyghens, who first introduced a systematic method of calculating with precision the necessary wheel-work for these machines, received from its author the name of 'the Automaton.' It derived its motion from a spring regulated by a balance, the pendulum not having been then introduced as a regulating agent, and served for many years as a pattern in the construction of orreries, as did the instrument of Roemer, called by him a Planetarium, in the construction of machines intended chiefly to exhibit the orbital motions of the planets. Roemer had also invented a satellite machine prior to the year 1679, the original or a copy of which was presented by him in that year to the English astronomer Flamsteed. Both his machines are described in his 'Basis Astronomiæ,' printed in 1735. The last machine we shall mention is the Planetarium of the Royal Institution of London, constructed about the year 1801, shortly after Dr. Garnett, having previously removed his apparatus elsewhere, discontinued his astronomical lectures at that institution. For a description of this machine, the plan of which was suggested by Dr. Young and the Rev. W. Pearson, we must again refer to the paper 'On Planetary Machines,' by the latter gentleman.

The chief part of every orrery is the mechanism composing the planetarium, by means of which the paths of the planets about the sun and their relative periodic times are exhibited with more or less approach to truth; and this mechanism, with the method of computing it, being once understood, it will be easy to extend the same principles to the more complex cases in which the satellites revolve about their primaries at the same time that the latter rotate upon their axes and revolve about the sun, as well as to those in which the parallelism of the planets' axes and the changes in the positions of their orbits, &c. are sought to be represented. For this reason we shall confine ourselves to the method of computing the wheel-work, which will give the relative periods with any required degree of accuracy, and to the explanation of a very ingenious contrivance by means of which a true elliptic orbit may be produced. Before however proceeding to this, we would caution the purchasers of these expensive toys (those exhibited in the shops of mathematical instrument makers vary in price from sixteen to fifty guineas) against a defect which was at one time not uncommon and may still exist, and which, while it rendered them worse than useless, showed how little knowledge their inventors could have possessed of the science they are intended to illustrate. We allude to the substitution of the synodic for the sidereal periods, whereby each planetary ball was made to revolve about the sun in the time which ought to have elapsed between two consecutive conjunctions of such planet with the earth.

To produce the revolution of the planetary balls about the sun, a system of vertical concentric tubes is usually employed, which are adjusted very near to each other, but yet so far removed as not to influence each other's motion. These tubes are of different lengths, the innermost being the longest, and to the superior extremity of each a radius vector is attached, and thereby made to revolve once during each revolution of the tube. The lower extremities of the tubes form the arbors or axes of as many toothed-wheels, which are either immediately driven by pinions adjusted to a vertical axle called the 'annual arbor,' or derive their motions indirectly from those pinions by means of an interposed train of wheels. The determination of the relative number of teeth which must be given to the wheels and pinions in order to produce any required motion may be thus explained.

A pinion generally means a wheel consisting of a less number of teeth than that which it drives, but in the present article this restriction is unnecessary. The teeth of a pinion are called leaves. The number of revolutions made by the wheel during one revolution of the pinion by which it is driven, is found by dividing the number of leaves in the pinion by the number of teeth in the wheel:—thus, if there be 28 leaves and 7 teeth, the wheel will make $\frac{28}{7}$ or 4 revolutions during one revolution of the pinion; but if there be 7 leaves and 35 teeth, the wheel will make $\frac{7}{35}$ or $\frac{1}{5}$ of a revolution during one entire revolution of the pinion. If to the axle of the wheel be adjusted a second pinion, which drives a second wheel, and if to the axle of this wheel a third pinion be adjusted which drives a third wheel, and so on, then the number of revolutions made by the last wheel during one revolution of the first pinion will be found by multiplying together the number of leaves in the several pinions, and dividing the result by the product of the number of teeth in the several wheels:—thus if there be four pinions, having 7, 8, 9, and 10 leaves respectively, and the same number of wheels, having 20, 21, 22, and 23 teeth respectively, the number of revolutions made by the last wheel during one revolution of the first pinion will be $\frac{7 \times 8 \times 9 \times 10}{20 \times 21 \times 22 \times 23} = \frac{6}{253}$, or, in other words, the last wheel will revolve six times during 253 revolutions of the first pinion. Conversely the ratio which the product of the number of leaves must bear to the product of the number of teeth, in order to produce any required relative motion between the first pinion and the last wheel, is found by dividing the number of revolutions made by the wheel by the number of revolutions to be made in the same time by the pinion. The actual number of teeth to be given to the wheels and pinions, as well as the number of wheels and pinions to be employed in any particular case, is matter of convenience, not of necessity: in every instance the employment of a single pinion and a single wheel is theoretically sufficient, but in practice it is generally desirable to avoid the use of wheels or pinions with a very large or very small number of teeth. In the planetarium of the Royal Institution the number of teeth is in no instance under 7, or above 137. In a more complete instrument, constructed by Dr. Pearson in 1812, the limits were 14 and 251. The same gentleman recommends about 10 teeth to the inch, which he considers 'sufficiently strong, and not liable to unnecessary shake, when the teeth and spaces are made equal and at a proper depth for action.' The lowest number employed by him was 7 to the inch, the highest 15.

Supposing we wish the radius which carries the ball representing the earth to revolve once during each revolution of the annual arbor, it is only necessary that the wheel which is adjusted to the lower extremity of the earth's tube should contain the same number of teeth as the pinion by which it is driven, and which is adjusted to the annual arbor. In this case each revolution of the annual arbor will be the measure of one solar year. If each revolution of the annual arbor be required to represent any assigned portion of a year, the necessary modification in the relative number of teeth in the earth's wheel and pinion will appear sufficiently obvious from what has preceded; but for the sake of simplicity, we shall assume that the earth's radius vector revolves exactly once during each revolution of the annual arbor, and upon this supposition we have now to fix the relative number of teeth which should be given to the wheels and pinions which regulate the motions of the other planetary balls. It generally happens that the number of revolutions which the radius vector of any one of the planetary balls is required to make during one revolution of the annual arbor is expressed in the form of a decimal. Suppose, for instance, that the relative motion required were that of the earth and Jupiter. Jupiter revolves in 4332·5848 mean solar days; the earth in 365·2564 mean solar days; the number of revolutions made by Jupiter during one revolution of the earth is therefore $\frac{365{\cdot}2564}{4332{\cdot}5848} = {\cdot}0843045$. If this decimal be converted into a continued fraction by the rule given at page 462, vol. x., the resulting series of fractions, which approximate more and more nearly to ·0843045, will be found to be $\frac{1}{11}$, $\frac{1}{12}$, $\frac{7}{83}$, $\frac{29}{344}$, $\frac{94}{1115}$, &c., any one of which, according to the degree of accuracy required, may be taken for the ratio which the number of leaves in the pinion must bear to the number of teeth in the wheel, if only a single wheel and pinion be employed, or the ratio which the product of the number of leaves must bear to the product of the number of teeth, if a train of wheels and pinions be employed. If the first of these fractions, or its equivalent, $\frac{7}{77}$, be taken, the wheel attached to Jupiter's tube should contain 77 teeth, and the pinion attached to the annual arbor by which it is driven should contain 7 leaves, and Jupiter's radius will then revolve once during 11 revolutions of the annual arbor, that is, in 365·2564 × 11 = 4017·8204 days, which is less than the true period by 314·7644 days. In the same manner may be found the time in which Jupiter's radius will revolve when any of the other fractions are taken, as under:—

$$\begin{array}{r} \text{days.} \\ 365{\cdot}2564 \times \end{array} \left\{ \begin{array}{lll} & \text{Period produced.} & \text{Error.} \\ & \quad\text{days.} & \quad\text{days.} \\ \frac{11}{1} & = 4017{\cdot}8204 & 314{\cdot}7644 - \\ \frac{12}{1} & = 4383{\cdot}0768 & 50{\cdot}4920 + \\ \frac{83}{7} & = 4330{\cdot}897 & 1{\cdot}688 - \\ \frac{344}{29} & = 4332{\cdot}699 & 0{\cdot}114 + \\ \frac{1115}{94} & = 4332{\cdot}562 & 0{\cdot}023 - \\ \&c. & \&c. & \&c. \end{array} \right.$$

The third of these fractions, or rather its equivalent, $\frac{166}{14}$, was the one employed by Dr. Pearson in the construction of his new planetarium; so that in that instrument the wheel attached to Jupiter's tube contains 166 teeth, and is driven by a pinion of 14 leaves attached to the annual arbor. In the planetarium of the Royal Institution, a train of wheels and pinions represented by the compound fraction $\frac{111}{22} \times \frac{94}{40}$ was employed, which therefore gives a period of $365{\cdot}2564 \times \frac{111}{22} \times \frac{94}{40} = 4330{\cdot}778$ days. The following table affords a general view of the wheel-work of the last-named instrument. The denominator of the former of the two fractions in the second column denotes the number of leaves in the pinion attached to the annual arbor; the numerator, the number of teeth in the wheel which it drives. The denominator of the second fraction denotes the number of leaves in the pinion attached to the axle of the last-mentioned wheel; the numerator, the number of teeth in the wheel driven by this pinion, which wheel is attached to the lower extremity of its appropriate planetary tube.

The planets Vesta and Juno had not been discovered at the time this machine was constructed.

The contrivance by means of which a true elliptic orbit may be produced is extremely simple. For this purpose all that is necessary is that the radius vector which connects the planetary ball with the superior extremity of the tube should consist of two parts or arms, the lengths of which have a determinate ratio dependent solely upon the eccentricity of the orbit, and that while the larger arm revolves about the *centre* of the ellipse by means of the wheel-work already described, the smaller arm be made to revolve about the extremity of the larger with the same angular velocity but in the opposite direction. This may be effected in two ways. By means of a pulley *fixed* to the planetary tube and connected by an endless silken cord with another pulley free to revolve about a vertical axle situated at the extremity of the larger arm. The effect of this connection will be that the latter pulley will revolve once during each revolution of the larger arm but in the opposite direction. If therefore the smaller arm be attached to this pulley it will revolve in the manner required. The same motion may be produced by employing a double pinion extending the entire length of the larger arm and communicating the rotatory motion given to it at one extremity, to the axle of the smaller arm situated at the other. Let R and r denote the lengths of the larger and smaller arms respectively, and let the line joining the position of the sun and the centre of the concentric tubes, considered as the origin of co-ordinates, be taken for the axis of x. The aphelion of the orbit will be the point $(R+r, o)$. Also let θ denote the inclination of the larger arm to the axis of x at any moment; then since the smaller arm revolves with the same angular velocity, but in the opposite direction, its inclination to the axis of x at that moment must be denoted by $-\theta$; and the coordinates of the extremity of the smaller arm, that is, of the position of the planetary ball, will be the sum of the projections of R and r upon the axes of x and y respectively. Representing these co-ordinates by x and y, we shall therefore have

$$x=R\cos\theta+r\cos\theta=(R+r)\cos\theta$$
$$y=R\sin\theta-r\sin\theta=(R-r)\sin\theta;$$

and eliminating θ between these equations, there results

$$\frac{x^2}{(R+r)^2}+\frac{y^2}{(R-r)^2}=1,$$

which is the well-known equation to an ellipse referred to its centre, and whose semi-focal and non-focal axes are respectively $R+r$ and $R-r$. If the excentricity e of the orbit be known the relation between R and r will therefore be determined by the equation

$$e=\frac{2\sqrt{R.r}}{R+r.}$$

The distance E, between the position of the ball representing the sun and the common centre of the tubes is expressed by

$$E=2\sqrt{R.r}.$$

This method is defective in two respects. The elliptic orbits described cannot have a common focus, or else the true relative lengths of the mean distances of the planets cannot be preserved; and secondly the true angular motions of the planets about the sun are not accurately represented. Dr. Pearson corrected in some degree the latter inequality by varying the size of the teeth of the wheels and pinions employed, but for the mere purpose of illustration this appears superfluous, since, after all, the most complete mechanical representation of the solar system that has yet been invented is far inferior to that which the student may form in his own mind from an attentive perusal of a good popular treatise upon the subject.

ORRERY, EARL OF. [BOYLE.]

ORSI'NI, an old and illustrious family of Southern Italy, which has had among its members several popes, many cardinals, and other distinguished individuals. Orso Orsini, of Petigliano near the lake of Bolsena, is mentioned as senator of Rome in the years 1190-1200. His son Giovanni Orsini Gaetani, which last was his mother's family name, left two sons: 1, Napoleone Orsini, Count of Tagliacozzo in the kingdom of Naples; and 2, Matteo, styled 'the Great,' senator of Rome, and lord of Anagni, Marino, Galera, and other fiefs in the Campagna of Rome. Matteo left several sons, one of whom, Giovanni Gaetani, became pope under the name of NICHOLAS III. A branch of the family entered the service of the Anjou kings of Naples, obtained high honours at that court, and the titles of counts of Nola and dukes of Gravina. The Orsini who remained in the Papal State were often at variance with the powerful family of COLONNA during the middle ages. The castle of Bracciano, on the lake of that name, was the chief residence of the Orsini. In January, 1505, Francis Orsini, duke of Gravina, and Paolo Orsini, were treacherously seized and strangled at Sinegaglia by Cesare Borgia, whilst the cardinal Orsini was poisoned at Rome by order of Cesare's father, Pope Alexander VI. By degrees the various branches of the Orsini became extinct, and their estates passed into other hands, with the exception of the Neapolitan branch of the dukes of Gravina, which still continues, the actual duke having married a daughter of the banker Torlonia, duke of Bracciano. The palace Orsini at Rome, a vast building, stands on the ruins of the Theatre of Marcellus. The family palace at Naples, belonging to the duke of Gravina, is one of the finest private buildings in that capital. (Imhoff, *Genealogies*; Moreri; *Almanach de Gotha.*)

ORSI'NI, FULVIO, said to have been an illegitimate member of the noble family of that name, was born at Rome about 1530, and became canon of St. John of Lateran. He was well versed in classical literature, both Greek and Roman, and collected a valuable library of MSS., which he bequeathed to the Vatican library. He was intimate with the cardinals Alexander and Edward Farnese, and was considered one of the first scholars of his age. He died at Rome, about the year 1600. He wrote several learned works: 1, 'Familiæ Romanæ quæ reperiuntur in antiquis Numismatibus, ab Urbe Condita ad tempora Divi Augusti, cum adjunctis Antonii Augustini Episcopi Ilerdensis,' fol., Paris, 1663; 2, 'Virgilius collatione Scriptorum Græcorum illustratus,' in which he points out the numerous passages in which Virgil has imitated or borrowed from the Greek poets; a very interesting commentary; 3, 'Selecta de Legationibus ex Polybio et Fragmenta ex Historiis quæ non extant Dionysii Halicarnassei, Diodori Siculi, Appiani Alexandrini, Dionis Cassii, &c.,' 4to., Antwerp, 1582, in Greek, with Latin notes, 4to.; 'Carmina novem illustrium Fœminarum Græcarum,' 8vo., Antwerp, 1568, and other minor publications.

---

* The oversight alluded to in p. 39, that of mistaking the synodic for the sidereal period, does not appear to have been altogether avoided in the construction of the planetarium of the Royal Institution, the wheel-work of which is computed on the supposition that the earth completes its revolution about the sun in 365·242 days. This is the length of the *tropical* year, or the time which elapses between the earth's leaving the vernal equinox and its arrival again at that point of the ecliptic; and is, owing to the precession of the equinoxes, less than the earth's sidereal period.

† In the descriptions of the planetarium of the Royal Institution, to which we have been able to refer, the wheel-work of Saturn is represented by $\frac{127}{7}\times\frac{98}{59}$, and that of the sun by $\frac{19}{137}\times\frac{25}{62}$. The former would produce a period of 11007·22 days, the latter of 4·92 days. We have little doubt that the numbers we have substituted for 127 and 62 are those which were actually employed. It is necessary to observe that the train for producing the sun's rotation derives its motion directly from Mercury's tube, to which the first pinion of the train, ted by the number 137, is attached, thereby producing a period of $\frac{19}{137}\times$

days. days.
$\times 87\cdot972=25\cdot418$.

ORTA'LIDA. [Chalcides, vol. viii., p. 191.]

ORTE'LIUS, ABRAHAM, born at Antwerp in 1527, of a family originally from Augsburg, studied philology and mathematics, and became the first geographer of his age. After travelling through England, Germany, France, and Italy, he published his great work, 'Theatrum Orbis Terræ,' being a description of the globe, or universal geography. He was soon after appointed geographer to Philip II. of Spain. His other works are—1, 'Deorum Dearumque Capita ex veteribus Numismatibus;' 2, 'Aurei Sæculi Imago, sive Germanorum Veterum Mores, Vita, Ritus, et Religio;' 3, 'Itinerarium per nonnullas Galliæ Belgicæ Partes.' Ortelius was acquainted with most of the learned men of his age, and was particularly intimate with Justus Lipsius, who wrote his epitaph. He died in 1598. (*Sweert's Vita Ortelii*; Valere Andre, *Bibliotheca Belgica*.)

ORTHE'S, or **ORTHEZ,** a town in France, capital of an arrondissement in the department of Basses Pyrénées, 509 miles from Paris, on the road by Poitiers, Bordeaux, and Mont de Marsan to St. Jean Pied de Port and Pamplona in Spain, and at the intersection of a cross-road from Bayonne to Pau. The town is pleasantly situated on the right bank of the Gave de Pau, which flows between steep banks of limestone. There is a suburb on the left bank, which communicates with the town by an antient Gothic bridge. On the only pier of this bridge is a tower. The streets of the town are well laid out, and the houses tolerably well built. There are some ruins of the antient castle of Moncade, on a height commanding the town. The population of Orthès, in 1831, was 5102 for the town, or 7121 for the whole commune; in 1836, it was 7857 for the commune. The townsmen carry on trade in salt provisions, especially hams. The manufacture of linen, especially of table-linen, flourished formerly, but has much declined; that of woollen stuffs and some hardwares is carried on. There are tanyards and currying-shops. The market for cattle and corn is considerable, and there are two large yearly fairs. Slate and coal are quarried in the neighbourhood, and sulphur and petroleum are procured. Six roads converge at the town.

This town was antiently subject to the viscounts of Dax, then to the princes of Béarn. Jeanne d'Albert, queen of Navarre, founded here a university for the Protestants, who then predominated in the town, and who still form a fourth or a third part of the inhabitants. They have a church; and there are a Bible Society, a high school, and several government offices.

A severe action was fought near this town 27th February, 1814, between the allied forces under the Duke of Wellington and the French under Marshal Soult. The French were strongly posted on the right of the Gave de Pau; but the Duke of Wellington, having brought seven divisions of British and Portuguese infantry and two brigades of cavalry to bear on the position of the French, dislodged them from all their posts, and obliged them to retreat. The French suffered great loss in killed and by desertion; the loss of the British was about 2300. (Duke of Wellington's *Despatches*.) Some French writers, as Malte Brun and Vaysse de Villiers, have given a very exaggerated statement of the number and the loss of the allies.

The arrondissement of Orthès contains 152 communes, and comprehends an area of 424 square miles; it is subdivided into seven cantons or districts, each under a justice of the peace. The population in 1831 was 84,667; in 1836, 87,459.

ORTHITE. *Silicate of Cerium, Iron,* &c. This mineral occurs in minute, slender, columnar imbedded masses. Fracture conchoidal; hardness 6·0, 7·0. Colour grey, inclining to black. Streak brownish grey. Lustre vitreous. Opaque. Specific gravity 3·288.

Before the blow-pipe swells and fuses into a blackish globule; with borax it gives a transparent glass. Gelatinises in acids and yields a solution of cerium.

It is found at Finbo, near Fahlun in Sweden, and also in Greenland, &c.

Analysis of the mineral from Finbo, by Berzelius:—

Silica	36·25	
Protoxide of Cerium	17·39	
Protoxide of Iron	11·42	
Alumina	14·00	
Lime	4·89	
Yttria	3·80	
Oxide of Manganese	1·36	
Water	8·70	
		97·81

ORTHOCE'RAS. [Polythalamacea.]

ORTHOGONAL. ORTHOGRAPHIC. The first of these terms, when not used in the same sense as the second, means simply perpendicular. Thus a curve cuts a set of curves orthogonally when it cuts them all at right angles.

Orthogonal or orthographic projection is that which is made by drawing lines from every point to be projected, perpendicular to a plane of projection. Thus if a plane were horizontal, and a point were to drop from a given position upon the plane, its last position would be the orthogonal or orthographic projection of its first. [Perspective.]

ORTHOGRAPHY. When this word is looked at in its elements (two Greek words denoting *the art of writing* and *correctness*), it would seem that there ought to be included under it whatever belongs to the art of writing a language correctly, including both what is called etymology and syntax. But the grammarians have given it a restricted sense, and it is used to denote not the writing correctly in the general, but the proper selection of literal elements of each word that is used, and the proper division of each word when one part of it is at the end of one line and another at the beginning of the line which succeeds. In the antient Hebrew manuscripts we may observe that this division of words never occurs, the scribes resorting to the expedient of widening certain of the letters, if in the ordinary form the words would not fill up the line. The law-stationers in their copies of legal documents fill up a line with a waved and unmeaning stroke, when the word which follows cannot conveniently be written in it at length.

We perceive by certain grammars and dictionaries published by practical men, both at home and still more in the United States of North America, that the writers appear to suppose that their works will be resorted to even by persons of cultivation as authorities or guides to orthography. But we believe it to be the case that the number is very few of persons who actually use dictionaries for this purpose. We mean of course not mere children or persons of very imperfect education, but even of those there are very few persons who read much and write occasionally, who ever think of resorting to books of the kind we are speaking of; and persons of a better education still trust entirely to memory, and should a doubt arise, the reference would be made to some eminent author and not to the guides of which we speak. In fact, the art is acquired almost without teaching, and is maintained in vigour through a whole life by the constant practice of writing and reading. At all events there is no book, grammar, guide, or dictionary, which a scholar in England regards as in this point a book of any authority.

Whether it would be expedient to raise some one work into an authority in such a point as this, is in fact a question —one of the greatest in philology that can be proposed— whether there shall be an invariable standard established to which a living language shall for ever conform. We doubt not only the possibility but the expediency of this: and in respect of orthography, we are quite sure that no such standard can be raised, because it would be quite impracticable to bring all persons who have a right to a voice in such a matter to an agreement in any one system involving the admission of certain fixed principles. The contemporary usage of persons of cultivation, meaning of a great preponderating majority, which will always exist, is, we apprehend, the authority to which each person who aspires to write correctly must continue to defer.

This has been the standard to which reference has always hitherto been made. Open any book printed in the reign of Queen Anne, and many words will present themselves in an orthography very different from that in which they would now be found. But we must not say that the persons who wrote them wrote incorrectly, if they wrote according to the practice of the cultivated persons of their time. If we ascend still higher and go to the reign of Elizabeth, we find the orthography still more diverse from our own; and when we reach the time of Caxton, and still more when we go back to the time of Chaucer and Wickliffe, we find many words which, though they are actually words now in use, are so disguised in their orthographical form that we can scarcely recognise them. We seem to have got among a people who spoke a different language, though they were our own forefathers, not more than ten or twelve generations above our grandfathers.

This has arisen from the want of a standard; something fixed, not varying like usage. There is an inconvenience in it as respects the writers before the time of Caxton and the invention of printing, and we may reasonably wish that with reference to them there had been some less varying standard and a continuous uniformity; but when we look in the writings of the men of the Elizabethan period, we find that though now two centuries and a half have passed, there is no more difficulty in perusing them than there is in perusing the writings of our own day; and that the same will be the case in respect of the writings of the present day in the hands of Englishmen four or five centuries hence, may be safely foretold. So that there is no real prejudice arising from the apparently unphilosophical and dangerous course of leaving this point to be regulated by anything so uncertain as contemporary usage.

At present the number of words of which the orthography is not uniform in all writings which aspire at once to be correct and devoid of affectation, is exceedingly small. Take this sentence and the whole of the paragraph which precedes it; is there any word, except this word *precede*, in which any variety would be found in the ordinary current writings of the day? Or if we found a variety, should we not say that the deviation from the usual practice was a casual mistake, a slip of the press, an affectation, or that it was the result of some peculiar principle which some peculiar person had adopted? And even this word *precede*, though it belongs to a class in which orthography is not uniform, we should probably very rarely find written in any other way, for few persons would prefer the form *preceed*, if indeed such a form is ever used. So that practically a great and perhaps quite sufficient degree of uniformity and stability may be said to be secured under the regulating power which now exists.

Dictionaries and vocabularies, as affording an easy guide to the knowledge of what is the usage, may have their use in this respect to a few persons who write occasionally only; but as authorities, we repeat, they are of no avail.

It has been matter of complaint that the orthography of the English language is not more uniform; that is, that words which are composed in whole or in part of the same elements are not uniform in the manner in which those elements are exhibited. Thus all words derived of the Latin *cedo* with prepositions prefixed, it may be said should be in one form, and it is a variety in defence of which nothing can well be pleaded that we should write *proceed* and yet write also *concede*. So with respect to such words as *honour*, *favour*, *odour*, *labour*, it may be said that there should be uniformity with other words like them, in which the *u* is not found, and further, that we should keep to the orthography of the Latin words of which they are forms equally in meaning and orthography. This appears plausible, but when it is considered that these words do not come to us *immediately* from the Latin, but have passed to us through the French, we recognise in the unnecessary letter *u* a part of the history of the word, which a person of true taste would scarcely be willing to relinquish for an advantage so trivial. Or take the rough word *through*: some may think that the three last letters may well be dispensed with, but they remain a pleasing evidence of the origin of the word in the rough and strong speech of our Saxon ancestors.

These little irregularities in orthography, like irregularities in other parts of grammar, are not to be regarded as evils. Such irregularities give birth to what are called *idioms*, in which no small part of the beauty of a language lies.

Attempts have however been made by ingenious men to introduce a greater degree of uniformity into our orthography. There is a treatise on the management of bees, printed about two centuries ago, in which we have a peculiar orthography on a system of the author's own. Ritson, in the last century, in some of his works adopted an orthography of his own. Professed writers on grammar have done the same; some of them to such an extent that the language, as written by them, can scarcely be known to be English. A more moderate reform is attempted by an American writer, Dr. Noah Webster, the author of an English Dictionary, which has been reprinted in this country; and Mr. Bromby of Hull, a learned and ingenious clergyman, has printed for private circulation a translation of the treatise of Plutarch concerning music, in which the orthography is regulated by certain principles which he lays down in the preface. But no writer who has made such an attempt has ever gained in any way the slightest share of public attention. Practically the usage is thought or found to be sufficient.

There is one point to which persons who take this view of the subject do not seem sufficiently to attend, and that is, the havock which any material changes in our orthography, so as to reduce it to some one system, would make in that beautiful poetry by which our language is ennobled, and which will preserve it at once from extinction and from any very material changes.

The words are in reality very few of which the orthography may not be said to be now *established* by the great *Jus et Norma Loquendi*, Custom. We take the following from a modern grammar, as being those which, in the opinion of the writer, are most frequently found with orthographical varieties:—

honour	honor
inquirer	enquirer
negotiate	negociate
control	controul
expense	expence
allege	alledge
complete	compleat
connexion	connection
abridgment	abridgement
surprise	surprize

Of course some of these represent classes. But what are these to the great body of such a language as ours? And with respect to the first and to the last, each of which represents a large family of words, we would submit that very few persons indeed who were entitled to a voice in a question of this kind would be found writing *honor*; and that there is a most excellent rule by which we imagine all persons of education allow themselves to be guided respecting words in *ise* or *ize*. The rule is this: when the word is a derivative of the French *prendre*, as is the case with *surprise*, *enterprise*, and one or two others, to write it with the *ise*; but when it comes to us from the Greek, as in *agonize*, and several other words, to keep the Greek termination ιζω—*Anglicè*, *ize*.

O'RTHONYX, M. Temminck's name for a genus of birds arranged by Mr. Swainson with *Buphaga* under *Buphaginæ*; these two genera forming the whole of that subfamily.

Generic Character.—*Bill* very short, straight, but the culmen arched from the base; sides considerably compressed. *Nostrils* large, basal. *Wings* moderate, but considerably rounded; the four first *quills* graduated, and shorter than the fifth. *Tail* rather lengthened, rounded; the feathers very broad, and the webs soft, but the shafts stiff, very rigid, and terminating in naked points. *Feet* enormously large and strong. The outer toe rather longer than the middle, which is again longer than the inner toe; hinder toe shorter than the middle. Tarsus longer than either of the toes. Claws strong, very slightly curved; the anterior all of the same length; the hinder one longest. (Sw.)

Geographical Distribution.—Australia only. (Sw.)

Example, *Orthonyx Spinicaudus*, Temm. *Orthonyx Temminckii*, Vig. and Horsf.

Description.—Rufous brown above, lineated with black; lesser coverts of the wings grey, streaked with brown; plumes of the top of the head slightly prolonged into a sort of false crest, which is however but little apparent: tail rounded, of a tarnished brown colour, each feather-stem terminated by a point furnished with small stiff bristle-like appendages. A bright orange patch covers the breast of the male, which part is white in the female.

Locality.—M. Lesson states that this bird is said to be a native of New Zealand. The specimen in the museum of the Linnean Society of London was presented by Mr. Brown, who met with it near Hat Hill in 1804.

Messrs. Vigors and Horsfield speak of this genus (*Linn. Trans.*, vol. xv.), which consists of the single species above noticed, as holding the same place in Australia as the true *Certhia* fills in the antient continent, and the numerous group of *Dendrocolaptes*, Herm., in South America. They observe that it possesses the strong and lengthened shafts of the tail-feathers which support the typical scansorial birds in climbing, and that it immediately connects the whole group by a strong affinity to the woodpeckers.

Mr. Swainson (*Classification of Birds*, vol. ii.), having described the foot of *Sclerurus*, the rasorial genus, in his opinion, of the circle of *Certhianæ*, refers to *Orthonyx* as the next modification. He describes the bird as rather larger than a sparrow, but with the general form and proportions of *Menura*, except in the tail. Like *Menura*, the

63). Its tail, however, is short, arched, and rasorial; the wings rounded, and the feet enormously large and strong. He notices the relative length of the toes as altogether peculiar, the outer one being equally longer (in a slight degree) than the middle one, while the two other claws, which are unusually straight in their curvature, are one-third as long as the toes; the hallux he describes as long as the middle toe, but having one-half its length occupied by the claw. Mr. Swainson thinks it quite obvious that claws so constructed were never intended to be used for ascending trees, and yet the rigidity of the tail would imply that this singular bird feeds in a perpendicular attitude, otherwise such a tail would be useless. The specimen before him when he wrote confirmed this supposition, for the ends of the feathers, or rather the shafts, were much worn away; and he conjectures, in the absence of information on the subject, that the habits of *Orthonyx* are terrestrial, that it is essentially a walking bird, but that it seeks its food not so much upon the bark of trees, as upon damp earthy banks, into which its unusually straight claws would penetrate, and against which the bird might be supported by its tail; and he thinks it also highly probable that these strong claws are used for scratching the ground, after the manner of rasorial birds. At all events he considers that the discovery of [illegible] establishes a link between *Dendrocolaptes* and *Orthonyx*, and he thinks that both are types of the *Rasores*, the one in the circle of the *Certhianæ*, the other in that of the [illegible].

[illegible]

[illegible]

ORTHOPTERA, one of the orders into which Insects are divided. This order, of which we have familiar examples in the common cockroach (*Blatta*), the house-cricket, and the grasshopper, is distinguished by the following characters: The superior wings are semi-coriaceous, usually displaying numerous nervures in a longitudinal direction, and having the interspaces filled up with transverse, or reticulated, smaller nervures: the anterior portion of the inferior wings is generally of a different substance from the posterior portion, the nervures are more crowded, and in character, and often even in colour, it nearly resembles the anterior pair of wings; the hinder portion of these wings is almost always more transparent, and, when not in use, is folded like a fan. The superior wings often overlap horizontally, as in the cockroaches, but in many species they meet at an angle like the roof of a house, as in the grasshoppers and locusts. The legs in some are formed for running; in others, the hinder pair of legs are very long and the thighs of these legs are thick, and in fact formed for leaping. The antennæ do not vary much; they are usually filiform; in many, extremely long and slender, in which case they are composed of innumerable minute joints; in others, they are shorter and thicker, and the joints are less numerous and consequently more distinct. The parts of the mouth are well developed and approach in structure those of the order Coleoptera; they are usually however less firm and compact, especially the labial apparatus. The upper portion of the prothorax is generally very large. The metamorphosis of the Orthoptera is semi-complete, that is to say, the larvæ and pupæ resemble the perfect insect, excepting that in the larvæ there are no wings, and in the pupæ the wings are in a rudimentary state. Some species however in the perfect state are wingless, in which case it is extremely difficult, and perhaps impossible, to distinguish the perfect insect from the pupæ or even the larvæ.

Latreille divides the order *Orthoptera* into two sections, to which he applies the names *Cursoria* and *Saltatoria*, or runners and jumpers. In the *Cursoria* all the legs are usually alike and fitted for running, and they are thus easily distinguished from the *Saltatoria*, in which the hinder legs are long and the thighs thick. The males of the species belonging to the second section have the power of producing a shrill noise, but this is not always effected in the same manner.

To the section *Cursoria* belong the families *Forficulidæ* (or Earwigs), the *Blattidæ* (Cockroaches), the *Mantidæ* (or Mantis tribe), and the *Phasmidæ*. The section *Cursoria* may be divided into three families—the *Gryllidæ* (of which the common House-Cricket affords an example), the *Locustidæ* (Locusts), and the *Acridiidæ* (or Grasshoppers).

The principal characters of these families are given under the proper heads; they may be distinguished by the following characters:—

A. Tarsi 3-jointed.	
a. Abdomen furnished with a forceps-like appendage	*Forficulidæ*.
b. Abdomen without forceps.	
* Antennæ filiform or prismatic .	*Acridiidæ*.
** Antennæ very long and setaceous	*Gryllidæ*.
B. Tarsi 4-jointed, antennæ setaceous .	*Locustidæ*.
C. Tarsi 5-jointed*.	
a. The prothorax the longest of the three thoracic segments . .	*Mantidæ*.
b. The prothorax the shortest of the three thoracic segments . .	*Phasmidæ*
c. The prothorax broad, more or less rounded, and generally covering the head	*Blattidæ*.

ORTHORHYNCHUS. [TROCHILIDÆ.]

ORTHOTOMUS. [SYLVIADÆ.]

ORTOLAN, the French and English names for a species of *Fringillidæ*, much esteemed by epicures for the delicacy of its flesh when in season. It is the *Hortulanus* of Gesner and others, *Miliaria pinguescens* of Frisch, *Emberiza hortulana* of Linnæus, *Ortolano* of the Italians generally, *Tordino Berluccio* of the Venetians, *Garten Ammer* and *Fettammer* of the Germans, and *Gerste Kneu* of the Netherlanders. Willughby writes the name *Hortulane;* and Montagu terms it the *Green-headed Bunting.*

---

* In one genus which is placed in this family ([illegible]) the posterior tarsi have only three joints.

Description.—Male. Throat, circle round the eyes, and a narrow band springing from the angle of the bill, yellow; these two yellow spaces being separated by a blackish grey dash; head and neck grey, with a tinge of olive and small brown spots; feathers of the upper parts reddish on their edges and black in the middle; breast, belly, and abdomen reddish bay, all the feathers of those parts being terminated with ash-colour; tail blackish, a considerable portion of the two external feathers white on their internal barbs; bill and feet inclining to flesh-colour; iris brown. Length rather more than six inches.

Female smaller; band above the eyes and throat pale yellow; breast marked with large brown spots; the other parts below of a whitish rust-colour; a number of brown spots on the head and neck; all the upper parts less deep in colour than in the male.

Young before the first moult.—The yellow on the throat but slightly visible and tinged with greyish.

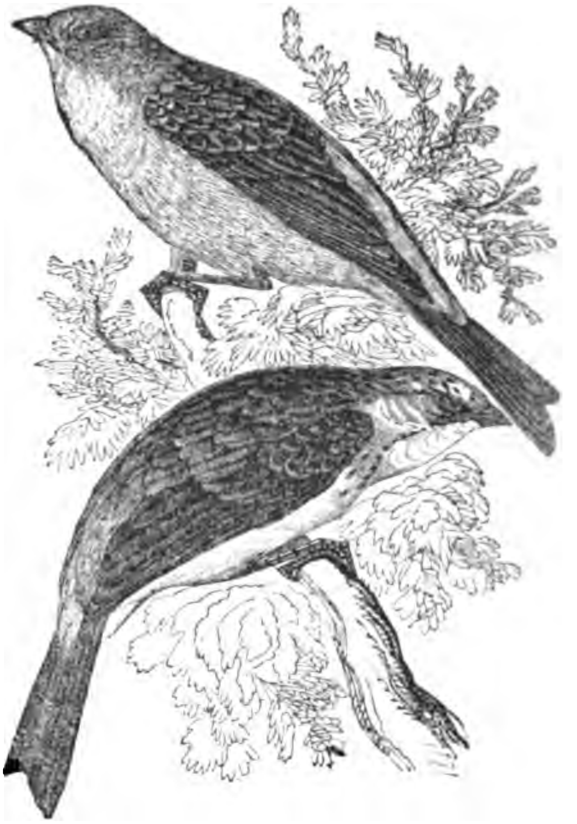
Varieties.—Pure white. The body partially white or whitish, or simply flecked with white; *Ortolan blanc* of Buffon. Other varieties (M. Vieillot enumerates six, one of which, variety C, has the head and neck green) are recorded; the *Emberiza Malbeyensis*, Sparrm., *Bruant de Malby*, Sonn., for example. In many the colours are deeper, and in some blackish or entirely black, apparently from the quality of the food, as when the bird has been fed with hemp-seed.

Food.—Millet and other farinaceous grain · insects, especially in the early part of the season before the grain is ripe.

Reproduction, Habits, &c.—The nest, which is constructed of fibres of plants and leaves, lined generally with fine grass and hairs, is very frequently found on the ground in corn-fields; though, according to circumstances, the bird varies its site, and it is placed also in hedges or bushes. The eggs, four or five in number, are reddish-grey streaked with brown; or bluish-white speckled and spotted with black. It haunts bushy places, or those situations where hedges abound.

Geographical Distribution.—The south of Europe may be considered the summer and autumnal head-quarters of the Ortolan, though it is a summer visitor in the central and northern parts. In Italy it is said to be common by Temminck and others. The Prince of Musignano states that it is found in the Sabine Mountains, but not commonly, in the summer, and that it rarely occurs in the plain of Rome, but that it is frequent in Tuscany. Lapland, Russia, Denmark, Sweden, and Norway are among the countries visited by it. In these islands it seems to be only entitled to rank as an accidental visitor, but it is by no means clear that it does not occur more frequently than is generally supposed; for, especially to an unpractised eye, it might be mistaken for the yellow-hammer, and in some states of its plumage for other Buntings. It has been taken in the neighbourhood of London; and one of these specimens was alive in 1837, in the aviary of the Zoological Society in the Regent's Park. Bewick's figure (*Green-headed Bunting*, last edition, Supp., p. 24) was captured at sea off the Yorkshire coast, in May, 1822. In Southern Europe it is common from May to August, and every spring and autumn may be observed at Gibraltar on its migration. Mr. Strickland saw it at Smyrna in April. North Africa is its winter residence. Colonel Sykes notes it in his Catalogue of the Birds of Dukhun (Deccan).

Utility to Man.—When properly fed, for which purpose there are large establishments in the south of Europe, where they are placed after having been trapped and furnished with plenty of millet-seed and other grain, till they become sheer lumps of fat, they are delicious morsels. Mr. Gould states that this is effected in Italy and the south of France in a *dark* room. The Prince of Musignano says, 'Nella vicina Toscana, dove gli *Ortolani* sono frequenti, si tengono nelle Uccelliere *illuminate giorno e notte* finche restano soffocati dalle pinguedine;' and he adds the following words, 'Carne squisita.'



Ortolan

Upper figure, male; lower figure, female. (Gould.)

O'RTYGIS. [Tetraonidæ.]

ORTYX. [Tetraonidæ.]

ORUS, or HORUS, an Egyptian deity, the son of Isis and Osiris, corresponds, according to Herodotus, to the Apollo of the Greeks, and was the last of the gods who reigned in Egypt. (Herod., ii. 144; Diod., i. 44.) Typhon, after the murder of his brother Osiris, sought to kill Orus; but his mother Isis, according to Herodotus (ii. 156), committed him to the care of Leto, who brought him up in the moving island of Chemmis, which was in the lake Buto. The Egyptian priests however in this instance, as well as in many others, appear to have been anxious to assimilate the history of their deities as much as possible to that of the Greeks. When Orus had grown up, he is said to have made war upon Typhon, whom he deprived of the kingdom of Egypt, and, according to some accounts, put to death. (Diod., i. 25; Herod., ii. 144; Plutarch, *De Is. et Osir.*, p. 358, Francfort, 1620.)

According to Diodorus (i. 25), Orus was killed by the Titans, and restored to life by his mother Isis, who conferred upon him immortality, and taught him divination and the healing art.

Orus is frequently represented as sitting in the lap of Isis. He appears also to be represented in some bronzes in the British Museum, which depict a man trampling on the crocodile, since we know that the crocodile was one of the symbols of Typhon. (*Egyptian Antiquities*, 12mo., Lond., 1836, vol. ii., p. 306.)

A work on Egyptian hieroglyphics has come down to us purporting to be written by Orus, or Horus, of which an account is given in the article Horapollo.

ORVET, the French name for the *Blindworm* (*Anguis fragilis* of Linnæus). [Blindworm.]

MM. Duméril and Bibron, who, in their recently published work ('Histoire des Reptiles,' tome v., 1839), place the form among the *Scincoidean Lizards*, and next to *Ophiodes*, state that up to the time of their publication all authors have denied an external auditory opening to the *Anguis fragilis*, Linn., whereas this Scincoidean has one, very small it is true, but distinct nevertheless when pains are taken to search for it, even without the aid of a lens. They state that this orifice, which is linear, and from one to two millimetres in length, is situated behind the commis sure of the lips at a distance equal to the length of the muzzle; sometimes it is uncovered, sometimes it is hidden under the scales; and in the latter case they must be raised before it is perceptible.

Mr. Bell, in his 'History of British Reptiles' (1839), places the form among the *Saurophidia* of Mr. Gray, and makes 'tympanum concealed' a part of the generic character. The former English zoologist remarks that the group to which the genus *Anguis* belongs (meaning of course as it is at present confined, namely, to the single species known vulgarly as the *Blindworm*, for the Linnean genus *Anguis* had a much wider range) is one of the most interesting in its relations of all the forms of the *Reptilia*. 'Under external characters considerably differing from each other,' says Mr. Bell, 'some possessing the limbs and integument of true lizards, and others wholly devoid of external members, and moving like true serpents, there are (in Mr. Gray's order *Saurophidia*) many points of mutual affinity which prevent the possibility of separating them from each other. From the well known families of the Skinks, or *Scincidæ*, with their true legs and five-toed feet, down to the present species and its immediate congeners, every possible gradation is to be found in the development of the anterior and posterior extremities. Agreeing, as they all do, in the Saurian character of the structure of the head, the consolidation of the bones of the cranium and face and the narrow and confined gape, so different from these parts in the true serpents, they yet approach the latter in the comparative length of the bodies, and in the gradual diminution and ultimate disappearance of the extremities.'

Mr. George Daniel, who kept a very fine Blindworm alive for nine weeks, found that when touched it would bite, though not sharply enough to draw blood, keeping its hold however till it was released. It drank sparingly of milk, raised the head when drinking, and fed upon the little white garden slug (*Limax agrestis*, Linn.), swallowing six or seven in succession; but it did not feed every day. Elevating its head slowly above the slug, the Blindworm suddenly seized it by the middle, held it thus sometimes more than a minute, then passed it through the jaws, and swallowed it head first. It refused larger slugs, young frogs, and insects; but snakes kept in the same cage took both frogs and mice. The Blindworm avoided the water, the snakes sought the pan in which it was kept, coiled themselves up there, and appeared to delight in it. When it cast its slough, the skin came off in separate pieces, splitting first on the belly, and that of the head peeled off last; the largest piece was two inches in length. (Note to Bennett's White's *Selborne*.)

Mr. Bell is of opinion that Blindworms in a state of nature do not live upon slugs exclusively; he found the remains of insects in the stomach, and adds that they will feed readily on earthworms six or seven inches long; but he denies that they can swallow small rats, mice, toads, and frogs.

The Blindworm is *ovoviviparous*, the eggs being hatched internally, and the young excluded alive. They are from seven to twelve or thirteen in number, and are produced in June or July, being each from 18 to 22 lines in length.

Mr. Swainson (*Natural History of Fishes, Amphibians, and Reptiles*, 1839) places the *Anguidæ* under the order of Serpents between the *Colubridæ* and the *Amphisbænidæ*, making the *Anguidæ* consist of the genus *Pseudopus*, *Ophisaurus*, *Anguis*, and the subgenus *Acontias*.

ORVIE'TO, ORIVETO, a town of the Papal State and a bishop's see, in the province of Viterbo, is built on a steep hill 1200 feet high, which rises above the river Paglia, an affluent of the Tiber; it is about sixteen miles north-east of Viterbo. The hill of Orvieto is of volcanic formation, and is detached from the calcareous ridge which divides the basin of the lake of Bolsena from the valley of the Tiber. The town contains 6000 inhabitants. (Calindri, *Saggio Statistico dello Stato Pontificio*.) It is chiefly remarkable for its handsome Gothic cathedral, begun towards the end of the thirteenth century, and finished towards the middle of the fourteenth. The façade, one of the finest in Italy, is ornamented with sculptures and mosaics. (Della Valle, *Stampe del Duomo rappresentanti il Duomo di Orvieto*, Rome, 1791.) One chapel, dedicated to the Virgin Mary, is painted by Luca Signorelli, who has represented the Judgment, Hell, and Paradise, with a curious mixture of heathen mythology and Christian imagery. The other chapel, which contains the corporal said to have been stained by the bleeding host at Bolsena, is very rich. [BOLSENA.] The other remarkable buildings of Orvieto are the town-house and the Jesuits' college, and a very deep well, excavated in the tufa rock on which the town is built, with steps to the bottom. The country around Orvieto is fertile, and produces a kind of delicate white wine, which is in great repute at Rome.

Orvieto appears to have no well founded claim to classical antiquity, though some antiquarians have pretended that it is the same as Oropitum, a town of the antient Etruscans, of which nothing more than the name is known. Orvieto was called Urbs Vetus in the time of the Longobards, and is mentioned by Paulus Diaconus, and by pope Gregory I. (Della Valle, *Storia del Duomo di Orvieto*, 4to., Rome, 1791.)

ORY'CTEROPUS. [AARD-VARK.]

ORY'CTERUS. [MURIDÆ, vol. xv., p. 516.]

ORYX. [ANTELOPE, vol. ii., p. 67.]

ORY'ZA, the name by which rice was known to the Greeks and Romans, and which has been adopted by botanists as the generic name of the plant yielding that valuable grain. The Greek name would appear to be derived from the Arabic *Aruz*, and this is allied to *Uri*, the Telinga name of cultivated sorts; but the Sanscrit names are *Vrihi*, *Dhanya*, *Vrihi*; the wild kind being called *Nivara*, while the great tanks are called *eraya* in the Tamul language. The European names are evidently all derived from the same sources, but the name *paddy* is applied to the rice in its natural state, or before being separated from the husk. The natives of India call it *dhan* in this state, as well as the plant, and the rice itself is called *chawul*.

The genus *Oryza* has two glumes to a single flower; paleæ two, nearly equal, adhering to the seed; stamens six, and styles two. Dr. Roxburgh describes two species: one, *O. sativa*, distinguished by its diffuse panicle; the other, *O. coarctata*, has the panicle contracted, the valvulets of the calyx subulate, and the leaves culm-clasping. This species is a native of the delta of the Ganges, and was first discovered there by Dr. Buchanan in 1796, but was not found to be applied to any use.

The common rice, *Oryza sativa*, unlike many long cultivated grains, is still found in a wild state in and about the borders of lakes in the Rajahmundy Circars, though never cultivated, because the produce is said to be small compared with that of the varieties in cultivation. The grain is however remarkably white, palatable, and reckoned very wholesome; hence it is carefully gathered, and sells dear. The rich esteem it a dainty, and, to make it still more delicate, boil it only in steam.

The Rice plant is therefore an undoubted native of India, from which country it has spread over a great part of the world, especially in Asia, where it forms the principal portion of the food of the inhabitants, but it has also from very early times been introduced into the southern parts of Europe. Theophrastus describes it in book iv., c. 5, with other Indian plants, and mentions it as growing in water, and that its inflorescence is like that of milium or panicum, and not in form of a spike. Adam Smith adduces it as one of the most prolific of grains. 'A rice-field produces a much greater quantity of food than the most fertile corn-field. Two crops in the year, from thirty to sixty bushels each, are said to be the ordinary produce of an acre.' Rice is now extensively cultivated in North and South Carolina, and in Georgia; also in Italy and the south of Spain, and likewise a little in Germany. The perfect system of irrigation and tillage which was introduced into Italy at so early a period no doubt rendered the cultivation easy, as the climate is also sufficiently hot and regular.

As the summer temperature of many countries is high, it is easy to cultivate an annual like rice where water is abundant and irrigation easy; but as the summer temperature of most European countries is too low, and not long enough continued, and far from regular, it is hopeless to attempt the culture of a grain which requires so much heat, and which has the disadvantage, from the moisture arising from irrigation, of making a country unhealthy; but this is not the case in the rainy season of tropical countries, where the rice-field is not much more moist than the rest of the country. Its culture has been attempted in England, and a small crop was raised near Windsor, on the banks of the Thames; and it has been hoped that the mountain rice, which is known to grow at considerable elevations in the Himalayan Mountains, might be suited to an English climate. This variety certainly requires a less degree of heat, but it seems to be forgotten that temperature is only one of the elements of climate, and that moisture may be supplied to a plant either by the soil or the atmosphere, and the latter may be moist when the former is comparatively dry. Rice is sown in the Himalayas only in places within the influence of the periodical rains, that is, from about the middle of June to the end of September. In some places it is irrigated, and in others it is not, but rain falls very frequently, and the air is almost always in a moist state, from being charged with moisture from the heated valleys, which is deposited on the mountains, when it reaches an elevation where it becomes cooled beyond the point of saturation. The temperature also is so uniform as not to vary 10° of Fahr. from 70° for three months. So in the Isle of France the mountain rice is cultivated only in the rainy season.

The rice so extensively cultivated throughout India (and the cultivation in China, as described by Sir G. Staunton, is very similar) depends upon rain or irrigation either from rivers or tanks. These Capt. B. Hall (*Frag. of Voyages*, vol. iii., p. 66) describes in one situation, near Nundydroog, as spread over a valley, which was from six to eight miles across, and that they were used for irrigating myriads of rice-fields. The embankments are sometimes miles in length, and then of a waving snake-like shape. One valley was pointed out to Captain Hall, about a mile broad and forty miles long from end to end, which included between thirty and forty tanks, every intermediate square yard of the intermediate spaces being richly cultivated, while the surrounding country appeared to be condemned to perennial sterility.

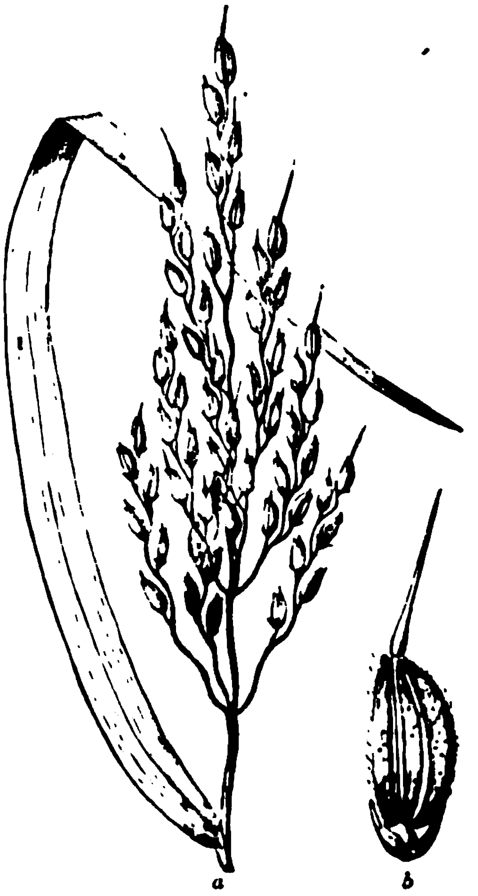
Dr. Roxburgh states that he never saw or heard of an Indian farmer manuring in the smallest degree a rice-field; yet these fields have probably for thousands of years continued to yield annually a large crop of rice, on an average from thirty to sixty fold; even eighty or a hundred has been known. The best rice-fields are extensive open plains through which large rivers pass. The soil is generally of good depth; the best are those annually overflowed by the inundations, from which they necessarily receive some fertilising matter; but the greatest part of the rice lands depend on the rains only, and receive no help except from it and the air. The varieties of rice are innumerable; forty or fifty at least are described. They are divided by Dr. Roxburgh into two kinds; one, called in Telinga, *Poonas*, Sans., *Asoo*, is sown thick in June or July, and transplanted in about forty days, when the plants are about nine to eighteen inches high; the fields are then kept constantly wet; more or less flooded, as some sorts require very little water, while others require a great deal. When the grain is ripe, the water is drained off, and the crop cut down with the sickle: it is either stacked or trod out by cattle. The grain is preserved in pits dug in high ground and lined with the rice straw. The straw is stacked by the careful farmer for feeding his cattle during the hot weather.

The second division of cultivated rice is called *Pedder Worloo* by the Telingas. The grains are awnless, and both the unhusked and husked rice, in most varieties, is white and of excellent quality, though some require much water. In other parts of the country rice is divided, according to the seasons in which it is reaped, into that which ripens in the hot weather of spring, in the summer, or in the winter.

Buchanan states that two crops in the year from the same land do not yield much more than a single good crop would. But the seasons are so uncertain, and the latter crop so liable to fail, that they cultivate as much as possible for the first crop. This is reaped in the rainy season, when the straw cannot be preserved, and as rice-straw is almost the only food which the cattle have in many districts, there is an absolute necessity for sowing the second crop for fodder.

Rice is no doubt the grain which yields food for the largest portion of the human race, but even in India great numbers do not eat rice; in fact in all the north-western provinces wheat is the principal crop, and the natives eat wheaten cakes, and have rather a contempt for rice-eating districts. It abounds however in nourishment, being composed almost entirely of fecula, that is, 96 per cent., and therefore cannot be baked into bread; but it is more easily cooked. It is light and wholesome, and easily digested, and might form a much larger portion of the diet in Europe than it does. Europeans in India eat it at breakfast as well as at other meals, and with fish as frequently as with their curries.

Of the kinds imported into England, the Carolina is the best, and is grown in the marshy grounds of North and South Carolina. The grains are shorter, broader, and boil softer than the Patna rice, which is the best Indian kind known in this country, though in India there are several superior varieties, as for instance the Pilibeet, which are much more esteemed there. In the year 1838, 238,367 cwt. of cleaned and 218,207 cwt. of rough grain were imported into England. The quantity retained for consumption in the United Kingdom, in 1837, was 282,975 cwts.; in 1838, 289,163 cwts., producing a duty in the former year of 25,327*l*., and in 1838, of 24,606*l*. The consumption is in some measure influenced by the price of wheat. The relative values may be judged of by the price of the Carolina rice being 20*s*. when the Patna was 17*s*., Bengal white 13*s*. 6*d*., and the Cargo only 9*s*. 6*d*. The Cargo is a reddish coloured, coarse, but sweetish grain, which is liked by the lower caste of natives of India.



a, panicle of the rice plant, with ripe grains; *b*, a single grain enveloped in its husk and awned.

OSAIBIA, or more properly Ibn* Abi Osaibia, the name commonly given to an eminent Arabic physician, who is called by Nicoll and Pusey (*Catal. Cod. Manuscr. Orient. Biblioth. Bodl.*), Movaffekeddin Abulabbas Ahmed Ben Alcasem Ben Khalifa Ben Junos Ibn Abilcasem Alsaadi Alkhazragi. He was born A.H. 600 (A.D. 1203), and was (as his name implies) of the family of Al-Chazraj, of the tribe of Al-Azd. (Pococke, *Spec. Hist. Arab.*, p. 42, ed. Oxon., 1806.) He informs us himself, in the fourteenth chapter of his work, that he was the pupil of the celebrated Al-Beithar. He studied medicine at Cairo in the lazzaretto founded by Saladin, and was appointed chief physician to the Emir Ezzadin, at Sarchad in Syria, A.H. 635 (A.D. 1238). He died A.H. 668 (A.D. 1269). He is the author of a well-known work entitled 'Oiun al-anba fi thabacat al-athebba' ('Fontes Relationum de Classibus Medicorum'), containing a biographical history of medicine. It is divided into fifteen chapters, of which the first treats of the origin of medicine; the second, of the earliest discoverers in each branch of the profession; the third, of the Greek physicians of the family of Æsculapius (*Asklibious*); the fourth, of the physicians of the school of Hippocrates (Dogmatists); the fifth, of Galen (Galenists) and his contemporaries; the sixth, of the Christian physicians who flourished at Alexandria before the time of Mohammed; the seventh, of Arabian physicians in the time of Mohammed; the eighth, of Syrian physicians under the Abbassides; the ninth, of the translators of the Greek physicians into Arabic; the tenth, of the physicians of Irak and Mesopotamia; the eleventh, of the Persian physicians; the twelfth, of the Indian; the thirteenth, of the Moorish and Spanish; the fourteenth, of the Egyptian; and the fifteenth, of the Syrian. Freind, in his 'History of Physic,' speaks slightingly of this work, but he was acquainted with only a very small portion of it, and was unable to read it in the original language. Reiske, on the contrary (*Opusc. Med. ex Monum. Arab. et Ebraeor.*, 8vo., Halae, 1776), praises it very highly, and gives a tolerably complete analysis of its contents, from which it appears that a great many curious and interesting medical anecdotes and much information relating to the ancient method of practice are to be found in it. It exists at present only in MS. in several libraries of Europe, viz. at Paris, Oxford, and Leyden; but different small portions of it have been published. The life of Bachtishua, translated into Latin by Salomo Negri, is inserted by Freind in his 'History of Physic;' that of Abdallatif was published at Oxford, 1808, 4to., Arab. and Lat., ed. J. Mousley; and a small extract, containing the diploma of a doctor of theology, is to be found in Adler's 'Collect. Nova Nummor. Cuficor.,' 4to., Hafn., 1792, p. 118. There is in the Bodleian at Oxford a MS. Latin translation by Gagnier of the first five chapters. A MS. Latin translation of the whole work by Reiske was left by him at his death, in 1774, to Bernard (probably the same physician who edited several Greek medical treatises); this has never been published, and what has become of it since Bernard's death, in 1793, the writer has not been able to discover. (See Nicoll and Pusey, *loco cit.*; De Rossi, *Dizion. Stor. degli Autori Arabi*; and Reiske, *loco cit.*)

---

* As few Arabic names have been more corrupted, it may be useful to mention that it is sometimes spelled Abu, Abou, or Abi [illegible], [illegible], [illegible], [illegible], Osaibia, Osbeia, Osaibe, Osbaia, Osaibea, &c.

OSACCA. [JAPAN.]

OSCI, or O'PICI, a people of antient Italy, who seem to have been identical with the Ausonians, or Aurunci, and who inhabited the southern part of the peninsula. Some critical writers consider the Ausonians to be a branch of the Osci; others, as Polybius, have spoken of them as distinct tribes, but this appears to be an error. The names Opicus and Oscus are undoubtedly the same. Aristotle (*Polit.*, vii. 10) calls the country from the Tiber to the Silarus, Ausonia and Opica; and other antient writers extended the name much farther, to the Straits of Sicily, but the southern extremity of the peninsula appears to have been occupied previously by the Œnotrians, a Pelasgic people, who were conquered by the Lucanians and Bruttii. Cumae, one of the earliest Greek colonies on the coast of Italy, was in the country of the Opici. The early immigrations of the Illyrians or Liburnians along the eastern coast of Italy drove the aboriginal inhabitants from the lowlands into the fastnesses of the central Apennines, from whence they issued under the various names of Umbri, Sabini, and Osci, or Latini Veteres. There was an antient tradition as late as the time of the historian Dionysius, of a sudden irruption of strangers from the opposite coast of the Adriatic, which caused a general commotion and dispersion among the aboriginal tribes. Afterwards came the Hellenic colonies, which occupied the whole sea-coast from Mount Garganus to the extremity of the peninsula, in the first and second centuries of Rome, in consequence of which the population of the southern part of the Italian peninsula became divided into two races, the tribes of aboriginal or Oscan descent, such as the Sabini, Samnites, Lucanians, and Bruttii, who remained in possession of the highlands, and the Greek colonists and their descendants, who occupied the maritime districts, but never gained possession of the upper or Apennine regions. Such is the view taken by Micali and other Italian writers; but Niebuhr (*History of Rome*, vol. i.) describes the Sabini, and their colonies the Samnites, Lucanians, and other tribes which the Roman writers called by the general name of Sabellians, as a people distinct from the Osci or Opici. He says, after Cato and other antient historians, that the Sabini issued out of the highlands of the central Apennines near Amiternum, long before the epoch of the Trojan war, and driving before them the Casci or Prisci Latini, who were an Oscan tribe, settled themselves in the country which has to this day retained the name of Sabina. From thence they sent out numerous colonies, one of which penetrated into the land of the Opicans, and became the Samnite people; and afterwards the Samnites occupied Campania, and, mixing themselves with the earlier Oscan population settled there, and adopted their language. But farther on, speaking of the Sabini and Sabellians, Niebuhr admits the probability of their being originally a branch of the same stock as the Opici or Osci. Micali considers the Sabini, Apulians, Messapians, Campanians, Aurunci, and Volsci, as all branches of the great Oscan family.

The Greeks, being superior to the native tribes in refinement and mental cultivation, affected to despise them, and they applied to the native Italian tribes, including the Romans, the adjunct Opicus, as a word of contumely to denote barbarism both in language and manners (Cato apud Plin., xxix. 1); and the later Roman writers themselves adopted the expression in the same sense: 'Osce loqui' was tantamount to a barbarous mode of speaking. Juvenal (iii. 207) says,

'Et divini Opici rodebant carmina mures;'

and Ausonius uses 'Opicas chartas' to mean rude unpolished compositions. The Oscan language was the parent of the dialects of the native tribes from the Tiber to the extremity of the peninsula, Sabini, Hernici, Marsi, Samnites, Sidicini, Lucanians, and Bruttii, whilst in the regions north of the Tiber the Etruscan predominated. Livy (x. 20) mentions the Oscan as being the language of the Samnites. The older Latin writers, and especially Ennius, have many Oscan words and Oscan terminations. The Oscan language continued to be understood at Rome down to a late period under the empire. [ATELLANAE FABULAE.] In the Social War, the Confederates, who were chiefly people of Oscan descent, stamped Oscan legends on their coins. In Campania and Samnium the Oscan continued to be the vulgar tongue long after the Roman conquest, as appears from several monuments, and especially from the Oscan inscriptions found at Pompeii. (Micali, *Storia degli Antichi Popoli Italiani*, ch. xxix., and *Atlas*, pl. 120; and De Jorio, in his *Plan of Pompeii*, Naples, 1829, pl. 4.)

The Oscan race, like the Etruscan, appears to have been from the remotest times strongly under the influence of religious rites and laws (Festus, under the head 'Oscum'), and the primitive manners and simple morals of the Oscan and Sabine tribes, as well as their bravery in arms, have been extolled by the Roman writers, among others, by Virgil (*Æneid*, vii. 725-730), and Silius Italicus (viii. 525-529).

Concerning the scanty remains of the Oscan language which have come down to us, see 'Linguae Oscae Specimen singulare quod superest Nolae in marmore Musaei Seminarii,' which is given by Passeri, in his 'Picturae Etruscorum in Vasculis,' &c., Rome, 3 vols. fol., 1767-75; and also Guarini, 'In Osca Epigrammata nonnulla Commentarium,' Naples, 8vo., 1830, where several Oscan inscriptions are found collected. For Niebuhr's views on the Opici or Osci, see his 'Roman History,' vol. i.

OSCILLATION and CENTRE OF OSCILLATION. When any system is slightly disturbed from its position of equilibrium, it either falls altogether or endeavours to recover the position which it lost. In the latter case the equilibrium is said to be stable, and in the former unstable. A pendulum hanging downwards is an instance of the stable kind, and the same pendulum, if it could be so nicely adjusted as to rest immediately over the pivot, would be of the unstable kind. But unstable equilibrium is a practical impossibility, since any degree of departure from the proper position would destroy the equilibrium; and those cases in which an apparently unstable position of equilibrium is actually gained, as in a bar resting on two inclined planes, owe the continuance of the equilibrium to the effect of friction. [STABLE AND UNSTABLE.]

When a system endeavours to recover its position, it acquires some velocity in the process; so that, though it would rest at the position of equilibrium if that velocity were then destroyed, it is really urged through the position by the velocity acquired, and continues to depart from it on the other side until, by the forces which act to restore it to the position, all the velocity acquired has been destroyed. Repetitions of the same phenomenon then take place in succession, the body never remaining still when it has attained the position of equilibrium, since it never is in that position except when moving with the velocity acquired in its descent to the position. If then there were neither friction nor resistance of the air to help in destroying this velocity, it would be a universal law of mechanics that a system disturbed from its position of equilibrium would never recover it, but would make perpetual oscillations about it.

In the widest sense, the problem of oscillations includes most of those which occur in astronomy, optics, &c. The moon and planets add to their average motions small oscillations about their mean places: the tides consist of oscillations of the ocean about the uniform spheroid, which, but for the action of the heavenly bodies, would be carried round in the diurnal rotation of the earth; the phenomena of light are produced by the oscillations which take place in an elastic æther; those of sound, by the oscillations of the air; and so on. Usually however the problem of oscillation refers to nothing more than the oscillations of a solid system, acted on by gravity, about a horizontal axis, the original departure from the position of equilibrium being but small; in fact, to the purely theoretical part of the problem of the Pendulum, to which we shall here confine ourselves, giving the investigations in a brief form, since it is impossible, within our limits, to explain the numerous points alluded to with sufficient illustration for a learner.

Let a material point, a very small body, be attached by a string or rod without weight to an immoveable pivot. In the position of rest the string hangs vertically: let us now suppose it removed out of the vertical position, and let go when it makes an angle α with the vertical. When t seconds have elapsed, let it make an angle θ with the vertical. The material point is acted on by gravity with a force which would produce an acceleration g (or 32·1908) feet in one second: if then l be the length of the string, the arc $l\theta$, through which the point must move before it arrives at the lowest point of its course, is diminished with a velocity which is accelerated by $g \sin\theta$ at the time specified, giving, by the well-known equations of motion,

$$\frac{d^2 . l\theta}{dt^2} = -g \sin\theta, \text{ or } l\frac{d^2\theta}{dt^2} + g\sin\theta = 0.$$

The first integration of this gives

$$l\left(\frac{d\theta}{dt}\right)^2 = 2g\,(\cos\theta - \cos\alpha),$$

since it is a condition that the motion began when θ was $=\alpha$. This gives

$$dt = -\sqrt{\frac{l}{g}} \cdot \frac{d\theta'}{\sqrt{(\sin^2\alpha' - \sin^2\theta')}}$$

α' and θ' being the halves of α and θ, and the negative sign being taken because θ' diminishes as t increases. The integration of this is facilitated by assuming $\sin\theta' = \sin\alpha' . \sin\phi$, which gives

$$\sqrt{(\sin^2\alpha' - \sin^2\theta')} = \sin\alpha' \cos\phi,$$

$$d\theta' = \frac{\sin\alpha' \cos\phi . d\phi}{\sqrt{(1 - \sin^2\alpha' . \sin^2\phi)}}$$

$$dt = -\sqrt{\frac{l}{g}} \cdot \frac{d\phi}{\sqrt{(1 - \sin^2\alpha' . \sin^2\phi)}}$$

$$= -\sqrt{\frac{l}{g}} \cdot \left\{1 + \frac{1}{2}P^2 + \frac{1.3}{2.4}P^4 + \frac{1.3.5}{2.4.6}P^6 + \ldots\right\} d\phi$$

where P stands for $\sin\alpha' . \sin\phi$. To find the time of a semi-vibration, this must be integrated from $\theta' = \alpha'$ to $\theta' = 0$, or from $\phi = \frac{1}{2}\pi$ to $\phi = 0$, that is, after change of sign, from $\phi = 0$ to $\phi = \frac{1}{2}\pi$. Now between these limits

$$\int \sin^{2n}\phi . d\phi = \frac{1.3.5 \ldots . 2n-1}{2.4.6 \ldots . 2n} \cdot \frac{\pi}{2}$$

whence, changing the sign of the preceding and integrating each term by this formula, we find the time of a semi-vibration. Double this, to find the time of a vibration, which call T, and we have

$$T = \pi\sqrt{\frac{l}{g}} \cdot \left\{1 + \frac{1}{4}\sin^2\alpha' + \frac{1.9}{4.16}\sin^4\alpha + \frac{1.9.25}{4.16.36} \cdot \sin^6\alpha' + \ldots\right\}$$

very convergent series. If α' be small, we have, with an ror of the second order only,

$$T = \pi\sqrt{\frac{l}{g}};$$

or the time of vibration of the same pendulum in different small arcs is very nearly independent of the lengths of the arcs; a result which might be obtained from the considerations given in the article Isochronism, for the acceleration $g \sin\theta$, θ being small, is very nearly $g\theta$, that is, very nearly as the arc measured from the lowest point. To take in two terms of the series is very nearly equivalent to multiplying the preceding value of T by $1 + \frac{1}{16}\alpha^2$.

The number of vibrations in a mean solar day of the pendulum whose length is l, placed in a vacuum, is

$$\frac{86400\sqrt{g}}{\pi\sqrt{l}}\left\{1 - \frac{1}{16}\alpha^2\right\} \text{ very nearly.}$$

Next, let a number of material points invariably connected together vibrate about a horizontal axis. It is required to find at what distance a single material point must be hung that it may vibrate in the same manner.

Let there be a number of material points, or infinitely small bodies, having the masses m, m', m'', &c., invariably connected with each other, and with an horizontal axis of rotation, their perpendicular distances from the axis being l, l', l'', &c. Let $M = m + m' +$, &c., be the sum of all the masses, and let k be the perpendicular distance of the centre of gravity of the whole from the axis. When the last-mentioned perpendicular distance makes an angle θ with the vertical, the moving force is Mg acting in the direction of gravity at the distance $k \sin\theta$, and acting with a moment of rotation $Mgk \sin\theta$. Let ϕ be the angular velocity at the time in question, which becomes $\phi + d\phi$ at the end of a new interval dt; then taking the mass m for consideration, we have $l\phi$ for its actual velocity, and $l\,d\phi$ for the increment in the time dt, whence $m\,l\,d\phi$ is the actual momentum gained, $m\,l\frac{d\phi}{dt}$ the moving force which would produce that momentum. This force acting at the distance l, and perpendicularly to that distance, would exert a moment of rotation $m\,l^2\frac{d\phi}{dt}$. Ascertain in the same way the moments of rotation of the other masses; then by the equivalence of the impressed and effective forces [Virtual Velocities] we must have—

$$m\,l^2\frac{d\phi}{dt} + m'l'^2\frac{d\phi}{dt} + \ldots \qquad = Mgk\sin\theta.$$

But ϕ is $-\frac{d\theta}{dt}$, thus written since $\frac{d\theta}{dt}$ is negative; if then we denote $m\,l^2 + m'l'^2 + \ldots$ (which is the Moment of Inertia) by $\Sigma m\,l^2$, we readily deduce from the preceding

$$\frac{d^2\theta}{dt^2} + \frac{Mk}{\Sigma m\,l^2} \cdot g\sin\theta = 0.$$

The question of the motion of this system is now completely reduced to that of a simple pendulum; for if we compare the preceding equation with that of the motion of a simple pendulum, we find that the two would agree if the length (there called l) of the simple pendulum were $\Sigma m\,l^2 : Mk$, or;—any rigid system which makes oscillations about an horizontal axis, oscillates in the same manner as a simple pendulum, the length of which is the moment of inertia of the system with respect to its axis divided by the product of the whole mass and the distance of the centre of gravity from the axis. If in the line k or its continuation, a distance equal to $\Sigma m\,l^2 : Mk$ be set off from the axis, the moving extremity is called the centre of oscillation, as being that point in which the whole mass might be collected without any alteration of the law of oscillation.

Let G be the moment of inertia when the axis passes through the centre of gravity and is parallel to the given axis; then [Moment of Inertia] $\Sigma m\,l^2 = G + Mk^2$, whence the distance of the centre of oscillation from the axis is $(G + Mk^2) : Mk$ or $(G : Mk) + k$. Hence the centre of oscillation is always farther from the axis than the centre of gravity by $G : Mk$. Let this be called h: we have then

$$hk = \frac{G}{M}.$$

Now G and M are independent of the position of the axis, G depending only on the masses and manner in which the masses are distributed about the centre of gravity, and M on the amount of the masses. If then a new axis of suspension were taken, distant by h from the centre of gravity on the other side, that is, if a new axis of suspension were taken passing through the first centre of oscilla-

[illegible] and if h' were the distance of the new centre of oscillation from the centre of gravity, we should have

$$h'k = \frac{G}{M}, \text{ but } hk = \frac{G}{M}, \text{ whence } h' = h;$$

that is, the old axis of suspension contains the new centre of oscillation, if the new axis of suspension contains the old centre of oscillation. This is generally expressed thus: the centres of suspension and oscillation are reciprocal. When the body is a continuous mass, the preceding investigations apply, but the integral calculus must be employed to determine G.

OSCULATION, a term used instead of contact by foreign writers. [CONTACT; TANGENT.]

OSCULUM PACIS. [PAX.]

OSIER is the name given to various species of Salix, or willow, employed in basket-making on account of their tough flexible shoots. The following table of the best species, showing the length to which their annual shoots will grow under favourable circumstances, and the purposes to which they are most suitable, is chiefly compiled from Loudon's 'Arboretum Britannicum,' page 1470, to which the reader is referred for full information upon such points.

Names.	Length of annual Shoots.	Use.
Salix purpurea.	3 to 5 feet.	For finer basket-work much esteemed.
Salix Forbyana.	5 to 7 feet.	For finer wicker-work, basket-making, &c.
Salix rubra.	5 to 9 feet.	One of the most valuable for bands, crates, &c.
Salix lanceolata.	5 to 8 feet.	For hampers, crates, and coarser work.
Salix triandra (or French willow).	8 to 9 feet.	Its long tough pliant shoots render it one of the most valuable for white basket-work.
Salix decipiens.	6 to 8 feet.	Often cultivated, but soon wears out, and is of little value.
Salix vitellina (golden osier).	5 to 7 feet.	Very tough, but the rods have too much spray. Much cultivated in osier-grounds.
Salix viminalis (osier withy, and velvet osier).	10 to 12 feet.	Highly esteemed for basket-making and hoops.

The distinctions of these species are mentioned under SALIX.

OSI'RIS, one of the principal Egyptian deities, was the brother of Isis and the father of Orus [ISIS; ORUS], and is said by many writers to have been the first king of Egypt. His history is given in the first book of Diodorus, and in the treatise of Plutarch, 'On Isis and Osiris;' but it is not improbable that the genuine Egyptian traditions respecting this deity had been considerably corrupted at the time of these writers. According to their accounts however, Osiris was the first who reclaimed the Egyptians from a state of barbarism, and taught them agriculture and the various arts and sciences. After he had introduced civilization among his own subjects, he resolved to visit the other nations of the world, and confer on them the same blessing. He accordingly committed the administration of his kingdom to Isis, and gave her Hermes to assist her in council and Hercules to command her troops. Having collected a large army himself, he visited in succession Ethiopia, Arabia, and India, and thence marched through central Asia into Europe, instructing the nations in agriculture and the arts and sciences. He left his son Macedon in Thrace and Macedonia, and committed the cultivation of the land of Attica to Triptolemus. After visiting all parts of the inhabited world, he returned to Egypt, where he was murdered soon after his arrival by his brother Typhon, who cut up his body into twenty-six parts, and divided it among the conspirators who assisted him in the murder of his brother. These parts were soon afterwards, with one exception, discovered by Isis, who enclosed each of them in a statue of wax, made to resemble Osiris, and distributed them through different parts of Egypt. This story appears to allude to the fact mentioned by Herodotus, that Osiris was the origin of the mummy form.*

Both antient and modern writers have differed considerably respecting the peculiar attributes and powers of this deity. Many of the antients believed that he represented the sun or the Nile; while his discovery of the vine and his expedition to India led others to identify him with Dionysus. (Herod., ii. 144.) Herodotus informs us (ii. 42) that the festival of Osiris was celebrated in almost the same manner as that of Dionysus. It appears however not improbable that the worship of Osiris was introduced into Egypt, in common with the arts and sciences, from the Ethiopian Meroe. We learn from Herodotus (ii. 29) that Zeus (Ammon) and Dionysus (Osiris) were the national deities of Meroe; and we are told by Diodorus (iii. 3) that Osiris led a colony from Ethiopia into Egypt.

Osiris was venerated under the form of the sacred bulls Apis and Mnevis (Diod., i. 21); and as it is usual in the Egyptian symbolical language to represent their deities with human forms and with the heads of the animals which were their representatives, we find statues of Osiris represented with the horns of a bull. (*Egyptian Antiquities*, vol. ii., p. 295, 12mo., 1836.)

Osiris, in common with Isis, presided over the world below; and it is not uncommon to find him represented on rolls of papyrus as sitting in judgment on departed spirits. His usual attributes are the high cap, the flail or whip, and the crosier. He is also frequently represented with an artificial beard.

OSMAZOME, a name given by Thénard, and adopted by most chemists, to a spirituous extract of meat; according however to Berzelius it is not a peculiar substance but a mixture of several different bodies, among which are lactic acid and lactates. In the opinion of Berzelius the name ought to be abandoned. According to the experiments of Chevreul however osmazome contains a peculiar substance, to which he has given the name of *creatine* (from κρέας, flesh).

Creatin is solid, inodorous, insipid, colourless, and has a pearly lustre; it does not act upon test papers, and crystallizes in right prisms. Its specific gravity varies from 1·35 to 1·34. When heated it crackles, loses water at 212°, and melts without being discoloured; but on continuing the heat it decomposes, yielding ammonia. At 55° Fahr., 100 parts of water dissolve about 1·2 part; this solution is scarcely at all acted upon by saline or metallic substances. The solution slowly decomposes, exhaling a distinct ammoniacal odour and becoming turbid. Alcohol and most acids also dissolve it.

OSMIUM. This metal was discovered by Mr Smithson Tennant, in the year 1803, in the grains of native platinum [PLATINUM], along with another metal [IRIDIUM]. This compound, called *osmiuret of iridium*, occurs in flat grains and hexagonal crystals. The primary form is a rhomboid. Cleaves perpendicular to the axis. Hardness 4·5 to 5·1, exceeding that of native platinum. Colour iron-grey and pale steel-grey. Lustre metallic. Opaque. Specific gravity 19·5. Insoluble even in aqua regia; becomes black when fused with nitre, and when heated in a tube exhales a peculiar odour.

Berzelius analysed three varieties of osmiuret of iridium, from Siberia, with the annexed results:—

Osmium . .	80	74·9	49·34
Iridium . .	20	25·1	46·77
Rhodium . .	.	.	3·15
Iron . .	.	.	0·74
Palladium . .	.	.	trace.
	100	100·	100·

The separation of osmium from iridium is effected by a tedious process. This metal has the following properties:—it is white, with a bluish grey tint. It may be reduced to leaves. Its specific gravity is 10. It is unalterable in the air at common temperatures, but if strongly heated is oxidized. When it has been exposed to a very high temperature, acids do not dissolve it; but under common circumstances it dissolves completely, though slowly, in nitric acid, and more readily in aqua regia. In both these cases osmic acid is formed.

Protoxide of Osmium.—When potash is added to a solution of chloride of osmium, the protoxide is precipitated in the state of hydrate, and is of so dark a green colour as to appear nearly black. This hydrate dissolves slowly in acids, forming dark green coloured solutions; these do not yield crystals by evaporation, but leave green or greenish-brown translucent residues. When the hydrate is heated rather below redness, it loses water. It detonates when heated with certain combustible bodies.

---

* Herodotus says (ii. 86), 'The most [illegible]' [illegible]

It is composed of 1 equivalent of oxygen 8 + 1 equivalent of osmium 100=108.

Sesquioxide of Osmium has not been procured in a separate state, but is obtained in combination with ammonia when the binoxide is heated with excess of this alkali; azote is evolved during the operation by the decomposition of a portion of the binoxide and of the ammonia.

Binoxide of Osmium is formed and precipitated by pouring a solution of carbonate of soda into a saturated solution of bichloride of osmium and potassium. The precipitation takes place gradually, and after separating, by means of hydrochloric acid, a little soda which it retains, it is obtained in a state of purity; it is of a black colour and insoluble in acids. It consists of 2 equivalents of oxygen 16+1 equivalent of osmium 100=116.

Teroxide of Osmium is prepared from the terchloride in the same way as the binoxide from the bichloride. Its existence however is not perfectly established, but is admitted by Berzelius from analogy. If it exist, it of course consists of 3 equivalents of oxygen 24 + 1 equivalent of osmium 100=124.

Peroxide of Osmium, or *Osmic Acid*.—This is a very curious compound, differing remarkably from all the preceding substances. It is obtained whenever osmium is burnt in the air or in oxygen gas, or when the metal is heated with hot nitric acid. It is white, very volatile, extremely fusible, soluble in water, and crystallizable. It possesses an extremely disagreeable odour, somewhat resembling that of chlorine. This property suggested the name of the metal (ὀσμῆ, *odor*). It has no acid reaction, except that of combining with alkalis, forming compounds which are called osmiates. When sulphurous acid is added to a solution of osmic acid, it is rendered yellow, orange, brown, green, and blue, dependent upon the extent to which the deoxidizement is carried on. It stains the skin, is acid and poisonous. It is composed of 4 equivalents of oxygen 32+1 equivalent of osmium 100=132.

Chlorine and osmium, according to Berzelius, combine in four different proportions, and sulphur and osmium also unite to form several sulphurets. This very peculiar metal also forms alloys with some others, but these compounds are not of sufficient importance to require a description.

OSNABRÜCK (generally written *Osnaburg* in English) is a province of the kingdom of Hanover. It is divided into the following parts:—The principality of Osnabrück, 903½ square miles; the lower county of Lingen, 126½ square miles; the circles of Meppen and Emsbuhren, 693 square miles; and the county of Bentheim, 399 square miles: the area of the whole is 2122 square miles, and the population 227,000. The whole country is a part of the plain of northern Germany, but is traversed in the south by two chains of hills; within and to the south of these hills there is good arable land, but as soon as you leave their vicinity everything is changed. Immense heaths, moors, morasses, and sandy deserts alternate with vast levels; except near the rivers, the soil is poor and the vegetation scanty. This province contains the Hümling, an extensive uninterrupted sandy desert, which is 25 miles in circumference, where the wind raises columns of sand as in the deserts of Africa, and which is entirely surrounded by vast and impenetrable morasses: it is beyond comparison the most dismal tract in all Germany. The largest river is the Ems, which waters only the western part, and becomes navigable after being joined by the Hase, the second principal river; all the other streams are mere rivulets or brooks. In the south there are many good springs; in the north they are fewer and have more or less a marshy taste. The climate is temperate, but the horizon is generally overcast and cloudy. Fetid exhalations often arise from the marshes, but do not seem to be injurious to health, for human life is as long here as elsewhere, and the cattle are remarkable for their size and beauty. Agriculture is not in a flourishing state, and the country does not produce sufficient corn for its own consumption. Hemp and flax are grown in considerable quantities. There is only one principal manufacture, that of linens, which is carried on to a very great extent, especially in the principality of Osnabrück and in Lingen. Though considered as an occasional occupation, it is often more profitable than agriculture. The value of the coarse linens (called Osnaburgs) annually exported is 200,000 dollars. The thread is all spun in the country. In the circle of Meppen, which is the poorest part of the country, and is unable to support the scanty population, who are a very industrious and temperate people, vast quantities of woollen stockings are knit and exported to Holland. They also derive some profit from the breeding of horned cattle, sheep, and bees. They export also a good deal of turf and peat. The greater part of the men of Meppen (5000 or 6000 perhaps) go in summer to find work in Holland, from which they annually bring back 18,000 or 20,000 pounds sterling. There are some woollen, leather, and snuff and tobacco manufactories in the large towns, and shipbuilding is carried on at Papenburg, where above sixty ships are annually built.

Osnabrück was formerly a bishopric and of very great antiquity, being the first that was founded in Saxony by Charlemagne. The first bishop was Wido, a Frieslander. After the Reformation the inhabitants embraced the Lutheran faith, and it was decided by the treaty of Westphalia that it should be governed alternately by a Roman Catholic and a Protestant bishop, the latter to be always a prince of the house of Brunswick-Lüneburg. As the Catholic bishop was generally an old canon and the Protestants always chose a young prince, the country remained for a long time under the electoral house of Brunswick: the last bishop of that house was the late Duke of York. In the year 1802 the country was made over to Hanover as an hereditary temporal principality, in consideration of certain territorial cessions. It was afterwards annexed first to the kingdom of Westphalia and then to the French empire, and was recovered by its antient sovereign on the fall of Napoleon.

Osnabrück, the capital, is situated in 52° 16′ N. lat. and 8° 1′ E. long., in a valley on the river Hase. It is surrounded with a wall and ditch, and has five gates. Like most of the old German towns, it is irregularly built. It is the seat of the provincial government and chancery, the residence of a Roman Catholic vicar-general and chapter, and of a Lutheran consistory. The most remarkable public buildings are, the palace, built in 1665, the cathedral, the Roman Catholic church of St. John, the Lutheran churches of St. Mary and St. Catherine, and the fine town-hall, in which the treaty of Westphalia was concluded at the same time as at Münster. There are a Catholic and a Lutheran gymnasium, a Lutheran and 2 Roman Catholic orphan-houses, a seminary for schoolmasters, 3 hospitals, several elementary schools, and a Bible Society. The inhabitants, amounting to 11,000, have manufactures of coarse woollens, leather, linen, and tobacco. The linen manufactured in the adjacent country is brought here to be measured and stamped. There are several bleaching-grounds, a paper-mill, a chicory coffee manufactory, &c.

(Hassel; Stein; Stüve, *Beschr. des Fürstenthums Osnabrück*; J. Möser, *Osnabr. Geschichte*; Reinhold, *Das Bisthum Osnabrück*.)

OSPREY. [Bald Buzzard.]

OSROE'NE. [Mesopotamia.]

OSSA, MOUNT. [Thessaly.]

OSSOLA. [Novara, Valli di.]

OSSEOUS BRECCIA. A considerable number of the bones of mammalia discovered by geological researches have been found in clefts of limestone rocks, wholly or partially filled by a mingled mass of calcareous fragments and portions of bones, more or less perfectly cemented by carbonate of lime often in a crystallized state. This bony breccia abounds in the clefts of the limestone rocks of Gibraltar, Nice, and other parts of the Mediterranean shores; and in Cuvier's magnificent work 'Ossemens Fossiles' a large number of interesting quadrupeds and some birds are stated to have been obtained from them.

OSSIAN'S POEMS. In the article Macpherson the circumstances connected with the publication of these poems, and of others which preceded them, are briefly mentioned. Macpherson affirmed that they were translations made by himself from antient Erse manuscripts, which he had collected in the Highlands of Scotland, and which were the genuine compositions of Ossian, a Highland poet, who lived about the middle of the third century, and whose poetical works had been transmitted orally from bard to bard and from age to age, till the introduction of the art of writing into the Highlands afforded the means of fixing them in those manuscripts from which the translations were made.

The truth of this statement was denied by Dr. Johnson, who boldly pronounced the whole of the poems ascribed to Ossian to be forgeries, and defied Macpherson to produce a manuscript of any Erse poem of earlier date than the sixteenth century. Hume, Gibbon, and others, though they did not express so decided an opinion, seemed to more than doubt their authenticity. On the other side, Dr. Blair defended them in an elaborate 'Critical Dissertation;' Dr. Henry, in his 'History of Great Britain,' founded many of his statements relating to the early condition and manners of the inhabitants of the northern part of the island exclusively upon their authority; Lord Kames, in his 'Sketches of Man,' appealed to them as substantiating his theories; Cesarotti prefixed to his Italian translation, which improved their beauties and softened their defects, a dissertation in which he speaks of Ossian as equal if not superior to Homer; Arthur Young lent his aid on the same side; and the whole body of the Highlanders seemed ready to do battle in the cause of the Gaelic bard.

In the year 1800, Malcolm Laing added to the 2nd volume of the first edition of his 'History of Scotland' a dissertation in which he endeavoured to establish, from historical and internal evidence, that the 'Poems of Ossian' were, without a single exception, entirely spurious.

The Highland Society at Edinburgh, in 1797, appointed a Committee to inquire into the authenticity of the 'Poems of Ossian.' A list of queries was sent to every person who was likely to afford information on the subject, antient Erse and Irish manuscripts were assiduously sought after, and all the traditions existing in the Highlands which had any relation to the subjects of the poems were carefully collected. In 1805, when the Committee had completed their labours, they published their Report, with the name of Henry Mackenzie annexed to it as their chairman. The Report states, that 'the Committee had not been able to obtain any one poem the same in title and tenor with the Poems of Ossian.' About the same time was published a splendid edition of 'The Poems of Ossian, &c., containing the Poetical Works of James Macpherson, Esq., in Prose and Rhyme; with Notes and Illustrations by Malcolm Laing.' The object of these notes and illustrations was to destroy the authority and depreciate the value of the text.

The research, the acuteness, and the close reasoning of Laing both in his dissertation and in the notes to his edition of the poems, together with the admissions made in the Report of the Highland Society, appeared to have nearly decided the question against Macpherson. The controversy however, as far at least as relates to the historical authority of the poems, can hardly be said to be terminated. In 'The Highlanders of Scotland, their Origin, History, and Antiquities,' by W. Skene, a work published in 1837 at the request of the Highland Society of London, we are informed, that 'by a fate altogether singular in the case of the Highlanders, a complete body of those antient versified histories have been handed down in the Poems of Ossian' (vol. i., p. [illegible]); and that 'the value of Ossian as an historical poet, must stand in the highest rank, while, whether the first part of these poems are of antient or of modern composition, there can remain little doubt that in him we possess the oldest record of the history of a very remote age' (vol. i., p. 212).

Having thus given a short detail of the nature, progress, and present state of the controversy relating to these poems, we shall now offer, as briefly as we can, first, what appear to us to be the most important facts and arguments which bear upon their authenticity; and, secondly, our own estimate of their poetical value.

Of the languages spoken by the Gaelic nations who inhabited the western parts of Europe in the time of Julius Cæsar, the Irish is probably that which has suffered least by mixture with others. The Erse, spoken in the Highlands of Scotland, approximates so closely to the Irish, that it may be considered rather as a dialect of it than a distinct language. But while the Irish has been a written language from an era probably anterior to the Christian, with an antient alphabet, and a series, not only of bards, but of historical annalists, of whose works there are manuscripts still extant of as early a date as the eleventh century, there is no evidence that the Erse was ever written previous to the fifteenth or sixteenth century. If then these poems were composed by Ossian, in Erse, at the end of the fourth century, they must have been preserved by tradition for thirteen or fourteen hundred years. The Irish, with all the advantage of writing to fix it, has suffered so much alteration, that the oldest manuscripts are understood with difficulty even by those who are most learned in the language, and some are quite unintelligible. We have therefore a right to infer that the Erse, unwritten, and spoken by a people at least as rude as the Irish, has undergone a similar change; and that these poems, if preserved in the words in which they were composed by their supposed author, could not be understood by the present race of Highlanders.

Macpherson published the Erse of the seventh book of 'Temora,' but it was printed from a copy in his own handwriting, and the original has never been produced. Macpherson of Strathmashie, a poet who assisted, as he affirms, in transcribing the poems from old manuscripts or from oral tradition, said that one of these old manuscripts was dated in 1410; and Lord Kames, in his 'Sketches of Man,' asserts, that the four first books of 'Fingal' were obtained from a Gaelic manuscript, written on vellum in 1403, and found by the translator in the Isle of Skye. No doubt Macpherson told him so, but he does not say that he saw the manuscript, nor has it ever been produced. Indeed the oldest Scotch MS. extant, a copy of Winton's Chronicle, in the Royal Library, Edinburgh, is not of an earlier date than 1420. As to the Erse manuscripts, frequent appeals were made by Macpherson's friends to the 'Red Book' of the bard of the Clanronald family, which was in Macpherson's possession, and was said to contain 'some of the poems which are now translated and published.' It was obtained from him, but not till he was actually threatened with a prosecution by the Clanronald family, and was found to be a small 12mo. of one hundred and fifty leaves, written in the Irish character, and dated September 8, 1720, in the midst of the songs. It was found to contain only one poem which had any relation to Ossian, a short ballad on the longevity of the Fions. Another appeal was made to 'a large folio MS.' called the 'Red Rhymer,' which was stated to have been given 'by Mr. Macdonald of Glenalladale in Muidart, to Mr. Macdonald of Kyles in Cnoideart, who gave it to Mr. Macpherson. It contains a variety of subjects, such as some of Ossian's poems, Highland tales, &c.' Laing applied to Mr. Mackenzie, the gentleman to whom Macpherson bequeathed his MSS. and the publication of his Erse 'Ossian' (mentioned below), for the production of this MS. We give the result of this application in Laing's own words: 'In consequence of this requisition, sixteen manuscript volumes, in quarto and octavo, were transmitted to Edinburgh; but the "Red Rhymer" in folio, the only remaining MS. ever specified or appealed to for the originals of Ossian, was not produced. The MSS. consisted of medical and religious treatises, Irish legends and legendary histories, an obituary, a vocabulary, genealogies, &c., with many of the Irish ballads ascribed to Ossian, but not a single original, as far as could be discovered, of Macpherson's pretended translation of Ossian.'

A subscription of 1000*l.* was raised by Macpherson's countrymen in the East Indies to defray the expense of publishing the supposed Erse originals. It was placed in Macpherson's hands, and he retained it till his death, when he left it to be applied to the purpose for which it was raised. In 1807 appeared 'The Poems of Ossian, in the original Gaelic, &c.; with Notes and Observations, by John M'Arthur.' London, 3 vols. 8vo. This edition was accompanied by a literal Latin translation, by Robert Macpherson, and preceded by a dissertation on the authenticity of the poems by Sir John Sinclair. Still there were no antient manuscripts; the 'original Gaelic' was printed entirely from Macpherson's hand-writing, and corresponded literally with the English, which, there is no doubt, was translated into Gaelic by Macpherson himself. He had abundance of time for this task before he died, and is known to have been well qualified for it, Erse, not English, being his native language.

The truth is, that not a manuscript, nor a fragment of a manuscript, of any antient poem, Erse or Irish, which Macpherson has translated in his 'Ossian,' has ever been discovered. Ballads indeed there are, some in Erse, but many more in Irish, in which the Ossianic heroes are celebrated; there is a large manuscript collection of them in the Dublin University Library, several of which were published by Miss Brooke in 1789 with an English poetical version; and there are traditions, not only in Ireland, but also in Scotland, especially in Argyleshire and other districts of the West Highlands, relating to Fingal, Ossian, &c. Some of these ballads and traditions have supplied circumstances, or names, or incidental allusions, which have been worked up into the Ossianic collection; so that the Highland reader was continually reminded of something which was familiar to his imagination, and having found parts which he thought he knew, was ready to claim the whole. These materials have been carefully compared, both by Laing and the Highland Society, with the poems, and the use which has been made of them in each instance specifically pointed out.

According to 'Ossian's Poems,' Fingal was king of Morven, which may be supposed to represent Argyleshire and the adjoining parts of the West Highlands; here he had his palace of Selma (a name never heard of before the publication of 'Ossian's Poems'), and here his father Comhal, his grandfather Trathal, and his great-grandfather Trenmor reigned. Ossian was the son of Fingal, and Oscar the son of Ossian. For this kingdom and its kings there is absolutely no foundation in the annals of the Highlands or of the Highland clans; in some Erse ballads however and Highland traditions Fingal and Ossian are occasionally spoken of as Highland heroes, but in others they are mentioned as Irish. On the contrary, the Irish annalists and the Irish bards are uniform and consistent and distinct in their notices of them. According to the Irish annalists, Fingal, son-in-law of Cormac, king of Leinster, was commander of the Fianna Eirinn, or Fians, a military race who existed at this time in Ireland. Fingal's palace was at Almhuin, or Allen, in Leinster, and he died in the year 273. In the reign of Cairbar, the son and successor of Cormac, this military class, or militia as they have been called, were put down by force in consequence of their dangerous presumption and the dissentions among their own body. 'They were attacked,' says Moore (*History of Ireland*, vol. i.), 'by the united force of almost all the royal troops of the kingdom (the king of Munster alone taking part with the rebellious Fians), and a battle, memorable for its extent of carnage, ensued, in which Osgar, the son of Oisin, or Ossian, was slain by the monarch's own hand.' This was the battle of Gabhra, which forms the groundwork of the poem of 'Temora.'

At this time, and for some centuries afterwards, the name of Scotia was exclusively applied to Ireland, and the name of Scoti, or Scots, to the inhabitants. They were a warlike race, who had conquered the greater part of Ireland, and gradually imposed their name on the island and its inhabitants. One of this race, Cairbar Riada, in the year 258, led over a colony of the Scoti from Ireland, and established them in Argyleshire. Riada had a territory in Ireland named Dalriada, and the district obtained by his colony was called Dalriada also. They had great difficulty however in maintaining their station against the power of their opponents the Picts, and it is uncertain whether they were not driven back to Ireland. But in the year 503 a larger colony was led over by Fergus MacErth, who established the kingdom of Dalriada, which afterwards obtained possession of the whole of the northern part of Britain, and imposed the name of Scoti on the inhabitants, and of Scotland on the country, as had previously been done in Ireland. Thus the Highlanders became connected with the Scots of Ireland, and through them derived their traditions of Fingal and Ossian.

It is not worth while to enter into evidences of forgery afforded by single circumstances and minor details in the various poems. Such evidences are in fact diffused through the whole of them, and meet us at every step, either in sentiments inconsistent with the rude state of society at the time, in the omission of every allusion to the dwellings, the dresses, the means of subsistence, and the superstitions of the inhabitants, as well as all mention, even incidentally, of animals which are known to have been in the country at the time. Such omissions could hardly have been made by a poet who was familiar with the manners and objects of that age, and was himself a party in the events which he describes.

To show the modern materials and workmanship of the poems, Laing has pointed out, in numerous passages, imitations of the Bible, and of Homer, Virgil, Milton, and others. Many of these imitations are obvious enough, but others are mere casual resemblances of phrases and words, which a genuine translator might have easily fallen into in rendering a real original.

The substance of Dr. Blair's 'Critical Dissertation on the Poems of Ossian' was originally delivered, soon after the first publication of 'Fingal,' in the course of his lectures as professor of rhetoric and belles-lettres in the university of Edinburgh. This Critical Dissertation, an elaborate composition of nearly pure nonsense, which expresses unbounded confidence in the genuineness of the poems, and bestows the most extravagant encomiums upon them as equal and in some respects superior to Homer, added to the natural astonishment that such poems should have been produced by a Gaelic bard in the third century, extended their fame not only throughout Great Britain, but over the whole continent of Europe; and France, Germany, and Italy vied with each other in enthusiastic admiration of them. This fever has in a great measure subsided, but Ossian has still his admirers, and the Dissertation, no doubt, its readers. To us it appears that almost everything which gives intrinsic value to other poems is wanting in these. We read them with almost uninterrupted incredulity. The characters represent a race of men which it is an absurdity to suppose ever to have existed. The events and incidents, so far as they are intelligible and there is anything approaching to detail, are such as we cannot even imagine to have occurred at any time or under any circumstances. All good poetry is distinguished by the truth and distinctness of its representations; and it has always been remarked of the greatest poets that they must have looked upon external nature and watched the workings of the human mind with the greatest diligence; and this appearance of truth is preserved not only in such poetry as represents the actual appearances of nature and the ordinary events of human life, but even in that more elevated poetry which passes beyond the bounds of reality. In Homer, with whom Ossian has been so absurdly compared, the scenes are perfectly panoramic; we never imagine that we are looking at a picture; the objects themselves are before our eyes; we are present at the events; the persons are known to us, with all their peculiarities, and we can trace their motives of action; when they express themselves in such or such a way, we can tell what passion it was that moved them, or what specific object they had in view. There is nothing of this kind in Ossian. Everything is vague and indistinct; the scenes are all confused; and the images, undefined as they are, seem to recur continually. Hence nothing is impressed upon the mind; nothing fixes itself upon the memory. There is no discrimination of character. We are informed indeed that some are old and some are young, some are generous and some cruel, but even these broad personal distinctions we should hardly have discovered from any peculiarity in their thoughts or manner of speaking. Every one expresses himself in nearly the same way, and a wearisome repetition of affected sentimentality pervades the whole.

Without something however of the substance of poetry, so high a reputation as these poems once had could hardly have been obtained. Macpherson was a Highlander, and had lived among mountain scenery from his infancy; and though many of his pictures, even of that scenery, are false, still there are sketches interspersed throughout all the poems which are true and beautiful.

But the great charm of Ossian's poems is in the language. A rich stream of harmony flows through all of them, which many are sensible of who are quite incapable of judging of the truth of the representations or the propriety of the thoughts. Sir Walter Scott, in a letter to Anna Seward, says, 'Most Highlanders, after they have become complete masters of English, continue to think in their own language; and it is to me demonstrable that Macpherson thought almost every word of Ossian in Gaelic, although he wrote it down in English. This gave a great advantage to him in forming the style of Ossian, which, though exalted and modified according to Macpherson's own ideas of modern taste, is in great part cut upon the model of the tales of the sennachies and bards.' M'Culloch, in his 'Letters from the Highlands,' addressed to Sir Walter Scott, expresses an opinion somewhat different, and remarks, that the original poems were in verse, and that a great part of their beauty must have been lost in a prose translation. If he had examined that prose with attention, he would have found a most careful rhythmical elaboration of refined English, with which the rude versification of any poem ballads which exist either in Irish or Erse would not bear a comparison. Indeed as a specimen of rhythmical prose we have nothing equal to the Ossianic poems in our language. Every part is, in this respect, worked up with extreme care; there are whole lines following consecutively of measure nearly pure, but generally intermixed with other measures in such a manner as to produce an effect extremely pleasing. The sentences also are very short, which affords the means of adjusting the pauses so as to conceal the obviously versified structure which the lines would have otherwise assumed; and to add to the attraction of this 'measured prose,' poetical epithets and phrases, drawn from poets ancient and modern, are scattered lavishly over the whole.

OSSIFICATION is the formation of bone. The natural process is already considered in the article BONE, and that by which injuries are healed in the article FRACTURE. Preternatural ossification is observed in several tissues of the body. It is most frequent in the cartilages of the ribs, in which it almost constantly occurs in advancing years. In most persons bone begins to form in these parts after the fiftieth year; it sometimes commences between the ages of thirty and forty, but is often delayed to a much later period; and Harvey relates that in the body of Thomas Parr, who died in his 153rd year, the cartilages of the ribs were still flexible and soft. The change is generally earlier in men than in women, and it affects the cartilage of the first rib sooner than the rest.

Next to the cartilages of the ribs those of the windpipe are most liable to become osseous. Ossification of the cartilages of the ear, nose, and Eustachian tube is, on the contrary, extremely rare, and in the few cases in which it occurs it is not particularly connected with old age. The cartilages of the moveable joints never ossify.

The tendinous tissue is that which, next to the cartilaginous, is most subject to ossification. This change is not uncommon at the insertion of the tendons of muscles that are much exerted, and in the ligament of some fixed or slightly moveable joints. Small pieces of bone are also not unfrequently formed in the dura mater [BRAIN]; and these are one of the sources of incurable epilepsy. Bone is also sometimes formed in the fibrous coats of the spleen and liver.

Ossification occasionally takes place in the false membranes produced by acute inflammation of the pleura, and more rarely in those of the pericardium; and it is a common process in the adhesions which form between the heads of bones exposed by ulceration of their cartilages, producing the most fixed kind of anchylosis of the joints.

A few remarkable cases are recorded of ossification of the muscles. There is a skeleton in the museum of the College of Surgeons in London, in which it has taken place to such an extent that nearly all the bones must have been immoveably fixed by the transformation of the tissues by which, in the healthy state, they are moved. In equally rare cases the crystalline lens, the vitreous humour [EYE], and some other parts, are found converted into bone.

In all these examples the material formed exactly resembles true bone in its minute structure and chemical composition. In other cases, as in ossification of the heart and arteries, the substance deposited is composed of carbonate and phosphate of lime, as bone is, but its particles have no definite arrangement. That which is called ossification of the heart is not an affection of the proper substance of that organ, but of its valves, in which earthy matter is sometimes deposited, so as to render them stiff and unyielding, and destroy the pliancy which is necessary for the performance of their functions. A deposition of earthy matter in any part of the substance of the heart itself is among the rarest diseases, but such cases are on record. [HEART, DISEASES OF.]

The disease named ossification of the arteries consists in the deposition of plates or rings of hard earthy substance in their middle elastic coats. This deposition is preceded by that of a peculiar soft opaque yellow substance, which becomes gradually hardened. The deposition of this yellow substance in the large arteries is so common that it is very rare to meet with the body of an adult in whom it has not taken place to a greater or less extent; and it not unfrequently commences in early childhood. The change to earthy matter does not commonly take place before the thirtieth year, and is very general after the sixtieth. The stiffness and irregularity which it produces in the large arteries, the ulceration of their lining membrane which often accompanies it, and the dilatation consequent on their loss of elasticity, are common causes of dyspnœa and dropsy. The same changes are frequent in the arteries of the legs, and the obstruction to the circulation which they produce generally gives rise, if life is sufficiently prolonged, to the affection called gangræna senilis. [ARTERIES, DISEASES OF.]

OSSORY, an Irish bishopric, included in the ecclesiastical province of Dublin. The diocese is bounded on the north by that of Kildare, on the north-east and east by that of Leighlin, on the south-east by that of Ferns, on the south by that of Waterford, on the south-west by that of Lismore, on the west by that of Cashel, and on the north-west by that of Killaloe. A small portion of the diocese is detached from the main part, and is surrounded on the north by the bishopric of Meath, and on all other sides by that of Killaloe. The extreme length of the diocese of Ossory from north to south is given by Dr. Beaufort (*Memoir of a Map of Ireland*) and by the Ecclesiastical Commission (*Parl. Papers* for 1837, vol. xxi.) at 36 Irish or 46 English miles; the breadth at 23 Irish or 29 English miles; and the area, by Dr. Beaufort, at 346,000 Irish or 555,000 English acres. By taking the length in the direction from north-north-west to south-south-east the length is 49 Irish or 61 or 62 English miles, and the breadth 17 Irish or 22 English miles. The diocese comprehends nearly the whole county of Kilkenny, a good part of Queen's County, and a small portion of King's County. It takes its name from a district, not from a town.

The bishopric was founded early in the fifth century, and was established in the first instance at Saigur, now Seikyran or St. Kyran, a parish which forms the detached part of the diocese mentioned above. It was afterwards removed (A.D. 1052) to Aghaboe or Aghavoe, in the barony of Upper Ossory in Queen's County, and finally (near the close of the twelfth century) to the borough of Irishtown, which forms part of the city of Kilkenny. The cathedral, dedicated to St. Canice, is a large and handsome pile, built in the twelfth and thirteenth centuries. It is in the form of a cross, chiefly of early English architecture, with a low massive tower at the intersection of the nave and transepts. [KILKENNY, CITY OF.] The cathedral establishment comprehends a dean, precentor, chancellor, treasurer, and archdeacon, seven prebendaries, and three vicars choral. The bishop has a good house close to the cathedral.

The gross yearly income of the bishopric, on the average of three years ending 1831, was 3859*l.* 0*s.* 6¾*d.*, the net income for the same period 3322*l.* 11*s.* 0¼*d.* The lands belonging to the see comprise 21,730 statute acres of profitable land. The bishop presents to the dignities and prebends in the cathedral, and to twenty-two other benefices.

The number of parishes in the diocese was given by Dr. Beaufort (A.D. 1792) at 136; the number of benefices at 56; of churches at 36; and of glebe-houses 12. By the Fourth Report of the Ecclesiastical Commissioners (*Parl. Papers* for 1837, vol. xxi.) the number of parishes was given at 128, the number of benefices at 59; 32 of them single parishes and 27 unions. Of the 59 benefices, only 46 had churches; there were three chapels-of-ease; making 49 places of worship of the establishment, capable of accommodating 9170 persons. The population of the diocese in 1834 was estimated by the Commissioners of Public Instruction at 222,325; viz. 12,361 members of the established church, 209,848 Catholics, 8 Presbyterians, and 108 other Protestant dissenters. The number of places of worship by the First Report of the Commissioners (*Parl. Papers* for 1835, vol. xxxiii.) was 55 for the establishment (of which 52 were churches), 94 for Catholics, and 4 for Protestant dissenters. The Presbyterians had no meeting-house in the diocese. The number of benefices as well as of churches slightly varies in this Report from that quoted above. The proportion of the members of the establishment to the whole population was little more than half the average proportion in the whole of Ireland; that of the Catholics materially above the average; that of Presbyterians and other Protestant dissenters very much below the average.

The number of day-schools in the diocese, according to the Second Report of the Commissioners of Public Instruction (*Parl. Papers* for 1835, vol. xxxiv.) was 308; of which 229 were wholly supported by payments from the parents of the children, and 68 wholly or in part by endowment or subscription; 18 of these were in connection with the National Board of Education. The total number of children at school was computed at 20,976; of 18,868 children contained in the schools from which returns were made, 11,449 were boys, 7196 girls, and of 221 the sex was not specified. The computed proportion of children at school to the total population was 9·44 per cent., being considerably above the average of Ireland.

This see has been united, by virtue of the Act 3 & 4 Will. IV., to the adjacent sees of Leighlin and Ferns.

OSTADE, ADRIAN VAN, was born in 1610, in the city of Lübeck; but though a German by birth, he is always considered to belong to the Dutch school, having formed his style in Holland, where he studied under Frank Hals, and is said to have received some instruction from Rembrandt. In the school of Frank Hals he formed an acquaintance with Brouwer, who became his intimate friend and adviser. Like Brouwer, he chose his subjects from low life, such as farm-houses, stables, and the interior of alehouses; the figures are generally occupied in drinking, smoking, and the like; rural sports, village weddings, and countrywomen engaged in their domestic employments, were the scenes and the characters with which he was familiar. But though in the choice of his subjects he had no regard to elegance, and though he took what he had before him, without endeavouring to improve it, his compositions are so spirited, there is such truth, nature, and life in his little pictures, there is such delicacy in his pencil, such warmth, transparency, and brilliancy in his colouring, and such a profound knowledge of the chiaroscuro, that it is impossible not to admire his genius and execution. The following is the character given of him by Fuseli:—

'Adrian van Ostade, more properly than any other Dutch, Flemish, or German artist, may be said to have raised flowers from a dunghill. He has contented himself to trace the line which just discriminates the animal from the brute, and stamps his actors with instinct rather than with passions. He has personified the dregs of vulgarity, without recommending them by the most evanescent feature of taste, and yet decoys our curiosity to dive with him into the habitation of filth, beguiles our eye to dwell on the loathsome inmates and contents, and surprises our judgment into implicit admiration, by a truth of character, an energy of effect, a breadth and geniality of touch and finish, which leave no room for censure. If he is less silvery, less airy than Teniers, he is far more vigorous and gleaming; if his forms be more squat and brutal, they are less fantastic and more natural; if he groups with less amenity, he far excels the Fleming in depth and real composition.'

Ostade's figures were so much admired, that he was frequently solicited by the most eminent contemporary artists to paint the figures in their landscapes. His best works are extremely scarce and sell at very high prices. Dr. Waagen, in his valuable work 'On Art and Artists in England,' describes several of Ostade's works in the collections of Sir Robert Peel, Lord Ashburton, Mr. Hope, his late Majesty George IV., Mr. Beckford, and in the Bridgewater and Dulwich galleries. Ostade died in 1685, at the age of 75.

OSTADE, ISAAC VAN, born at Lübeck in 1617, was the brother of Adrian, from whom he learned the art of painting, and whose manner he imitated so closely that some of his copies after Adrian have been frequently ascribed to the latter. He died young, which hindered him from acquiring the excellence that he would probably have attained. He is generally characterised as much inferior to his brother, but Dr. Waagen, after carefully examining his pictures in the collections in England, says of him:—'Great injustice is done to Isaac van Ostade by the poor pictures of country life which are frequently ascribed to him in the galleries in Germany. In Holland, in Paris, and above all in England, we may be convinced that in his village scenes and in his winter-pieces he is a wholly original master, and by no means inferior to his brother.' The Doctor then proceeds to describe in terms of unqualified admiration a picture by Isaac (1 foot 9 inches high and 1 foot 6 inches wide) in the collection of Sir Robert Peel, who paid 400 guineas (not 4000, as it stands both in the German and the English, through a typographical error) for it—a price which the Doctor thinks reasonable in comparison with others. Dr. Waagen describes other capital pictures by Isaac van Ostade at Lord Ashburton's, in the Bridgewater Gallery, and in the private collection of George IV.

OSTEND (properly written *Oostende*), a fortified town seaport of West Flanders, in 51° 14′ N. lat. and 2° 54′ E. long., 12 miles west from Bruges and 25 miles east-north-east from Dunkirk. The town is clean and well-built. In 1834 it contained 1403 houses, 57 streets, and 5 squares, 3 churches, 6 schools, a prison, an hospital, and a town-hall, which is a large and plain but handsome building; the population is 11,390. The town stands upon a plain, and is entered by four gates. Of late years it has been much frequented during the summer as a watering place; the sea-bathing is good, and there are excellent baths. The ramparts form an agreeable promenade.

Ostend has great facilities for carrying on trade with the interior by means of canals. The Ostend and Bruges canal is of sufficient dimensions to allow the largest Indiamen to pass through it. The Nieuport canal terminates at Ostend; and by the canal from Bruges to Ghent, which is a continuation of the cutting from Ostend to Bruges, and which communicates with the Schelde, Ostend is connected with the heart of the kingdom of Belgium. This town has recently been rendered of more importance by the system of railroads established in Belgium, by which it is intimately connected with Bruges, Ghent, Courtray, Termonde, Malines, Brussels, Antwerp, Louvain, Tirlemont, and Liége. By means of these works passengers landing at Ostend may reach Liége in six or seven hours. The communication with England is kept up by steam-vessels, which leave London and return twice in every week, performing the voyage in about 14 hours.

The number of vessels that arrived and cleared from the port in each of the years from 1833 to 1836, was as follows:—

	Inwards.				Outwards.			
	Loaded.		In Ballast.		Loaded.		In Ballast.	
	Ships.	Tons.	Ships.	Tons.	Ships.	Tons.	Ships.	Tons
1833	865	90,845	16	1,732	670	61,129	365	42,428
1834	519	54,183	37	2,995	425	45,087	127	13,038
1835	521	55,735	28	2,194	433	46,925	125	11,523
1836	505	56,963	12	763	364	38,205	169	20,468

The imports consist chiefly of colonial produce, wool, wine, and British manufactured goods: the exports are, agricultural produce, linens, leather, oak bark, tallow, and salt.

Ostend was a small village in the ninth century, but two centuries later the port was much frequented. Old Ostend was destroyed by the sea in 1334. In 1372 the present Ostend was merely a fishing-place. It was enclosed with walls by Philip the Good in 1445, but was not regularly fortified until 1583 by the prince of Orange. The Dutch sustained a siege in this town against the Spaniards, which began in 1601 and lasted until 1604, when it surrendered by capitulation. It is said that the besieged lost during this time 50,000 men, and that the loss of the Spaniards was even more considerable. The town was taken by the allies in 1706, and in 1715 it was ceded by Holland to the emperor of Germany. Louis XV. took it in 1745, after a siege of 18 days, in which the town was greatly injured, and restored it in 1748. In 1794 it was taken by the French, and remained in their possession until 1814, having been unsuccessfully attacked by the English in 1798. Little trade was carried on during the war, but many privateers were fitted out from the port.

OSTERSUND. [SWEDEN.]

OSTERVALD, JEAN FRÉDERIC, born at Neufchâtel in Switzerland, in the year 1663, studied at Saumur, Orléans, and Paris, after which he returned to his native country, and in 1699 was appointed pastor of the Reformed church of the town of Neufchâtel. He became noted for his zeal in instructing his flock, as well as for his theological learning. He published an edition of the Bible in French, with arguments or explanatory heads to the books and chapters, which became very popular among the French Protestants under the name of 'Ostervald's Bible,' and of which there have been several reprints. He published also, 1, 'Abrégé de l'Histoire de la Bible;' 2, 'Traité des Sources de la Corruption qui règne aujourd'hui parmi les Chrétiens;' 3, 'Traité contre l'Impureté;' 4, a Catechism which is much used in the French Protestant churches, and is known by the name of 'Catéchisme d'Ostervald;' 5, 'Ethica Christiana;' and other religious works. Ostervald died at Neufchâtel, in 1747, much regretted. He and his two friends, J. A. Turretin of Geneva and Samuel Werenfels of Basel, did much toward the revival of religion in Switzerland; they were styled the 'Triumvirate of Swiss Divines.'

OSTIA, OSTIUM TIBERINUM, the name of the former port of Rome, situated at the southern mouth of the

Tiber, is 14 miles from the capital. The ancient town of Ostia, which was situated below the fork of the river, spread in a semicircular form along a bend made by the left or southern branch, on a piece of ground slightly elevated above the surrounding sand and marshes. Ostia was founded by Ancus Marcius, according to Strabo. It stood on a narrow peninsula between the river and the Lacus Ostiae, now Stagno di Levante, which formerly communicated with the sea, but is now separated from it by a considerable tract of sand. The port appears to have been a mere anchorage, near the site of the modern Torre Bovacciana, in which the Roman fleet used to be moored. It was open however and unprotected, for we read in Cicero (*Pro Lege Manilia*, xii.) that the Cilician pirates captured and plundered the fleet moored there, to the great disgrace of the Roman name. This anchorage ground has long been filled up with sand, and the sea is now nearly two miles from old Ostia. Strabo (p. 231, Casaub.) describes Ostia as having no port, and he says that the mouth of the river had become so choked up that only small vessels could ascend the stream. Rutilius Numatianus (A.D. 420) informs us that the southern branch of the Tiber was become impassable on account of the sand, but that small boats could still enter it. In the previous century Minucius Felix speaks of Ostia as being a very agreeable residence, with a mild climate and perpetual verdure. In the time of Procopius, about the middle of the sixth century, Ostia was in a ruined state and nearly deserted. The site is now marked by heaps of ruined buildings, which cover a considerable space, but are mere shapeless masses of small stones held together by cement. Excavations have been made and some statues and inscriptions have been found. There are some remains of a temple and of a theatre. Poggio, in the narrative of his journey to Ostia with Cosmo de' Medici, addressed to his countryman Niccoli, complains of the devastation committed in his time; he saw people employed in turning a temple of marble into lime.

The ports of Ostia being filled up and the southern branch of the river having become impassable for vessels, Claudius, and after him Trajan, thought of supplying Rome with a new port near the right or northern mouth of the river. The port of Trajan, which was destroyed by Totila, is now become a stagnant lagune, the sea having retired nearly two miles on that side also. There are some remains of the walls and aqueduct, and the place retains the name of Porto.

In the middle ages Ostia somewhat revived. In the fourteenth century it was occupied by Ladislaus, king of Naples. It was fortified by Sixtus IV., who built the castle. The French, who had seized it, were driven away by Cardinal della Rovere, afterwards Julius II., whose trophies are still in the cathedral. There are now about 100 inhabitants at Ostia in winter and about ten in summer. There is a small cathedral in good taste, a bishop's palace, and a few other habitable buildings. The castle or fort of Ostia consists of three or four lofty but ruinous brick towers joined by a curtain and surrounded by a ditch.

(Gell's *Topography of Rome and its Vicinity*, and *Map accompanying it*; Valery, *Voyages en Italie*.)

OSTIAKS. [SIBERIA.]

OSTRACEANS. [OYSTERS.]

OSTRACISM, the name for a singular institution existing for some time among the Athenians. When any man became conspicuous by wealth or by power, from whatever source derived, and was in consequence thought likely to entertain plans of ambition dangerous to the public peace and the stability of the existing form of government, this institution enabled the Athenian people to send him for a time into exile, and thus rid themselves of the danger which they dreaded. It was done as follows:—When the occasion was thought to require it, a day was fixed at an ordinary meeting of the Athenian people, for the purpose of holding an *Ostracism*. On that day a part of the market-place (*ἀγορά*) was railed in, ten different approaches being left to the part thus railed in. There was thus one approach for each of the ten Athenian tribes. By these approaches the citizens, distributed according to their tribes, entered the space within the rails, and there deposited, in urns provided for the purpose, their shells or bits of earthenware (*ὄστρακα*, *ostraca*, whence the name *Ostracism*), marked with the name of the person whom they respectively thought it desirable to banish. The nine archons, together with the Boulê and Prytanes, superintended, seeing that everything was done properly, and in the end counting the votes. First of all they counted the gross number, which it was necessary should be above six thousand, else there was no valid Ostracism. (Plutarch, in *Vit. Aristid.*) If there were found to be six thousand votes, then they proceeded to count the numbers against different individuals; and according to the account given by Plutarch, which, differing from another account, seems the more probable of the two, the individual against whom there was the greatest number of votes was straight sentenced to ten years' banishment, or (changing the phrase) was *ostracised*. The other account, for which the Scholiast on Aristophanes, and Pollux, are the authorities, says it was necessary that there should be six thousand votes against the individual ostracised, and that a mere majority short of six thousand was not sufficient. Whichever of these two accounts is adopted, the person who was ostracised was obliged to leave Athens within ten days after the sentence, and unless a vote of the people recalled him before the expiration of that time, to stay in exile for ten years. The goods of the ostracised person were not confiscated; neither was Ostracism considered in the light of a punishment or accounted a disgrace. It passed for what it was, a declaration of superior wealth, of superior influence, sometimes indeed of superior virtue, whose ascendency the state dreaded.

It is well known that Aristides the Just was one of those on whom Ostracism was inflicted. The story told by Plutarch of his writing down his own name for Ostracism is also well known.

The precise time at which the institution of Ostracism was introduced is not known. It is generally believed that it was introduced by Cleisthenes after the expulsion of the Peisistratidae (Ælian, *Var. Hist.*, viii., c. 24); and it has been said also that Cleisthenes was the first victim. This however does not rest on very good authority. The first person ostracised was most probably Hipparchus, a relation of Peisistratus; the last was Hyperbolus.

As to the merits of such an institution as Ostracism, there cannot be any great difference of opinion. That must be a bad form of polity which needs it, though under a bad form of polity it may be itself a good. The first object of the statesman is to construct a government proof against the wealth and power arising from the ordinary course of social development: if he fails in this, he must defend the government even at the expense of partial evil. The Athenians took care to mitigate the severity of the banishment, so far as they could consistently with the object of it. 'Though this institution,' says Montesquieu, 'may be so far a condemnation of popular governments, yet it is, on the other hand, well fitted to prove their mildness; and we should have perceived this, were it not that, exile being with us always a punishment, we have been unable to separate the idea of ostracism from that of punishment.' (*Esprit des Lois*, book xxi., chap. 17.)

A similar institution is said to have prevailed in Argos, Miletus, and Megara. At Syracuse also it prevailed, and there bore the name *Petalism*, leaves (*πέταλα*) being used on the occasion of voting, instead of shells.

OSTRA'CODA. [BRANCHIOPODA, vol. v., p. 241.]

O'STREA. [OYSTERS.]

OSTRICH. [STRUTHIONIDÆ.]

OSTROGOTHS, or Eastern Goths, a division of the great Gothic nation, were settled in Pannonia in the fifth century of our æra, from whence they extended their dominion over Noricum, Rhætia, and the Illyricum. [GOTHS.] About the year 482 or 483 A.D., their king Theodoric was serving as an auxiliary under the emperor Zeno, and distinguished himself in Syria. On his return to Constantinople, Theodoric, according to the statement of the historian Evagrius, fearing Zeno's jealousy of his success, retired into Pannonia in 487, where he collected an army, and in the following year marched into Italy, with all his tribe, men, women, and children, and, as appears, with the consent of Zeno himself, who wished to remove the Ostrogoths from his territories: he defeated Odoacer in various battles, took him prisoner, and some time after put him to death. Upon this event Theodoric sent an ambassador to Anastasius, the emperor of Constantinople, who sent him in return the purple vest, and acknowledged him as king of Italy. It appears that both Theodoric and his predecessor Odoacer acknowledged, nominally at least, the supremacy of the Eastern emperor. For the rest of the history of the Ostrogoths see THEODORIC, who established his dynasty over Italy, which is generally styled the reign of the Goths in that country.

OSTRO'PODA. [BRANCHIOPODA, vol. v., p. 241.]

OS'TRYA, or Hop Hornbeam, derives its English name from its inflorescence consisting, in the female, of scales packed closely over each other so as to resemble very much the head of a hop, and to its foliage being similar to that of the hornbeam. Two species are known: the one, *O. vulgaris*, a native of the South of Europe; the other, *O. virginica*, of the United States; these are possibly mere varieties of each other. They both form handsome deciduous trees, usually of small size, but sometimes acquiring a height of 60 feet. For figures and a more particular account, see Loudon's *Arboretum Britannicum*, p. 2015, fig. 1939 and 1940.

OSU'NA, a town in the kingdom or province of Sevilla, in Spain, situated in 37° 17′ N. lat. and in 5° 9′ W. long. It is above 40 miles from the city of Sevilla, and situated on one side of an extensive plain, at the foot of an eminence which is crowned by a church. The town is semicircular in form, and is of considerable size; it contains above 2300 houses, and 16,000 inhabitants. It has one parish church and a collegiate church, fourteen convents (suppressed in 1835), and eight hermitages; it has also four hospitals, two barracks, ten large inns, and a public granary. The university, which was celebrated in the time of Cervantes, was abolished by royal decree in 1824. The town is neat and pretty, and has some fine promenades and shady orchards in its immediate vicinity; it is deficient in good water. The climate is salubrious, except during the heats of summer, when, according to Miñano, the thermometer sometimes reaches 35° of Réaumur (110¾° Fahr.), and rises even higher when the wind is easterly. Some small lakes, a few miles to the north of Osuna, at that season also infect the air in their neighbourhood with nexious exhalations.

The population of Osuna is almost entirely agricultural; the only manufactures are mats, ropes, and baskets from the *esparto* rush (stipa tenacissima). The vast plain in which it stands is said to be the most fertile grain district of Andalucia. Barley and olive oil are the principal products, but it yields also much wheat, beans, peas, lentils, and other pulse, some wines of inferior quality, excellent capers, which are preserved with salt and sent to the neighbouring cities and even to America, and abundance of the coccus ilicis and reseda luteola, used in dyeing. It contains also large pasture-grounds, on which numerous horses, horned cattle, and swine are reared. The annual contribution of Osuna to the royal treasury exceeds 4000*l*.

Osuna is of very remote origin. Conde says it was anciently called Urso. Many Roman remains are still found in the town. The Arabs called it Oshuna.

(Miñano; Conde, *Aledris*.)

OSWEGO. [CANADA.]

OSWESTRY, a corporate town in the parish and hundred of Oswestry and county of Salop, 16 miles north-west from Shrewsbury, 160 north-west from London (direct distances), and on the road from London to Holyhead. 'On this spot,' says Pennant, 'celebrated in Saxon history and legendary piety, on August 5, 642, was fought the battle between the Christian Oswald, King of the Northumbrians, and the pagan Penda, King of the Mercians. Oswald was defeated and lost his life. The barbarian victor cut the body of the slain prince into pieces and stuck them on stakes dispersed over the field as so many trophies. . . . . From the fate of the king the place in aftertimes was named Oswald's Tree, now Oswestry. (*Tour in Wales*, London, 4to., 1778, pp. 246-8.) The miracles reputed to have been wrought by means of the earth taken from the field in which the remains of the prince were interred, are detailed by Bede in his 'History of the Primitive Church,' and occupy several pages of that work (Hurst's *Translation*, London, 1814, iii., chap. 9-13).

Oswald was admitted by the Romans into the list of their saints, and a church was raised to commemorate his martyrdom. In the corporate seal he is represented in his robes, holding a sword in his right hand and an oak-branch in his left; above, are the words, 'De Oswaldatre sigillum commune.' In the vicinity of the town, at a place called by the Welsh 'Cae Naef' (Heaven's Field), there is a remarkably fine spring of water, which bears the name of Oswald's Well, and over which, as recently as the year 1770, were the ruins of a very ancient chapel, likewise dedicated to him.

The first charter was granted to the town in the reign of Henry II., by William earl of Arundel, the lord of the manor. The son of this nobleman having taken part with the barons against King John, the latter (1212) marched upon the town and reduced it to ashes. A similar fate befel it, about a century afterwards, at the hands of Llewellyn, prince of North Wales, and it continued to suffer from border-warfare until Edward I., in 1277, ordered it to be surrounded by a wall and ditch. Some portions of this wall are yet standing, but the four gates were removed in 1769. The charter of Richard II., granted in 1397, after the attainder and execution of Richard earl of Arundel, exempts the burgesses from all customs throughout the kingdom, the liberty of the city of London excepted; and among other privileges acquired by them during this reign, was that of compelling the inhabitants of the eleven towns within the hundred to bring their cattle, corn, victuals, and wares for sale in the market-place of Oswestry before sending them to any other market or fair. The lord's Welsh tenantry of the hundred were also bound by their tenure to keep watch and ward for three days and three nights at the gates of the town during the fairs of St. Andrew and St. Oswald, but instead of protecting they were found to ravage and plunder the place, whereupon they were dismissed from that duty and compelled to pay a sum of money to Englishmen for the safe custody of the town. (Pennant, p. 257.)

The boundary of the present municipal borough extends about two miles east and west of the town, and half a mile north and south, and is divided into two wards. The governing body is composed of 6 aldermen and 18 councillors. The town is paved and lighted under a local act, and is increasing in extent, particularly on the English side. It contains a town-hall and a small gaol, erected in 1825. The church, erected since 1616, is spacious and surmounted by a plain tower. The vicarage is in the diocese of St. Asaph and patronage of Earl Powis, and yields an annual net revenue averaging 477*l*. The trade of the town is facilitated by the Ellesmere canal and the Llanymynech branch, which pass within four or five miles. The manufactures are chiefly coarse linens and woollens. The market-day is Wednesday, and fairs are held in March, May, June, August, and December. The population of the town, in 1831, was 4478, and that of the entire parish 8581.

By an Act of 33 Geo. III., all the parishes within the hundred of Oswestry, with the exception of the parish of Melverly, are incorporated for affording relief and employment to the poor, and a spacious house of industry has been built in the vicinity of the town. The number of inmates, in 1831, was 273. There is a free grammar-school, national school, and Sunday-school. In the national school there are from 230 to 240 boys, and from 150 to 170 girls, all of whom receive daily instruction. The grammar-school was founded by David Holbetche or Holbeck, prior to the year 1634. It is open to all boys born within the parish who are able to read. The average number of scholars upon the foundation has not for many years exceeded fifteen. In addition to these the master usually has about twenty pay boarders. Much of the property belonging to the charity has probably been lost, and that from which the present revenue is derived, amounting only to 268*l*. 11*s*. 6*d*., appears to have been recovered with difficulty. There are other smaller charities in this place.

(Camden's *Britannia*; Price's *History of Oswestry*, 8vo, 1815; *Twenty-Fourth Report of the Commissioners on Charities for* 1831, vol. ii., pp. 424-36.)

OSYTH, ST. [ESSEX.]

OTAHEITE, or more properly *O Tahiti*, is the largest of the Society Islands, a considerable group situated in the Pacific Ocean, between 16° and 18° S. lat. and 1[illegible]° and 153° W. long. Otaheite is about 35 miles long, and more than 130 miles in circumference. It consists of two peninsulas, of unequal extent, united by a low isthmus, somewhat more than 3 miles wide. The north-western and larger peninsula is called Opureone or Tahiti-nue (Great Tahiti), and the south-eastern Tiarrabooa, or Tahiti-iti (Little Tahiti). The surface is estimated to be about 430 square miles, or equal to the county of Bedford. The island is surrounded at a distance of from 3 to 6 miles by a coral-reef, which has several breaks, and affords many good anchorages, as the sea within the Opureone is not agitated by the winds. The most remarkable are, Mattaway Bay, near the north-eastern extremity; Soanoa Harbour, four miles westward of Mattaway;

and Papara towards the north-western extremity of the island, which is now most frequented by European vessels. The interior of both peninsulas is occupied with mountain masses, which terminate in high and sharp peaks. The most elevated of these peaks, called [illegible], rises to between 7000 and 8000 feet above the sea-level; it is nearly in the centre of the larger peninsula. Some of the summits of the smaller peninsula are nearly as high. Except these peaks, the whole island, especially the lower hills, is covered with thick woods. The hills extend from the centre of the peninsula in all directions towards the shores, and approach them in some places within less than half a mile, enclosing level valleys, which extend 5 or 6 miles inland, to the foot of the high rocky masses. These valleys are watered by fine streams, on the banks of which, as well as on the shores of the sea, are built the dwellings of the inhabitants. Lava, basalt, and pumice-stone, which occur in several places, seem to indicate that this island, like all the elevated islands of the Pacific, owes its origin to volcanic agency.

The climate is very mild, the difference of temperature in the winter and summer months being inconsiderable. It is also very healthy, except during the rains, which occur from the beginning of December to the end of February, but even then diseases are not frequent. The productions are numerous, especially the plants which supply food for man. The bread-fruit trees and cocoa-palms are regularly planted, and batatas, yams, taro, and bananas are cultivated with care; the sugar-cane, which is of excellent quality, tobacco, and some other tropical plants are also cultivated. Cotton and indigo are only cultivated by the Europeans, the natives being too indolent to bestow the necessary labour on them. Several wild plants also afford food, especially the arrow-root, which is collected in May, and a considerable quantity of which is exported; there are also the casuarina-tree, a kind of [illegible], and figs. Cloth is made, as in other islands of the Pacific, of the inner bark of the bread-fruit tree, the paper mulberry-tree, and the hibiscus; of the last also ropes are made. Oil is extracted from the cocoa-nut. The interior produces timber in great abundance. Forests cover all the mountains of Tiarrabou, and the southern declivities of those of [illegible]. Some vessels have been built of the timber. When the Europeans first visited the island, the only domestic animals were pigs, dogs, and fowls. The missionaries have introduced cattle, horses, sheep, and goats. The cattle and goats thrive, but the sheep and horses do not succeed so well. Wild birds are numerous, especially pigeons, ducks, and several kinds of parrots.

Otaheite was discovered in 1606, by the Spaniard Quiros, and called Sagittaria, but as his description was not correct, Captain Wallis, who visited the island in 1767, considered it as a new discovery and called it King George's Island; and Bougainville, who visited it in the following year, named it Nouvelle Cythère. Cook, who visited it between 1769-78 several times, gave it the native name, and published a very interesting account of the island and its inhabitants. He estimated the population at 200,000. After having been visited by several other navigators, missionaries were sent there to convert the islanders, in 1797. They found the natives, as they had been described, friendly to strangers and devoid of all treachery; but they discovered that several immoral practices existed among them, as infanticide and human sacrifices. There were also continual wars among them. For fourteen years the labours of the missionaries were fruitless, and they were treated with contempt. But in [illegible] the king of the island, Pomaree II., embraced Christianity, and introduced it among the natives. After his death (1821), during the minority of his son, the missionaries acquired a greater influence, and by their advice a constitution was formed, and written laws were made (1825); but as neither the constitution nor the laws are understood, and are not founded on the customs and usages of the natives, they are entirely neglected. The introduction of Christianity has however effected the abolition of infanticide, of human sacrifices, and other immoral practices; it has also established peace. Before the son of Pomaree attained the age of manhood, he died, and was succeeded by his sister the queen Aimata. The government is a despotism; the sovereign possesses absolute power over the land, and may by an order deprive any chief or person of his landed property; each chief also possesses the same absolute power over the land of each individual who lives in his district. The missionaries assert that, according to a census taken several years ago, the population did not exceed [illegible] souls, and they attribute the great decrease to the venereal disease, which was introduced by Europeans, to the continual wars, and to infanticide. The natives belong to the Malay race, and speak a language which may be considered as a dialect of that widely spread language. They have made some progress in civilization, as is shown by their manufacture of cloth, called *tappa*, their boats, which are large enough to carry 150 persons, their dwellings, and several utensils. But they have still profited little by the presence of the missionaries, the churches being built of wooden frames filled with wattled hibiscus, and covered with a compost of sea-sand and lime, which again is whitewashed. The culture of their fields and gardens has also not materially changed. It cannot be said that there exists a commerce, as there is no currency. Small quantities of cocoa-nut oil, arrow-root, timber, and sugar are bartered for ribbons, cloth, &c., and these are the only articles which are exported. (Cook's *Voyages*; *London Geogr. Journal*, vols. i., iii., v.)

OTA'RIA. [Seals.]

OTHMA'N (*Ibn Affán*), the third khalif of the Moslems after Mohammed, was a direct descendant from Abd-al-menaf, one of the ancestors of the prophet. Having early adopted Islám by the persuasion of Mohammed, he became one of his most zealous *sahábi* (companions), followed him in his flight from Mecca to Medina, and was made, on his return, one of his most confidential friends and secretaries. [Mohammed.] Othman was one of the six individuals to whom the khalif Omar had by his will entrusted the designation of a successor. After mature deliberation, the majority chose Othman, on condition that he would govern the people according to the rules of the Korán; Othmán solemnly promised to do this, and he was accordingly invested with the supreme power towards the end of Dhí-l-hajjah, A.H. 23 (Nov. or Dec., A.D. 644), three days after the death of Omar. His first public act was to send a body of troops under Al-mughayrah Ibn Shaabah to complete the reduction of the province of Hamadan (A.D. 645), while another army expelled Jezdegerd from Persia (A.D. 646). [Omar.] Another body of Arabs (A.D. 647) reduced all that part of Khorassán which had escaped former invasions. In the meanwhile Abdullah Ibn Said invaded western Africa, and, after defeating and killing at Yakúbiyyah the patrician Gregorius, who commanded in the Grecian emperor's name, subdued its principal cities. Four years afterwards (A.D. 651) the same commander made an incursion into Nubia, and obliged the Christian sovereign of that country to sue for peace and pay him tribute. The islands of Cyprus and Rhodes were attacked and plundered by Muawiyah Ibn Abí Sufyán (A.D. 648): these two maritime expeditions being the first which the Arabs ever made. While the Mohammedan empire was thus extending on all sides, Othmán was rapidly losing the affections of his subjects by the weakness of his internal administration and his partiality towards the members of his family. Abú-l-feda, the Arabian historiographer, says, that some one having suggested to Omar on his death-bed to appoint Othmán his successor, he exclaimed, 'God forbid that I should; Othmán is too much inclined to favour his own friends and relatives.' In this judgment Omar was not mistaken. Othmán began by removing the celebrated Amrú Ibn Al-ass from the government of Egypt—a country which he had conquered—and appointing in his place his own foster-brother Abdullah Ibn Said. This measure was as disagreeable to the Arabs as to the Egyptians. The people of Alexandria, who bore impatiently the Mohammedan yoke, and were only kept in obedience by the mildness and the justice of their governor, seeing a favourable opportunity, entered into a correspondence with the Greek emperor, and surrendered to him the city; and, though Othmán immediately reinstated Amrú, who recovered Alexandria and demolished its fortifications, this was not accomplished without great difficulty and considerable bloodshed (A.D. 646). Saad Ibn Abí Wakkass and Abú Músa Al-ashari, two of Mohammed's companions, were also deprived by him of their command. Othmán rendered himself further obnoxious by occupying on the *Mimbar* (pulpit), and while at prayers in the mosque, the same place which the prophet had used, instead of placing himself, as his predecessors Omar and Abú Bekr had done, a few steps lower down. He had also lost from off his finger a silver signet ring which had once belonged to the prophet, and with which the khalifs his predecessors had sealed their despatches—

an ominous circumstance, which was regarded by all zealous Moslems as the greatest blow that could be inflicted on their rising empire—and he had recalled from his exile Hakem Ibn Aass, whom the prophet himself had banished from Mecca. Othmán was further accused of excessive prodigality towards his favourites. These and other complaints against Othmán increasing the public discontent, the elders of the Arabian tribes and the most illustrious among the companions of the prophet met at Medina, and having drawn up a memorial in which their charges, nineteen in number, were fully specified, they despatched with it one of their number, Ammar Ibn Iásir, threatening Othmán with immediate deposition unless he gave a satisfactory answer to every one of them. Othmán resented this as an outrage upon his authority, and caused Ammár, the bearer of the memorial, to be so severely beaten by his slaves, that he was left for dead on the ground. This unjustifiable act inflamed the passions of the people, who now openly demanded Othman's abdication. Deputations from all the provinces of the empire, having the same object in view, reached Medina, and Othmán was closely besieged in his palace by a large body of insurgents. In vain did Othmán promise to restore to the treasury the sums he had abstracted, to redress all grievances and answer all complaints; the fury of the people increased instead of abating, and they would undoubtedly have committed violence upon his person had not Ali, who had considerable influence among the insurgents, promised in the khalif's name that all causes of complaint should be immediately removed. The tranquillity, by these means restored, was but of short duration. Ayesha, the widow of the prophet, who hated Othmán, and who had seen with envy his accession to power, now openly favoured the pretensions of Talhah to the khalifate. By her authority among the Arabian tribes, as well as by her intrigues, she succeeded in creating great disaffection against Othmán, and attaching the most influential people in the empire to her interests. She bribed Othmán's secretary, Merwán Ibn Hakem, to transmit false orders in his master's name. One of these, addressed to Abdullah, governor of Egypt, bid him put to death Mohammed, son of the khalif Abú Bekr, who was then residing at Alexandria, and followed the party of Ayesha. No sooner was the khalif's order made known, than Othmán's enemies eagerly urged Mohammed to revenge the affront. He accordingly marched against Medina, which he entered without opposition, and invested Othmán's palace. After making some resistance, Othmán's soldiers left him to his fate. Placing a Korán in his bosom, the khalif calmly awaited the arrival of the assassins, who, headed by Mohammed, rushed into the room. The incensed youth seized Othmán by the beard, and plunged his sword into his breast; others pierced his body in different parts, and he expired under numerous wounds. For three days his mutilated corpse lay unburied and exposed to the insults of the populace, until it was at length thrown into a hole. This happened, according to At-tabári and Abú-l-fedá, on the 18th day of Dhi-l-hajjah, A.H. 35 (18th June, 656); other historians assign earlier dates to this deplorable event, although all agree in placing it within that month. Othmán reigned twelve years, and was eighty-two, others say ninety, and even ninety-five years old when he died. He had been married to two of the daughters of the prophet, Rakiyyah and Om-al-Kolthúm, owing to which he is generally designated by the Arabian historians under the surname of *Dhú-n-núreyn* (he of the two lights). Othmán is described as a man of majestic figure and venerable aspect; he was pious and well versed in the Korán, which he is reported to have transcribed several times. He was the first who caused an authentic copy of the Korán to be made, from which all others were to be transcribed. He entrusted the revision of it to Zeyd Ibn Thábit, Abdallah Ibn Zobeyr, and other companions of the prophet. Until the eleventh century of our æra, a copy of the Korán called *Mushafu-l Othmáni* (the volume of Othmán) was preserved in the great mosque at Cordova, being thought by some authors to contain four leaves of the Korán which Othmán placed in his bosom, and stained with his blood, and by others to be one of those copies which the khalif was known to have written himself.

(As-soyútí's *History of the Khalifs*, in MS., in the Brit. Mus., No. 7324; Abú-l-fedá, *An. Mosl.*, vol. i., p. 240, *et seq.*; Al-makin *apud* Erpenium, p. 31, *et seq.*; Abú-l-faraj, *Hist. Dynast.*, translated by Pococke, p. 57, *et seq.*; Ockley, *Hist. of the Saracens*, vol. i.; Price's (Major) *Retrospect of Mohammedan History*, vol. i.)

OTHMA'N I., surnamed Al-ghází (the Conqueror), the founder of the dynasty now reigning at Constantinople, was born at Súkút in Bithynia, in 657 of the Hejira (A.D. 1259). The Turkish and Arabian historians do not agree as to his ancestors and origin, but the most generally received opinion is, that he was the son of Orthogrul, a Turkman or Oguzian chieftain, who, having entered into the service of the sultán of Iconium, established himself with his tribe at Surgút, on the banks of the river Sangar. It is further related that his grandfather Suleymán left his native steppes in the Má-wará-l-nahr (beyond the Oxus), passed into Khorassán at the time of the invasion of Genghis Khan (A.D. 1218-19) [GENGHIS KHAN], and settled at Keláth in Armenia. After the death of Suleymán, who was drowned in the Euphrates, his son Orthogrul succeeded him in the command of the tribe. He marched farther into Asia Minor, and entered the service of Alao-d-din Caycobad, the ninth sultán of the Seljúkian dynasty, whose reign began in A.D. 1213. Having received lands to settle in with his tribe, Orthogrul rendered important services to Alao-d-din and his successors, aiding them in their wars against the Tartars and against the Greeks. Orthogrul died in A.H. 680 (A.D. 1280), leaving his son Othmán to succeed him in the government of the colony. After the death of Masúd II., the last of the Seljúkides, his dominions being shared among his generals, part of the province of Bithynia fell to the lot of Othmán, who thus found himself the master of a small territory. The first campaigns of this conqueror were directed against the Greeks. In July, A.D. 1299, having first forced the slightly-defended passes of Mount Olympus, he invaded the territory of Nicæa, and subdued the whole country, except the capital itself, which fell four years afterwards into his power (1304). In 1307 he invaded and reduced the country of Marmara. The annals of the first years of his reign exhibit the same repetition of successful inroads, until, seeing his army increased by captives and volunteers, he meditated and carried into execution greater undertakings. Instead of retreating as before, after each incursion, to the hills, he maintained the most useful and defensible posts, fortified the towns and castles, and strove to maintain every foot of ground which he gained from the enemy. In the course of many years of warfare he conquered the remainder of Bithynia and the neighbouring provinces; and although he was several times repulsed in his attempts upon Nicomedia and Prusa, he kept those cities in awe by means of strong fortresses which he erected in their neighbourhood. At length his son and successor, Orkhán, gained possession of Prusa, but the welcome news did not arrive till Othmán was almost insensible, owing to old age and infirmities. Othmán died in A.D. 1326, in the sixty-ninth year[*] of his age and the twenty-seventh of his reign, reckoning from his first invasion of Bithynia. He held his court at Cara-Hissar and coined money in his name, but he never took the title of sultan. Such was the commencement of the Turkish empire [TURKEY], which, from his name, has received the appellation of Othoman or Ottoman Porte. The memory of Othmán is held in such veneration by the Turks, that, on the accession of a new sultan to the throne of Constantinople, no greater compliment can be paid to him than to wish him as happy a reign, as long a life, and all the kindness of Othmán. He was famed for his moderation, his justice, his military talents, and his prudence: he left to his son Orkhán a book of maxims and rules for the government of an empire, which are much esteemed.

(Von Hammer's *Journey from Constantinople to Brussa and to the Olympus*, Pesth, 1818, and *Geschichte des Osmanischen Reichs*, Pesth, 1827; D'Ohsson, *Tableau de l'Empire Othoman*; Abú-l-fedá, *An. Mos.*, vol. v.; Deguignes, *Histoire des Huns.*)

OTHMAN, IBN YAHIA ALCAISI, was born of a noble family at Malaga in Andalucia. He is mentioned as a man of great and varied talents, and as having been eminent in philosophy, law, and medicine. He was made governor of Malaga, and died A.H. 735 (A.D. 1334). He was the author of a work containing many grammatical questions (*Quæsita Grammatica*); another, 'De Hæreditate,' and a third, 'De Mensuris Hispanis.' (Casiri, *Biblioth. Arabico-Hisp. Escur.*, t. ii., p. 109.)

---

[*] Sixty nine lunar or Mohammedan years make little more than sixty seven Christian years.

OTHO, MARCUS SALVIUS, was born on the 28th of April, A.D. 31 or 32. He was descended of an honourable family, which originally came from Ferentinum (*Ferentino*), and which traced its origin to the kings of Etruria. His grandfather, who belonged to the equestrian order, was made a senator through the influence of Livia Augusta, but did not rise higher in office than the praetorship. His father, Lucius Otho, was advanced to offices of great honour and trust by the emperor Tiberius, whom he is said to have resembled so closely in person as to have been frequently taken for a near relation.

Marcus Otho was an intimate friend of Nero during the early years of his reign, and his associate in his excesses and debaucheries; but Nero's love for Poppaea, whom Otho had seduced from her husband, and to whom he was greatly attached, produced a coolness between them, and ultimately occasioned the honourable banishment of Otho to the province of Lusitania, of which he was appointed governor. In this province, which he governed, according to Suetonius (*Otho*, c. 3), with great justice, he remained for ten years; and afterwards took an active part in opposition to Nero and in placing Galba upon the throne, A.D. 69. Otho appears to have expected, as the reward of his services, that he should have been declared his successor; but when Galba proceeded to adopt Piso Licinianus as his successor, Otho formed a conspiracy among the guards, who proclaimed him emperor, and put Galba to death after a reign of only seven months. [GALBA.]

Otho commenced his reign by ingratiating himself with the soldiery, whom Galba had unwisely neglected to conciliate. He yielded to the wishes of the people in putting to death Tigellinus, who had been the chief minister of Nero's pleasures, and he acquired considerable popularity by his wise and judicious administration. He was however scarcely seated upon the throne before he was called upon to oppose Vitellius, who had been proclaimed emperor by the legions in Germany a few days before the death of Galba. Vitellius, who was of an indolent disposition, sent forward Caecina, one of his generals, to secure the passes of the Alps, while he himself remained in his camp upon the Rhine. Otho quickly collected a large army and marched against Caecina, while he sent his fleet to reduce to obedience Liguria and Gallia Narbonensis (compare Tac., *Agr.*, 7.) At first Otho was completely successful. Liguria and Gallia Narbonensis submitted to his authority; while Caecina was repulsed with considerable loss in an attack upon Placentia. But shortly after, Otho's army was completely defeated by the troops of Vitellius in a hard-fought battle near Bedriacum, a village on the Po, south-west of Verona. Otho, who does not appear however to have been deficient in bravery, had been persuaded for the security of his person to retire before the battle to Brixellum; a step which tended, as Tacitus has observed, to occasion his defeat. When he was informed of the result of the battle, he refused to make any further effort for the empire, and put an end to his own life by falling upon his sword, at the age of 37, according to Tacitus (*Hist.*, ii. 50), or of 38, according to Suetonius (*Otho*, c. 11), after reigning 95 days. Plutarch relates that the soldiers immediately buried his body, that it might not be exposed to indignity by falling into the hands of his enemies, and erected a plain monument over his grave with the simple inscription, 'To the memory of Marcus Otho.'

(Tacitus, *Hist.*, books i. and ii.; *Life of Otho*, by Suetonius and Plutarch; Dion Cassius, lib. lxiv.)

Coin of Otho.
British Museum. Actual size. Copper.

OTHO I., son of the emperor Henry I., and duke of Saxony, was elected, after his father's death, A.D. 937, his successor on the throne of Germany. His reign was long and eventful; a great part of it was occupied in quelling the rebellions of the great feudatories, the dukes of Bavaria, Franconia, and Lorraine, the archbishop of Mainz, and of his own son and son-in-law, who had rebelled against him. He waged also a long and successful war against Boleslas, duke of Bohemia, who, having murdered his own father, had abolished Christianity and thrown off his allegiance to the empire. He conquered the Slavi of the region bordering on the Oder, and founded two bishoprics, Havelburg and Brandenburg, in order that they might furnish missionaries for the conversion of the Slavi to Christianity. Otho defeated also the Danes, for whose conversion he founded bishoprics in Holstein and Schleswig. In the year 955 he gained a great victory over the Huns. In Italy he appeared first as the champion of Adelaide, the young widow of king Lotharius, who had been imprisoned and otherwise ill-used by Berengarius, who, after poisoning Lotharius, had usurped the Italian crown. Otho liberated Adelaide, whom he married at Pavia, in the year 951, and forgave Berengarius, and allowed him to retain the sovereignty of Italy, but as his vassal. Otho then returned to Germany. After seven years, fresh complaints of the tyranny of Berengarius induced Otho to recross the Alps: he defeated Berengarius and his son and colleague Adalbert. He was himself acknowledged by a Diet held at Milan as king of Italy, and crowned by the archbishop with the iron crown of the Longobards in the church of St. Ambrose, at the close of A.D. 961. In the following year Otho repaired to Rome, where pope John XII. crowned him emperor of the West, as being the successor of Charlemagne. Berengarius, who had still some followers, defended himself obstinately in the fortress of St. Leo, in the Romagna; but being taken, was sent prisoner to Bamberg, where he died.

Meantime Otho, having received numerous complaints against pope John, whose licentiousness and tyranny had become insupportable to the people of Rome, and who moreover maintained secret intelligence with the partisans of Berengarius, again visited Rome, and assembled a council, in which John was deposed, and Leo VIII. elected in his place. John however, after Otho's departure, re-entered Rome, obliged Leo to run away, and committed many acts of cruelty against those who had favoured the exaltation of his rival. [JOHN XII.] John soon after died, A.D. 964, and the Roman clergy, disregarding the former election of Leo, appointed another pope by the name of Benedict V. This brought Otho again to Rome, which he besieged and took. He banished Benedict and reinstated Leo, who however died the year after, when John XIII. was elected with Otho's approbation. But the Romans, revolting against the new pope, banished him into Campania. Upon this Otho again entered Rome, and having put the leaders of the insurrection upon their trial, hanged thirteen of them, and condemned the others to various punishments. The historian Liutprandus justifies the conduct of Otho on this occasion, saying that he merely exercised his imperial prerogative, like his predecessors of the Byzantine and Carlovingian dynasties, against men who had violated their oaths and rebelled against his authority. This shows that at that time the duchy of Rome was still considered as subject to the emperors.

In the year 967 Otho had his son Otho II. crowned emperor and his colleague, at Rome, by pope John XIII. In the following year Otho sent Liutprandus on a mission to Nicephorus Phocas, emperor of Constantinople, which however produced no friendly result. [LIUTPRANDUS.] Otho accordingly invaded the provinces of Campania, Apulia, and Calabria, which were subject to the Byzantines, and laid siege to Bari, which however he did not take. Nicephorus in the meantime being murdered, his successor Zimisces made peace with Otho, and gave the princess Theophania in marriage to his son, A.D. 972. Otho returned to Germany, where he died in May, 973. Otho has been styled 'the Great,' a title which he deserved for his abilities, his success, and his love of justice. His policy towards the see of Rome is worthy of notice, for whilst he showed himself zealous for the interests of the church, endowed abbeys and convents, and honoured deserving men among the clergy, yet he always asserted his sovereign right in temporal matters, and in the elections of the popes, a right which his successors continued to exercise for a long time afterwards until the pontificate of Gregory VII. In Italy he established the supremacy of the German emperors over the greater part of the peninsula, with the exception of the southern provinces, which remained subject to the Eastern empire.

OTHO II., son of Otho I., was engaged after his father's death in a war with Henry, duke of Bavaria, whom he defeated, and whose fief he bestowed on the duke of Suabia. He had also to contend against Lotharius, king of France, for the possession of the great fief of Lotharingia, or Lorraine, which had been a subject of contention between France and Germany ever since the separation of the two crowns. Otho divided Lorraine into two fiefs, upper and lower, the latter of which he left to Charles, Lotharius's brother, on condition that he should pay allegiance to the German crown. In the year 979 Otho repaired to Italy, where things were, as usual, in a state of great confusion. At Rome he repressed sedition, and punished several of the leaders. From Rome he proceeded into Campania, and interfered in the interminable quarrels of the various princes of Capua, Benevento, and Salerno; and from thence advanced into Apulia and Calabria, where he fought against the Saracens, who had landed in those provinces, and who were encouraged, as it was said, by the Byzantine emperor, who was afraid of losing his Italian dominions through Otho's ambition. Otho occupied Tarentum, and at first was successful against the Saracens; but he afterwards was defeated by them with great slaughter. (Sigonius; Ditmar; Muratori.) Otho, returning to Northern Italy, assembled a general diet of the feudatories of Germany and Italy at Verona, in the year 983, at which his son, then four years old, afterwards Otho III., was acknowledged as his successor. At that diet several laws were added to the Longobard code, and Otho confirmed the franchises and privileges of the republic of Venice by a diploma, in which are enumerated the provinces that were subject to the kingdom of Italy as distinct from those belonging to Venice. The former are Pavia, Milan, Cremona, Vicenza, Ceneda, Verona, Friuli, Istria, Ferrara, Ravenna, Comacchio, Rimini, Pesaro, Cesena, Fano, Sinigaglia, Ancona, Umana, Fermo, Pinna, and Gabella, a statement which contradicts the pretended grant of the Exarchate and Pentapolis, said to have been made by Otho I. to the see of Rome. From Verona, Otho proceeded to Ravenna, and afterwards to Capua and Benevento, intent upon collecting a large army against the Saracens, whom he wished to expel from Sicily. But in the month of December, 983, he fell ill at Rome, where he died, and was buried in the atrium of the Vatican Basilica.

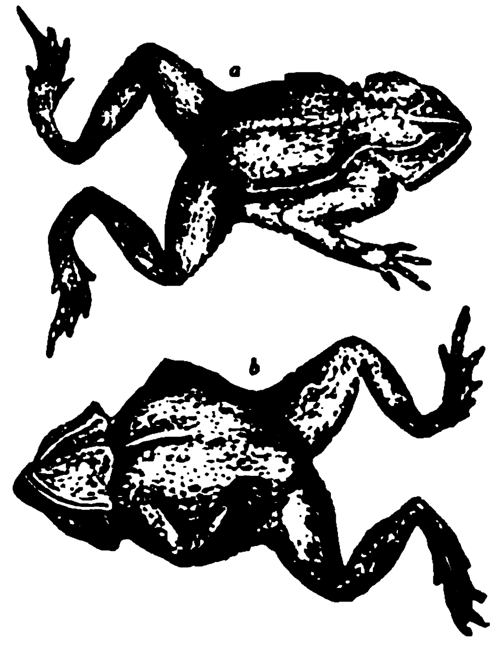
OTHO III. spent his long minority in Germany, whilst his grandmother Adelaide, his mother Theophania, and the archbishop of Cologne administered his dominions in Germany and Italy. In the year 996 Otho entered Italy with a large army, and was crowned emperor of Germany, at Rome, by Pope Gregory V., who was his own relative. On his return to Germany, he defeated the Slavi, with whom he was engaged in a war, and forced Micislas, duke of Poland, to do him homage. He afterwards conferred upon his successor, Duke Boleslas, the title of king of Poland. At the end of 997, Otho returned to Italy; and after staying awhile at Pavia and Ravenna, being desirous of seeing Venice, a city then already celebrated for its wealth and power, he repaired thither incognito with six attendants. The doge Pietro Orseolo II. entertained him splendidly by night, but left him to enjoy his assumed disguise during the day. The doge had just effected the conquest of Dalmatia from the Croatians, with the islands of Curzola and Lesina, and had assumed the title of duke of Dalmatia. Otho held a daughter of the doge's over the baptismal font, and on that occasion he exempted the Venetians from the pallium, or annual tribute, which they used to pay to the kings of Italy. Having returned to Ravenna, he collected his army and marched upon Rome, from whence Pope Gregory V. had been expelled by the patrician Crescentius, styled consul of Rome; a remarkable character of the dark ages, who aspired to re-establish the Roman republic under a nominal allegiance to the Eastern emperors. Crescentius caused John, a Calabrian Greek, to be proclaimed pontiff, under the title of John XVII. On the arrival of Otho, John ran away; but being seized by those of the adverse party, he was cruelly mutilated; and Crescentius, after defending himself in the castle St. Angelo, was also made prisoner and beheaded, with twelve of his followers. Otho returned to Germany, but in the year 1001 he was again in Italy. He fought several battles in Campania, besieged Benevento, and afterwards quelled some fresh disturbance in Rome. In the following year, 1002, he was taken ill near Civita Castellana and died. His body was taken to Aquisgrana to be buried.

OTHO IV., duke of Brunswick and son of Henry the Lion, was elected king of the Germans in 1208, and was afterwards crowned emperor at Rome by Innocent III. But he soon quarrelled with that imperious pontiff about the right of nominating to vacant benefices. Otho returned to Germany, where Waldemar, king of Denmark, was extending his conquests along the southern coast of the Baltic. Soon after a general discontent, which was encouraged by the clergy, burst out against him, and he was deposed in 1212; and Frederic of Hohenstauffen, king of Sicily, was called to fill the throne of his ancestors. Otho however had still a considerable party, and he protracted the contest till 1215, when he resigned his claims to his rival. [FREDERIC II., EMPEROR.]

OTHO, or OTTO, OF FREYSINGEN, born about 1108, was the son of Leopold, margrave of Austria, and of Agnes, daughter of the emperor Henry IV. He studied first at Nürnberg and afterwards in the university of Paris, after which he entered the order of St. Bernard in the abbey of Morimond, of which, in 1136, he was made abbot. His relative Conrad III., king of the Germans, recalled him to his native country and made him bishop of Freysingen in 1138. He afterwards followed Conrad in the crusade to Palestine. On his return, he felt a wish to visit the abbey of Morimond again, where he died, after a short illness, in 1158, much revered for his knowledge and piety. He wrote a chronicle of the world in 7 books, 'Ottonis Episcopi Frisingensis Rerum ab origine Mundi ad ipsius usque Tempora,' fol., Augsburg, 1515. The first four books of this Chronicle are a mere compilation from Orosius, Eusebius, Isidore of Seville, and other previous writers; but the last three books contain much original information, especially concerning the affairs of Germany in the 10th, 11th, and 12th centuries. Otho is a remarkably impartial historian, and sufficiently judicious for the times in which he lived. His Chronicle was continued down to the year 1210 by another Otho: 'Appendix Ottonis à S. Blasio à fine libri septimi Ottonis usque ad annum Salutis,' 1210. The other works of Otho of Freysingen are—1, A treatise concerning the end of the world, according to the Book of Revelations, which is generally appended to his Chronicle; and 2, A history of the emperor Frederic I., called Barbarossa, 'De Gestis Frederici Ænobarbi libri duo,' which comes down to the year 1159, but has been continued by Radewik, canon of Freysingen, down to 1160. Otho is one of the most trustworthy historians of the period generally called the dark ages.

(Vossius, *De Historicis Latinis*; Fabricius, *Bibliotheca Latina mediæ ætatis*.)

OTILOPHES (*Otilophi*), Cuvier's name for a group of *Batrachians* [FROGS, vol. x., p. 491], which have the muzzle



Rana margaritifera.

a, seen from above; b, placed on its back to show the under parts, granules, and the head furnished on each side with a crest which extends over the parotid portion.

Type, *Rana margaritifera*, Gmel.

Description.—*Head* triangular, approaching to square above, and with elevated borders, presenting an appearance somewhat resembling the episcopal mitre; *eyes* of a fine colour; *body* above red-brown, speckled with lighter red granules dispersed throughout like small pearls; a white stripe from the nose to the end of the rump; thighs and feet marbled with light yellowish; a small white line springing from the nose runs down on each side of the head and along the sides of the belly, which is whitish and granulated also like the back and upper parts.

Locality.—Brazil, where, according to Seba, it is called *Jaquaru*.

OTION. [Cirripeda, vol. vii., p. 207.]

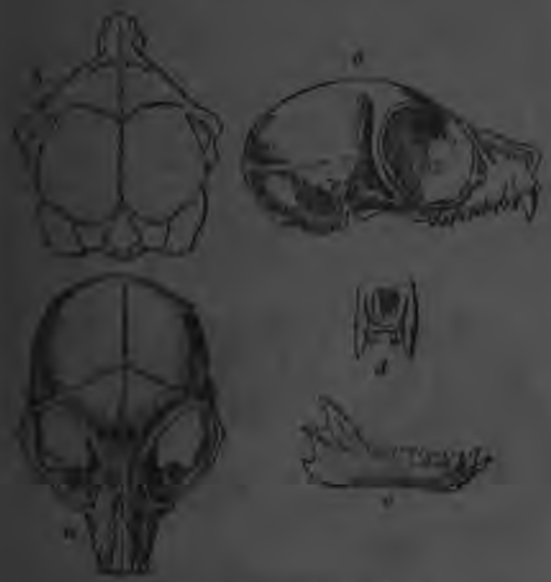
OTIS. [Bustard.]

OTOLICNUS, Illiger's name for the *Galago* of Geoffroy. Dental formula, this is generally given by authors thus:—

Incisors, $\frac{2}{6}$ or $\frac{4}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{6-6}{5-5}$.

In the species which we select to illustrate the form, Dr. Andrew Smith found the dentition as follows:—

Incisors, $\frac{4}{6}$; canines $\frac{1-1}{1-1}$; false molars, $\frac{2-2}{2-2}$; true molars $\frac{4-4}{3-3}$ = 18 in each jaw.



Skull and teeth of Galago Moholi. (Smith.)

a, Front view of skull; *b*, back view of same; *c*, lateral view; *d*, front view of the anterior portion of upper jaw; *e*, lateral view of lower jaw. All the figures nat. size. (Smith.)

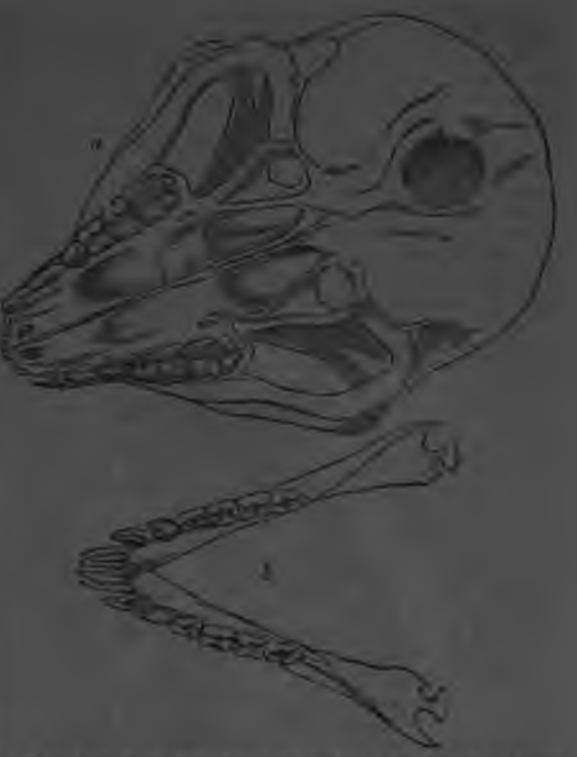
Generic Character.—Head rounded, muzzle short; eyes very large; ears very large. Feet pentadactyle; all the nails flat with the exception of the first digit of the hind feet, which is armed with a sharp subulate claw. Two teats. Tail very long, terete, and villous.

Geographical Distribution of the Genus.—Africa, to which Mr. Swainson adds India.

Habits.—Arboreal. The great size of the orbits will at once strike every observer. The large development of the eyes requires such spacious receptacles; and this development is necessary on account of the nocturnal habits of the genus. The food of these animals consists of soft fruits, and, from the structure of the teeth, probably of insects also. They are fond of vegetable gum, and their large ears are said to be closed when they sleep, but to be opened upon their hearing the least noise.

We select as an example the *Galago Moholi* of Dr. Smith.

Description.—*Colour*: Upper parts of the head and neck, the back, the sides of the body, and the outer and hinder surfaces of the extremities intermediate between pearl and yellowish grey; the back is finely brindled from the dark colour of the basal portion of the fur being here and there seen through the surface tints; the extremities are of a lighter hue than the other parts enumerated, and their outer and hinder surfaces are distinctly tinted with yellow; the middle of the face, the lips, the sides of the head, below and behind the eyes, the chin, throat, abdomen, and the upper surface of the fingers white; inner surfaces of extremities white, tinged with yellow. Tail glossy; the colour intermediate between yellowish-brown and cochineal red; the fur is throughout of the same colour; that of the other parts is a dark slate-colour except at and near its surface. Ears flesh-coloured; and the down, which is very sparingly scattered over their outer surface, is pure white. Eyes deep topaz yellow; the palms of the hands and under surface of the fingers are of a flesh-colour tinged with brown. *Form, &c.*—Figure slender and elegant. Head broad, subglobular, and anteriorly terminated by a short, high, and almost pointed nose. Ears large, bare, and patulous, their tips rather narrow and slightly rounded; the outer margin of each ear has two faint emarginations, and the internal or anterior surface of each is distinctly marked with four or more transverse ridges; the eyeballs and the pupils large; anterior extremities short and slender; posterior ones long, rather robust, and each is terminated by four fingers and an opposable thumb, the tips of which are dilated and depressed; the nail of the forefinger of each of the hinder extremities is narrow, convex, considerably elongated beyond the soft parts, and obtusely pointed; all the other nails both of the anterior and posterior extremities small, thin, flat, roundish or ovate in form, and not extended to the points of the fingers. Tail cylindrical, slender towards the base, much thicker towards and at the tip, which arises from the fur being longer on those parts. On the head, body, and extremities the covering consists of a very fine short woolly fur, which on the tail and the upper surface of the fingers is rather harsher. Palm of the hands and under surface of the fingers naked. (Smith.) Length from nose to tip of the tail, sixteen inches.

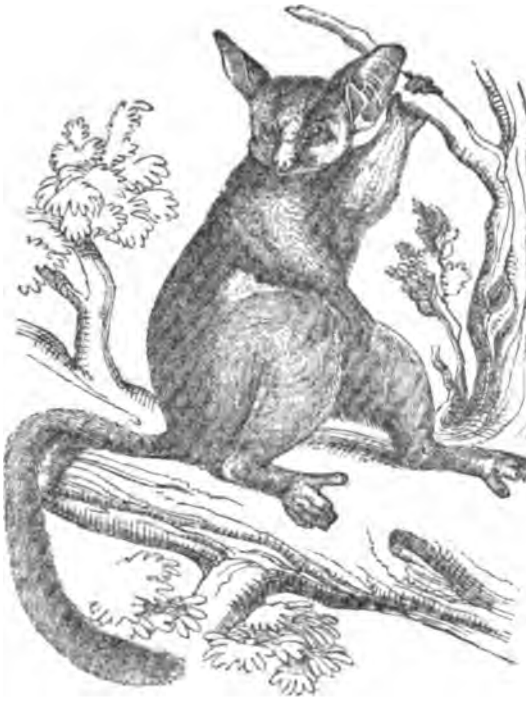


a, Basal view of skull, exhibiting the teeth; *b*, lower jaw. Both figures double the nat. size. (Smith.)

Locality, Southern Africa, and probably Western Africa.

Habits, Reproduction, Food, &c.—The first specimens observed by Dr. Smith were upon trees close to the Limpopo river, in about lat. 25° south, and from that parallel he continued to observe others as the expedition travelled. They were very active, springing from branch to branch and tree to tree with extraordinary facility, and always seized the branch on which they intended to rest. In their manners they considerably resembled the monkeys, particularly in grimaces and gesticulations. According to the natives, the species is entirely nocturnal, and rarely to be seen during the day, which the animal spends in the nest which it has formed in the forks of branches or in cavities of decayed trees; and in these nests, constructed of soft grass, the females bring forth and rear their young (generally two at a birth). Dr. Smith states that the food of the Moholi consists principally of pulpy fruits, though there is reason to believe it also consumes insects, as remains of the latter were discovered in the stomachs of several individuals which he examined.

Dr. Smith, for the reasons stated in his work, considers this animal different from *Galago Senegalensis*. He gives an elaborate anatomical description and good figures of the more important and interesting parts of this animal.



The Moholi.

Our figures are taken from those in the 'Illustrations of the Zoology of South Africa,' a work now in the course of publication under the authority of the Lords Commissioners of Her Majesty's Treasury, and equally valuable both for the extent and novelty of its information and the beauty and accuracy of the illustrations.

Place in the System.—Illiger places *Otolicnus* in the fourth family (*Macrotarsi*) of his second order (*Pollicata*), associated with *Tarsius*. The *Macrotarsi* stand in his arrangement between the *Prosimii* and the *Leptodactyla*.

Cuvier, placing the genus between *Stenops*, Ill., and *Tarsius*, arranges it under the *Quadrumana*.

Mr. Gray, in his 'Outline' (*Ann. Phil.*, 1825), makes *Otolicnus*, *Galago*, and *Cheirogallus** the genera which form his *Galagonina*, the fourth subfamily of his *Lemuridæ*.

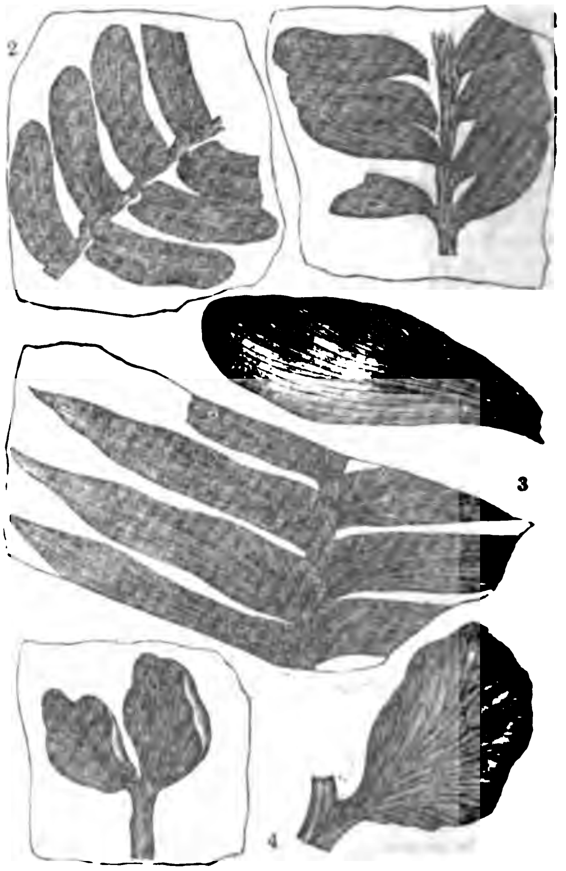
M. Lesson (1827) gives *Galago*—he does not notice Illiger's name—a position between *Nycticebus* and *Tarsius*; and J. B. Fischer (1829) places *Galago*, Geoff. (*Otolicnus*, Ill.) between *Jacchus* and *Tarsius*.

Cuvier (*Règne Animal*) expressed his opinion that the *Lemur Potto* of Gmelin should be referred to this group; and M. Lesson places that animal under *Galago*, with the name of Galago Potto, *Galago Guineensis*, Desm.

Mr. Swainson, who considers that nearly all the Lemurs appear to be referrible to two primary groups, the Lemurs proper (*Lemur*) and the Galagos (*Otolicnus*, Ill.), views the first group as eminently frugivorous, and the second as carnivorous, preying upon small birds, insects, and reptiles, and representing the *Feræ*. This latter group, *Otolicnus*, is, he observes, in general distinguished by the size of their hinder feet, or rather of the tarsus and toes, in which respect he thinks they offer a beautiful analogy to *Mænura*, *Rallus*, and *Crateropus* among birds. He traces the passage between the Lemurs and the Galagos in the genus *Stenops* of Illiger, where the tail, as in *Lichanotus*, is either very short or entirely wanting; and considers the remarks of Mr. Bennett (*Gardens and Menagerie of the Zoological Society*, vol. i.) on the impropriety of separating the slow-paced Lemur (*Stenops tardigradus*) from the slender Lemur (*Stenops gracilis*) to be well founded, observing that both belong in fact to the scansorial type, and that the latter is absolutely necessary to connect the former with the genus *Tarsius*. Mr. Swainson further states that much uncertainty hangs over an animal loosely described by Bosman under the name of *Potto* (*Lemur Potto*, Gm., *Nycticebus Potto*, Geoff.), which seems to have the form and the slowness of motion seen in the *Stenops tardigradus*, but yet to possess a long tail. 'Whether,' adds Mr. Swainson, 'such an animal exists or not, certain it is that no other could present a more natural link of connection between *Stenops* and *Otolicnus*. In this latter form, the tail is again remarkably developed; but, although tufted, it does not present that bushy and ornamented character which so much distinguishes the genuine Lemurs. It is not improbable that these Galagos, which have only two upper cutting teeth, as the *O. Demidoffii* and *Senegalensis*, belong to a different type from the others, where the upper cutting teeth are four in number; certain however it is that the *Tarsius Bancanus*, Horsf., or Great-headed Gorlago, is a genuine type of nature.' This last form has been elevated by Mr. Swainson to the rank of a genus under the name of *Cephalopachus*, and *Otolicnus* in his arrangement stands between *Stenops* and that genus in the family *Lemuridæ*. (*Classification of Quadrupeds*, 1335.)

O'TOMYS. [MURIDÆ, vol. xv., p. 103.]

OTO'PTERIS is a genus of fossil ferns, of which several species have been described. Its distinguishing character is to have simply pinnated leaves, whose leaflets are auricled at the base, where they join the rachis by a narrow stalk, and are furnished with veins which proceed directly from the base to the apex, without any attempt at forming a midrib. Five certain species only are known, from the beds above the coal-measures, and chiefly from the lias and oolitic formations, of which they are a characteristic feature: these are *O. cuneata*, *Beanii*, and *acuminata*, from the oolite, *obtusa* from the lias, and *Dufresnoii* from the new red-



1, Otopteris dubia; 2, Otopteris obtusa; 3, Otopteris acuminata; 4, Otopteris cuneata.

---

* 'Cheirogaleus' must be meant.

[illegible]. There is moreover an *O. dubia* from the [illegible] coalfield, and an *O. ovalis* from the Scarborough oolite beds, of which are doubtful species; the latter in particular must be excluded from the genus, and probably belongs to Neuropteris. A detailed account of the species will be found in the *Fossil Flora*, vols. ii. and iii., where the genus was first established, and where are figures from which the annexed cuts have been borrowed.

It is probable that the genus is the same as either the modern Adiantum, or Lindsæa, with both which it agrees in the venation of the leaves.

OTRANTO, TERRA DI, one of the territorial divisions of the kingdom of Naples, is also called 'Provincia di Lecce,' from the name of its present head town. It occupies the whole Iapygian or Messapian peninsula, being bounded by the province of Bari on the north-west, by that of Basilicata on the south-west, and by the sea on every other side. Its greatest length is about 100 miles, from north-west to south-east, and its greatest breadth is about 30 miles, but it becomes much narrower as it approaches the promontory of Leuca. The peninsula is traversed in its length by a ridge of low calcareous hills, which are an offset of the mountains of Basilicata, and run to the cape of Leuca. There are no rivers properly so called in this peninsula, but the springs and drainings of the hills on both sides form streams, most of which are absorbed by the soil or lose themselves in marshes before they reach the sea. Nearly the whole of the low tract of land along the sea-coast on both sides of the peninsula is unwholesome and thinly inhabited, with the exception of the towns of Brindisi, Otranto, Taranto, and Gallipoli; but the interior, being more elevated and dry, is wholesome, and produces oil in abundance, wine, corn, and pasture for cattle. The oil is chiefly exported from the port of Gallipoli.

The population of the province, which in 1827 amounted to 3[illegible],000, was, in 1837, 365,294. This population is distributed among four districts: Lecce, Taranto, Brindisi and Gallipoli, which are subdivided into 122 communes and 1[illegible] parishes. More than two-thirds of the population live by agriculture. There are about 200 vessels (chiefly small craft) and boats belonging to the province. The manufactures are of no great importance. (Petroni, *Censimento de' reali Dominj di qua del Faro*; Serristori, *Statistica d'Italia*.)

The principal towns of the province of Otranto are:—1, Brindisi; 2, Lecce; 3, Taranto; 4, Gallipoli. Gallipoli is a town of considerable commercial importance, built on a rocky peninsula. It contains, together with the suburb called Lizza, about 12,000 inhabitants, is a bishop's see, has a good roadstead, and a harbour lately constructed by means of a mole. It is the most trading seaport on the Ionian side of the kingdom. It has ample cisterns cut in the rock for containing the oil, which is the chief produce of the country. Gallipoli exports oil, wool, wine, and other produce of neighbouring provinces. The tunny fishery employs also many persons. 5, *Otranto*, the antient Hydruntum, once a flourishing town, has been in a decaying state since its capture and pillage by the Turks in 1480. Its present population hardly exceeds 3000, and the surrounding country is marshy, unhealthy, and uncultivated. Otranto has an old cathedral, a castle, and a harbour which is not very safe. From Otranto, on a clear day, the opposite coast of Epirus and the lofty Acroceraunian Mountains can be seen. (Keppel Craven, *Tour through the Southern Provinces of the Kingdom of Naples*.)

The following towns are also in the province of Otranto: Alessano, near Capo Leuca, with about 7000 inhabitants; Castellaneta, with 5000; Nardò, with 8000; Francavilla, with 12,000; and Manduria, with 8000, and a remarkable well in the neighbourhood, mentioned by Pliny (*Hist. Nat.*, ii. 106), the water of which always retains the same level, whatever quantity is drawn from it. Some Greek or Epirote colonies are scattered about the province: the principal villages inhabited by them are S. Marzano, Martano, and [illegible]. They still speak a corrupt Greek, and retain something of their national dress. Many of the 'masserie,' or farm-houses, in this part of the country are built like forts, and occupy a considerable extent of ground, in which the country-people, in the case of a landing being made by the Turkish corsairs, to which they were exposed for some centuries, or of incursions of inland banditti, could take refuge with their cattle and movable effects. A wall, high and strongly built, forms a parallelogram, against one side of which the dwelling-house is built, containing two or three habitable rooms and sometimes a chapel; the granaries, stables, and outhouses are on the other side, and in the middle of the enclosure is a round or square tower two stories high, standing quite alone. The ascent to the first story is either by some steps inserted in the tower or by a moveable ladder.

This remote province was, in the year 1816, after the restoration of King Ferdinand, the scene of a singular warfare between the royal troops and a considerable body of partisans belonging to the secret political associations of that period, who called themselves 'European Patriots,' 'Decisi,' 'Carbonari,' &c. The armed partisans were led by a priest named Ciro Annichiarico, who had been formerly in the prison of Lecce for committing several murders, but had contrived to escape. These outlaws assumed the name of the 'Salentine Republic,' and issued proclamations threatening with death those who should refuse them assistance. They had a black standard with the cap of liberty on a skull between two axes, and other symbols of a like character. After they had committed many excesses and kept the country in a state of anarchy for nearly two years, King Ferdinand sent against them General Church, with a body of 1200 soldiers and full powers. After some fighting, Ciro Annichiarico was surrounded and taken in the masseria of Scasserba, ten miles from Francavilla. He was tried before a court-martial, condemned, and executed in February, 1818, with above 100 followers. A curious account of the whole business is given in the 'Memoirs of the Secret Societies of the South of Italy,' London, 1821, translated from the French MS., which was said to have been written by Bartholdy, who was at one time Prussian diplomatic agent at Rome and Naples.

The peninsula of Otranto was antiently called by various names: Iapygia, Messapia, Calabria, and the country of the Salentini. The antient Iapygians or Messapians were probably native tribes of the great Oscan family [Apulia]; they were looked upon as barbarians by the Greeks, who had formed settlements upon their coasts. Thucydides (vii. 57), in the muster of the Athenian forces before Syracuse, names the Iapygians as auxiliary barbarians. They were often at war with the Greeks of Tarentum, whom they defeated with great loss about the year of Rome 281 (Herodotus, vii. 170; and Diodorus, xi. 52); but they were afterwards repeatedly defeated by Archytas. The name of Iapygia was given by the Greeks to the whole of Apulia as far north as Mount Garganus. The Romans divided the same antient tract between Apulia and Calabria. The coins found at Acerenza, Oria, and other places in this region bear Oscan characters. Horace calls the people of Canusium 'bilingues,' because they spoke Greek besides their native tongue; and the vulgar language of Rudiæ, the birth-place of the poet Ennius, was likewise a dialect of the Oscan. (Gellius, xvii. 17.) Further particulars concerning the antient history of this country are given under Taranto.

OTTAJA'NO. [Naples, Province of.]

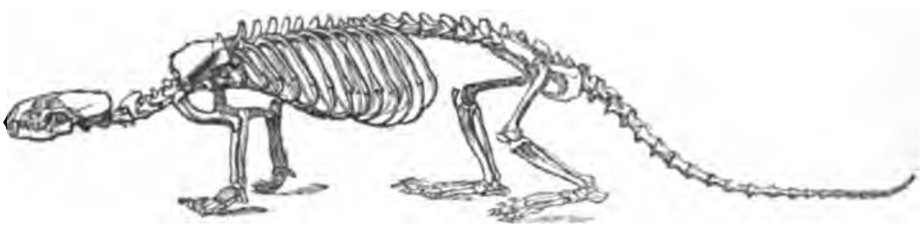
OTTAWA. [Canada.]

OTTER. The Otters (*Lutra*, Linn.) form a natural group of carnivorous animals whose habits are aquatic and whose food is fish. They consist of two forms nearly allied: the first, including the *River Otters*, *Lutra* of Storr; the second, the *Sea Otter*, *Enhydra* of Fleming.

ORGANIZATION.

Skeleton; Skull.—In the Otters the suborbital hole is larger than it is in the badgers, the gluttons, and the martens, almost as large, indeed, as it is in the rodents; their muzzle is shorter and the anterior part of the cranium between and behind the orbits more compact; their tympanic cavities are less convex; their entire cranium more depressed, and its base wider and flatter. The lachrymal bone is entirely within the orbit, and its aperture is above the interior suborbital hole. The circular aperture is blended externally with the spheno-orbital hole, but internally it is separated by a considerable interval from it by a bony plate. The internal pterygoid process is widened. The whole skull has a good deal in common with that of the seal (*Phoca vitulina*); and its relationship is to be traced in the short muzzle, the compression of the interorbital region (which is carried still farther in the seal), the width and flatness of the cranium, and the flatness and enlargement of the whole inferior region, with the exception of the tympanic cavities, which in the seal are large and convex.

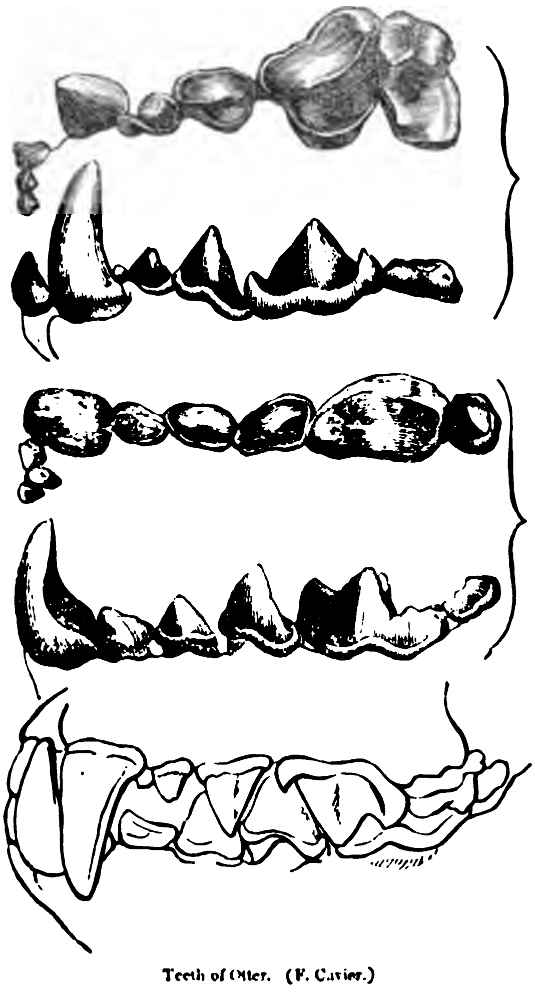
In the other parts of the skeleton there is nothing to justify a detailed description, the variations being such as might be expected to suit the habits of an aquatic, carnivorous, hairy quadruped. Thus, the articulation of the limbs admits of such freedom of motion, that the animal can turn them in almost any direction, and bring them with ease on a line with the body, so as to act like fins



Skeleton of European River Otter, Lutra vulgaris.

Digestive Organs.—The teeth of the Otters are sharp and strong, and the tubercles of the molars very pointed, a modification necessary to secure the prehension and speedy destruction of their agile and slippery prey. In the length of the intestines there is a difference between the *Common Otter* and the *Sea Otter;* the latter, like the *Seal*, has very long intestines. Sir Everard Home gives the length of the intestines of the Sea Otter as twelve times that of the animal; but those of the Common Otter as only three times and a quarter the length of the animal. (*Phil. Trans.*) Professor Owen however informs us that in a female common otter dissected by him, the intestines were 9 feet 6 inches, the body from nose to vent being 1 foot 5 inches; and we should expect, physiologically, to find longer intestines in a common otter than in one of the land *Feræ*.

Urinary and Genital Organs.—The kidney is lobulated or conglomerated, consisting, in fact, of an aggregation of small kidneys, connected by cellular substance; but these small kidneys are not so numerous as in the seal and porpoise. (Home on the 'Sea Otter,' *Phil. Trans.*) In the Museum of the Royal College of Surgeons (Physiological Series, No. 2519) is a preparation exhibiting the testes penis, anus, and anal glands of the Common Otter.



Teeth of Otter. (F. Cuvier.)

Nervous System and Senses.—Taste, smell, and hearing appear to be well developed. Sight remarkably quick. Touch moderate, except about the muzzle, lips, and whiskers, where it appears to be acute.

Generic Character. [LUTRA.]—*Head* compressed; *eyes* rather large; *ears* very short; *whiskers* very stiff; *tongue* rather rough; *body* very much lengthened; *legs* short; the *feet* with five toes and webbed; *tail* long, stout, flattened horizontally, and covered with short hair.

Dental Formula:—Incisors $\frac{6}{6}$; canines $\frac{1-1}{1-1}$; molars $\frac{5-5}{5-5} = 36$.

EUROPEAN LUTRÆ.

Example.—*Lutra vulgaris*, Erxleb. *Mustela Lutra*, Linn.

Description.—Head and nose broad and flat, neck thick, body elongated. Tail broad at the base, compressed horizontally, and tapering to a point.

The eyes, which are not large, are placed comparatively near to the nose; the ears are very short and the auditory opening rather narrow. The mouth is small and the lips are capable of being firmly closed together. The whiskers are very long, the legs very short, strong, stout, and muscular. The five-toed feet are furnished with strong broad webs, like those of water-fowl which have these accessories best developed. Hence Somerville terms the Otter 'goose-footed.'

Colour.—Brown (deepest on the upper parts), with the exception of two small patches of white on the lips, one on each side of the nose.

Size.—This species varies much in size. The length of one sent to Mr. Bell from Sutherlandshire was two feet one inch and six lines. Mr. Macgillivray notes the length of two males; one measured 42 inches, and the other 35 inches. By the same author, the length of a female is given at 40 inches. These measurements are from the nose to the point of the tail. Mr. Bell states that the usual weight of a fine male English Otter is from 20 to 24 pounds, and that of the female about 4 pounds less; adding however that Pennant records one found, in 1794, in the river Lea between Stratford and Ware that weighed 40 pounds.

This, there can be little doubt, is the ἐνυδρίς (Enhydris) of Aristole and the Greeks, and the *Lutra* of the antient Italians. It is the *Lodra*, *Lodria*, and *Lontra* of the modern Italians; *Nutria* and *Lutra* of the Spanish; *Loutre* of the French; *Otter* and *Fisch Otter* of the Germans; *Otter* of the Dutch; *Utter* of the Swedes; *Odder* of the Danes; *Dyfrgi* of the Welsh; *Balgair*, *Cu-donn* (Brown Dog), and *Matadh* of the Northern Celts; and *Otter* of the modern British.

Habits, Food, Reproduction, &c.—The natural food of the Common Otter is fish, for the chace and capture of which its whole frame is beautifully adapted. How silently is the water entered! The eyes are so placed that whether the animal is swimming below its prey, behind it, above it, or beside it, their situation, or, at most, the least motion of the head and neck, brings it within the sphere of the pursuer's vision. The whole frame-work of the animal, its short fin-like legs, oary feet, and rudder of a tail, enable it to make the swiftest turns, nay, almost bounds in the water, according as the rapidity of its agile prey prevents a sudden downward dive, an upward spring, or a side snap. The short fur, which is close and fine, keeps the body at a proper temperature, and the longer and outer hairs directed backwards enable it to glide through the water, when propelled horizontally by its webbed feet beneath the surface, noiselessly and speedily. Easy and elegant in its motions there are few objects more attractive in menageries than the pond, especially if it be kept clean and supplied with clear water, wherein the Otter is seen to hunt its living prey. When it has seized a small fish, it usually leaves the water and devours it, beginning with the head, whilst the body is held between the fore-paws. Larger fish are held down by the paws, and the head and tail are often left uneaten. The havoc made by these animals in the rivers and ponds is great; for they will go on killing, and eat but a small portion of each fish, if it be large, when they find plenty of prey. When fish is scarce and it is pressed by hunger Mr. Bell states that the Otter has been known to resort far inland, to the neighbourhood of the farm-yard, and attack lambs, sucking-pigs, and poultry. Mr. Macgillivray tells us, also, that it has been known to devour young domestic animals, and the latter zoologist found the stomach of one, which was killed in June, filled with a curious collection of larvæ and earth-worms. The period of gestation is said to be nine weeks, and the number of young produced varies from three to five. The Otter's places of refuge near rivers and lakes are beneath the roots of trees or in holes.

But it must not be supposed that the *Common Otter* is, as it has been asserted, confined to the fresh-waters. They are known to frequent the sea in the north of Scotland and to hunt for [illegible]. In the south of England (Cornwall) the Otter will go a mile from the shore in the summer and good weather after its prey, according to Mr. Couch. On the sea-shore, rocky caves with scattered blocks, hollows, and cavities under large stones, are its haunts. These marine common otters must not be confounded with the *Sea Otter* (*Enhydra*).

That the Common Otter is capable of domestication and attachment we have ample testimony. Albertus Magnus, Aldrovandus, Gesner, and others attest this. Every angler will remember the passage in Walton, where good Mr. Piscator is anxious to possess himself of one of the young otters which the huntsman, after the death of the 'bitch otter,' had found. 'Look you,' says the huntsman, 'hereabout it was she kennelled; look you, here it was indeed, for here's her young ones, no less than five; come, let's kill them all.' "No," exclaims Piscator, "I pray, Sir, save me one, and I'll try if I can make her tame, as I know an ingenious gentleman in Leicestershire, Mr. Nich. Seagrave, has done; who hath not only made her tame, but to catch fish, and do many other things at pleasure.' Buffon, who could be as hard of belief in some points as he was credulous in others, disbelieves the otter's capability for domestication. The testimony above noticed has been confirmed by a cloud of modern witnesses. Goldsmith mentions an otter which went into a gentleman's pond at the word of command, drove the fish up into a corner, and having seized on the largest, brought it out of the water to its master. Daniel, Bewick, Shaw, record instances of the animal's docility in this way. Mr. Bell and Mr. Macgillivray both corroborate the fact. The latter has collected the following anecdotes. 'Mr. M'Diarmid, in his amusing "Sketches from Nature," gives an account of several domesticated otters, one of which, belonging to a poor widow, when let forth, plunged into the Urr or the neighbouring burns, and brought out all the fish it could find. Another, kept at [illegible] House, Wigtonshire, evinced a great fondness for [illegible], fondled about her keeper's feet like a pup or kitten, and even seemed inclined to salute her cheek, when permitted to carry her fondness so far. A third, belonging to Mr. Monteith of Carstairs, was also very tame, and though he frequently stole away at night to fish by the pale light of the moon and associate with his kindred by the river side, his master, of course, was too generous to find any fault with his peculiar mode of spending his evening hours. In the morning he was always at his post in the kennel, and no animal understood better the secret of keeping his own side of the house. Indeed his pugnacity in this respect gave him a great lift in the favour of the gamekeeper, who talked of his feats wherever he went, and vowed besides that if the best dog that ever ran "only ventured to gurr" at his protégé, he would soon "mak' his teeth meet through him." To mankind however he was much more civil, and allowed himself to be gently lifted by the tail, though he objected to any interference with his snout, which is probably with him the seat of honour.' They are however dangerous pets; for, if offended, they will bite grievously.

Utility to Man.—The capability of the Otter for domestication being proved, there is no doubt that the animal might be trained to catch fish or assist in fishing. For this purpose Mr. Bell states that the following method has been recommended:*—they should be procured as young as possible, and be first fed with small fish and water. Then bread and milk is to be alternated with the fish, and the proportion of the former gradually increased till they are led to live entirely on bread and milk. They are then taught to fetch and carry, as dogs are trained, and when they are brought to do this well, a leather fish stuffed with wool is employed as the thing to be fetched. They are afterwards exercised with a dead fish, and chastised if they attempt to tear it. Finally they are sent into the water after living fish.

As an article of food, though the flesh is rank and fishy, the otter was not rejected by the Roman Catholics. Their church permitted it to be eaten on maigre days; and Pennant saw one in the kitchen of the Carthusians near Dijon, under preparation for the dinner of the religious of that rigid order, who, by their rules, are prohibited during their whole lives from eating flesh. Mr. Macgillivray states that he knew a man in Harris who procured a considerable number every year, when the skins were more in request than now, and who generally cooked the flesh, of which Mr. Macgillivray once partook with the family. It was 'dark-coloured, rank, sapid enough, but not agreeably so;' and under the skin was a layer of fat, as in the seals, which might, he adds, render it pleasant food to a Greenlander or starving Hebridian.

Varieties.—Before we refer to the undoubted *varieties* of this species, it is necessary to notice an *Irish Otter*, which Mr. Ogilby has elevated to the rank of a species, under the name of *Lutra Roensis*, on account of the intensity of its colouring, which approaches nearly to black both on the upper and under surface; of the less extent of the pale colour beneath the throat, as compared with the English *Lutra vulgaris*; and of some difference of the ears, and in the proportions of other parts. The marine habits of the animal, which is found chiefly in hollows and caverns formed by scattered masses of the basaltic columns of the east coast of Antrim, where a price is set upon its head in consequence of its destruction of the salmon, strengthen Mr. Ogilby in this opinion, from which Mr. Bell differs, observing that Mr. Ogilby states that he had not had an opportunity of comparing it with the *Common Otter*, that he (Mr. Bell) does not find in the stuffed specimen presented by Mr. Ogilby characters sufficiently distinct to lead to the belief that it is more than a very dark and handsome variety, and that two skins of Zetland otters (which are equally marine in their habits) presented to him (Mr. Bell) are almost as dark-coloured; Mr. Bell adds that these skins are larger than those usually found in England; and that the fur is nearly as fine as those imported from America.

The variety spotted with white is supposed to be the 'King of the Otters' of the Scotch vulgar, who hold that it bears a sort of charmed life, in so far that its death is never unaccompanied by the death of a man or some other living creature. The skin is considered precious as an antidote against infection, wounds, and the dangers of the sea. One of these spotted otters is in the museum at Paris, near which place it was found. Mr. Macgillivray says that he has heard of white otters, but had never seen an albino.

Chase.—In the older annals of sporting in this country, otter-hunting holds no inconsiderable place. Somerville describes it at some length and with much unction in his fourth book (*Chace*) towards the end. It is now fast dying away; but is still kept up in some places, as in Wales and Scotland. The pretty vignette at the close of Mr. Bell's interesting history of the Otter† was taken as one of the mementoes of a day's sport in Glamorganshire not long ago. Mr. Macgillivray‡ informs us that Mr. Lomax hunted the Dumfriesshire rivers in 1833, 1834, and 1835, and that

* See Goldsmith.

† 'British Quadrupeds,' 1837.

‡ 'Naturalist's Library—Mammalia,' vol. vii., 1838.

Lord John Scott keeps a pack of otter-hounds for the streams of Roxburghshire.

Geographical Distribution.—Europe generally.

Lutra vulgaris.

ASIATIC LUTRÆ.

Example, *Lutra Nair.*

Description.—Fur deep chestnut, lightest on the sides; lower part of the neck and cheeks, as well as the throat, reddish bright brown; above the eye a ruddy yellow or yellowish-white spot.

This is the *Nir-nayie* of the people of Pondichery, and is probably the species seen by Bishop Heber, who passed a row of nine or ten large and very beautiful otters, tethered with straw collars and long strings to bamboo stakes on the banks of the Matta Colly. 'Some were swimming about at the full extent of their strings, or lying half in and half out of the water; others were rolling themselves in the sun on the sandy bank, uttering a shrill whistling noise as if in play. I was told that most of the fishermen in this neighbourhood kept one or more of these animals, who were almost as tame as dogs, and of great use in fishing; sometimes driving the shoals into the nets, sometimes bringing out the larger fish with their teeth.' Another proof, if any were wanting, of the feasability of taming these animals and rendering them useful to man.

Geographical Distribution.—East Indies. N.B. Colonel Sykes notes, in his list of *Mammalia* obtained in Dukhun (Deccan), '*Lutra Nair*, F. Cuv., *Juhl Marjur* or *Water-Cat* of the Mahrattas. The *Otter* of Dukhun differs only from the *Nair* in wanting the white spots over the eyes, in having a white upper lip, and in being somewhat larger.' (*Zool. Proc.*, 1830-31.)

AFRICAN LUTRÆ.

Example, *Lutra Capensis* (genus *Aonyx* of Lesson).

Description.—Fur soft, full, and thick, chestnut brown, deepest on the rump, limbs, and tail, brighter on the sides, and brownish-grey upon the head; under part of the body white. Length two feet ten inches from the muzzle to the tail, which is one foot eight inches.

Observations.—M. Lesson allows that this species, which he has elevated to the rank of a genus, possesses the same general characters as the *Lutræ*, such as the dentary system and form of the body; and makes the difference solely consist in the form of the feet and toes, which he says are hardly joined by a membrane. He states that the second toe would seem conjoined to the third throughout its first articulation. These toes are both more elongated than the succeeding ones, and all the toes are without claws, or rather, a vestige of a rudimentary nail is only observed on the second and third toes of the posterior feet. He records the species as *Aonyx Delalandii*, Lutra inunguis of G. Cuv. and F. Cuv., *Dict. Sc. Nat.* But Cuvier, in his last edition of the 'Règne Animal,' writing on the Cape Otter (*Lutra Capensis*, Fr. Cuv.), remarks that the white of the throat, the sides of the head, and of the neck is more pure than [illegible] Javanese *Simung* (*Lutra Leptonyx*, Horsf.), and [illegible] some of this colour at the end of the nose; but, [illegible]t most distinguishes it is that (at a certain [illegible]) it has no nails, a character on which M. Lesson [illegible] the genus *Aonyx*. Nevertheless, continues Cuvier in conclusion, young individuals have been brought from the Cape which have nails, and it remains to be proved whether these are of the same species.

Locality, Habits, Food, &c.—This species haunts the salt pools of the sea-shores of the Cape, and lives on fish and crustaceans.

AMERICAN LUTRÆ.

Examples, *Lutra Canadensis* and *Lutra Brasiliensis.*

Lutra Canadensis, Sabine.

Description.—Fur above and below shining brown, and much resembling that of the beaver. Size much larger than that of the European Otter, *Lutra vulgaris.* Length from nose to tip of tail (which is eighteen inches) about five feet.

This is the *Loutre de Canada* of Buffon, *Land Otter* of Warden, *Common Otter* of Pennant (*Arct. Zool.*); *Lutra Brasiliensis* of Harlan; the *American Otter* of Godman; *Neekeek* of the Cree Indians; and *Capucca* of the inhabitants of Nootka.

Dr. Richardson, who gives these synonyms, states succinctly the various opinions of authors as to this species, and concludes by following Mr. Sabine's opinion that it is peculiar to the northern districts of America.

Habits, Food, &c.—In its habits and food Dr. Richardson states that the Canada otter resembles the European species. In the winter season it frequents rapids and falls for the advantage of open water; and when its usual haunts are frozen over, it will travel to a great distance through the snow in search of a rapid that has resisted the frost. When seen and pursued by the hunters as it is on these journeys, it throws itself forward on its belly and slides through the snow for several yards, leaving a deep furrow behind it. This movement is described by the Doctor as being repeated with so much rapidity, that even a [illegible] runner on snow-shoes has much trouble in overtaking it. It also doubles on its track with much cunning, and dives under the snow to elude its pursuers. When closely pressed, it will turn and defend itself obstinately. When Dr. Richardson's party were at Great Bear Lake, in the spring of 1826, these otters robbed their nets which had been set under the ice a few yards from a piece of open water. They generally carried off the heads of the fish, leaving the bodies sticking in the net.

The female brings forth one litter in the year, consisting of two or three.

Geographical Distribution.—The Mackenzie a[illegible] rivers nearly to the Arctic Sea; and Dr. Richardson [illegible] that there appears to be no difference between the [illegible] obtained on the shores of the Pacific and those in the neighbourhood of Hudson's Bay. (*Fauna Boreali-Americana.*)

Utility to Man.—The fur is valuable, and a cons[illegible] article of commerce; it varies with the season. In s[illegible] the hair is very short, and then it is almost black; [illegible]ter it becomes a rich reddish brown, with the exception of the greyish spot under the chin. The fur is nearly [illegible] as beaver-wool, but not so long, and consequently [illegible] well adapted for felt. Dr. Richardson says that se[illegible] eight thousand are annually exported to England.

Lutra Brasiliensis, Ray.

Description.—Fur short and close, of a bright red[illegible]low deepening into chestnut towards the extremity [illegible] limbs and tail; lower part of the neck and throat [illegible]low. Length, male, 3 feet 6½ inches; tail, which [illegible] thick, 18 inches. The largest female possessed [illegible] D'Azara was 34 inches long including the tail, which [illegible] inches. Another measured 36 inches, 12 for the tail.

Obs.—M. Lesson states that this is the only otter [illegible] is deprived of the glandular apparatus round the [illegible].

This is the *Lobo de rio* (River Wolf) of the [illegible] but D'Azara observes that it is not a wolf, but a[illegible] belonging to the same family as the European [illegible] from which it differs; and he accordingly calls it [illegible]. It is the *Mustela Lutra* (*Brasiliensis* β.) of Gmelin.

Habits, Food, Reproduction, &c.—D'Azara says that [illegible] species lives in troops, which sometimes, rising to the [illegible]face of the water, lift their heads and bark like dogs [illegible] a hoarse voice, in a menacing and snapping manner, [illegible] however injuring voyagers or swimmers. Each [illegible] seems to possess a separate domain. It spends as much time in the water as it does upon land, where [illegible]vours the fish which it has taken, and rears its young [illegible] holes which it excavates in the banks. The same a[illegible] we informed by the Payaguas Indians, who sail continually up and down the river, and are better acquainted with this animal than others, that the female brings forth two at a birth, covered with hair, and that many females bring forth and rear their young at the same time and in the same place, their usual resort throughout the year. The motions of this Otter are generally slow, and it drags, as it were, its belly and muzzle along the ground; when it runs it is not at all swift.

D'Azara further states that a neighbour of his purchased a young whelp, which at six months old was 34 inches long. It was permitted to run loose about the house, and was fed with fish, flesh, bread, mandioca, and other food, but it preferred fish. It would walk into the stoves and rooms, knew the people of the house, came when called by name, and would follow them like a dog, but its short legs soon tired it, and it soon grew weary. It would amuse itself with dogs and cats as well as with their masters; but it was a rough playfellow, and required to be treated cautiously, for it bit sharply. It never harmed poultry or any other animal, excepting sucking pigs, which were not safe within its reach, and it would have killed them, if it had not been prevented. It entered all the rooms and slept always below the bed, was very cleanly, and always visited one particular spot for the deposit of its excrements.

Locality.—The lakes, rivers, and rivulets of Paraguay, according to D'Azara, who at first stated that he did not believe that it entered salt water, and that its geographical range did not extend to the river Plata; but in his French [illegible] he states that the species is found in that river.

*** From M'Culloch's lists it appears that the number of Otter-skins exported from Quebec in 1808 amounted to 7000, at 1*l.* per skin. In 1826 the numbers were less, 1090 having been exported from that place in that year. In 1831, 14,863 were imported into Britain: of these 39 came from Germany, 13,104 from the British North American Colonies, 1707 from the United States, 2 from Buenos Ayres, and 11 from all other places. They were almost wholly re-exported to Germany and the Netherlands. Mr. [illegible] states that the number of Otter-skins imported into this country in 1830, was 713,115; in 1831, 494,087; in 1832, 222,393; and in 1833, only 22,536. He adds that since September 1, 1833, the duty was reduced from 1*d.* each to 1*s.* per hundred, since which he believes that the importation has gradually increased.

Enhydra.

Dr. Fleming gives the following generic character of the Sea-Otter under the above name. Six incisors above, and four below. Tail much shorter than the body. No anal appendages.

Obs.—In Cook's 'Voyage' it is stated that a young Sea-Otter was brought on board with *six lower* incisors. Steller and succeeding systematists give four as the number in the lower jaw. Dr. Richardson suggests that two of the lower ones may drop out before the animal becomes adult.

Description.—Fur thick, woolly, and very soft, with the addition of a few silky hairs of a lustrous black; most of the upper parts are of a deep velvety maroon brown, and the anterior parts silvery gray. Body elongated; tail short and stout; hinder feet very short.

This is the *Sea Beaver* of Krascheninikoff; the *Sea-Otter* of Cook, Pennant, Meares, Menzies, and Godman; the *Kaiku* of the Kamtchatdales; *Mustela Lutris* of Linnæus; *Lutra marina* of Steller, Erxleben, and Harlan; *Loutre du Kamtschatka* of the French; *Enhydra marina* of Fleming. (*Richardson.*)

Captain Cook, in his last voyage (chapter on King George's Sound, Nootka), says, 'It might have been sufficient to have observed that this animal (the sea-otter) abounds here, as it is fully described in different books, taken from the accounts of the Russian adventurers in their expeditions eastward from Kamtchatka, if there had not been a small difference in one that we saw. We for some time entertained doubts whether the many skins which the natives brought really belonged to this animal; as our only reason for being of that opinion was founded on the size, colour, and fineness of the fur; till a short while before our departure, when a *whole one*, that had been just killed, was purchased from some strangers who came to barter; and of this Mr. Webber made a drawing. It was rather young, weighing only twenty-five pounds; of a shining or glossy black colour; but many of the hairs being tipt with white gave it a greyish cast at first sight. The face, throat, and breast were of a yellowish white or very light brown colour, which in many of the skins extended the whole length of the belly. It had *six cutting teeth in each jaw; two of those of the lower jaw being very minute*, and placed without, at the base of the two middle ones. In these circumstances it seems to disagree with those found by the Russians; and also in not having the outer toes of the hind feet skirted by a membrane. There seemed also to be a greater variety in the colour of the skins than is mentioned by the describers of the Russian Sea-Otters. These changes of colour certainly take place at the different gradations of life. The very young ones had brown hair, which was coarse, with very little fur underneath; but those of the size of the entire animal, which came into our possession, and just described, had a considerable quantity of that substance, and both in that colour and state the Sea-Otters seem to remain till they have attained their full growth. After that they lose the black colour, and assume a deep brown or sooty colour; but have then a greater quantity of very fine fur, and scarcely any long hairs. Others, which we suspected to be still older, were of a chestnut brown; and a few skins were seen that had even acquired a perfectly yellow colour. The fur of these animals, as mentioned in the Russian accounts, is certainly softer and finer than that of any others we know of; and therefore the discovery of this part of the continent of North America, where so valuable an article of commerce may be met with, cannot be a matter of indifference.'

Habits, Food, Reproduction, &c.—The sea-otter haunts sea-washed rocks, lives mostly in the water, and approximates to the seals more than to the otters in its habits. The food is fish. The female brings forth on land, and notwithstanding the general marine habits of the animal, it has been occasionally seen very far from the shore.

Geographical Distribution.—The North Pacific, from Kamtchatka to the Yellow Sea on the Asiatic side, and from Alaska to California on the American coast. (*Richardson.*)

Utility to Man.—The fur was eagerly sought after, and is still prized, but not so highly as formerly. Coxe quotes Pallas for the fact that the old and middle-aged sea-otter skins were sold at Kiachta, by the Russians, to the Chinese, at from 80 to 100 roubles a skin, or from 16*l.* to 20*l.* each. Dr. Richardson observes that the trade was for a considerable period in the hands of the Russians, who, soon after the discovery of the north-west coast of America by Behring and Tschirikow, sent mercantile expeditions there. The passage above quoted from Captain Cook's 'Third Voyage' drew the attention of the English, and both private merchants and the India Company sent vessels to collect skins on the American coast and transport them to Canton. Pennant's hint at the profitable trade which might be carried on with China by a colony, were it possible to penetrate to that part of America by means of rivers and lakes, seems not to have been lost. Sir Alexander Mackenzie having traversed the continent of America and reached the Pacific, his partners in trade established fur posts in New Caledonia and a direct commerce with China; but, as Dr. Richardson remarks in conclusion, the influx of furs into that market soon reduced their price.

[illegible]

Place in the System.—Linnæus placed the Otters among the Weasels, as species of the genus *Mustela;* and modern authors generally have assigned to the form a place among the *Mustelidæ.*

In Illiger's system we find *Lutra* in his family *Gracilia* (in company with *Herpestes, Mephitis,* and *Mustela*), the fourth of his order *Falculata.*

Cuvier and Geoffroy place the form between the genus *Mephitis* (subgenus *Mydaus*) and *Canis.*

Mr. Gray arranges *Lutra,* together with *Putorius,* &c., under his subfamily *Mustelina,* the third of his family *Felidæ. Enhydra* of Fleming (which that zoologist had removed, together with *Lutra,* to his *Palmata,* so as to unite them to the Seals) forms the subfamily *Enhydrina* of Gray (which is situated between *Phocina* and *Otariina*), being the third of Mr. Gray's family *Phocidæ.*

Fischer (J. B.) places *Lutra* between *Mustela* and *Enhydris,* which last is immediately succeeded by *Phoca.*

Lesson follows Cuvier and Geoffroy.

Mr. Swainson arranges *Lutra* (with *Enhydra* as a subgenus) between *Mydaus* and *Gulo,* in his subfamily *Mustelinæ,* family *Mustelidæ.* He considers that the otters, although intimately connected with the polecats, clearly form the aquatic type of the *Mustelinæ,* and as such represent the seals.

Mr. Bell keeps *Lutra* in the family *Mustelidæ,* and in Mr. Macgillivray's *British Quadrupeds* the genus stands next to the marten.

Fossil Otters.

Jæger notices the remains of a *Lutra* in the Bean iron-ore (Bohnerz) of the Rauh Alp (tertiary); and MM. de Serres, Dubrueil, and Jean-Jean record an extinct species (*Lutra antiqua*) in the bone-caverns of Lunel-Vieil. The form was also detected in the Puy-de-Dome by MM. Croizet and Jobert.

OTTER-HOUND, a variety of hound employed in the chace of the otter. As it is necessary that otter-hounds should not only have good noses, but take the water freely, some care is necessary in attending to the breed, if a good pack is to be the result. Mr. Daniel recommends a cross between the harrier and terrier. [Otter.]

OTTERY ST. MARY. [Devonshire.]

OTTOMAN EMPIRE. [Turkey.]

OTUS, Cuvier's name for a genus of Horned Owls. [Strigidæ.]

OTWAY, THOMAS, an eminent English dramatist, was born at Trotten, in Sussex, March 3rd, 1651. He received his education at Winchester school, and was entered a commoner of Christ-Church, Oxford, in 1669. Having left the University without a degree, he went to London, where he commenced player, but met with little success on the stage. The fame which was denied to him as an actor he endeavoured to obtain as an author, and in 1675 he produced 'Alcibiades,' the first of his tragedies. In the same year his 'Don Carlos, Prince of Spain,' made its appearance, of which the popularity was so great that it is said to have been played for thirty nights in succession, and to have produced considerable emolument to the writer. 'Titus and Berenice' and the 'Cheats of Scapin' were published in 1677, the first of which was translated from Rapin, and the latter from Molière. 'Friendship in Fashion' was published during the following year.

Otway's wit procured for him the patronage of the earl of Plymouth, and a cornetcy was obtained for him by this nobleman in the army of Flanders. Not finding the military life agreeable, he gave up his commission, and returned to London, where, being in extreme poverty, he again began to write for the stage. 'The Orphan,' one of the most pleasing of all his plays, was performed in 1680, as was also the 'History and Fall of Caius Marius.' In 1681 appeared the first part of a comedy called the 'Soldier's Fortune,' which was completed by the addition of a second part under the title of 'The Atheist,' in 1684. The greatest of all his dramatic efforts however was his last, 'Venice Preserved,' which was exhibited in 1682, and which still keeps possession of the stage. Its character is altogether of a higher order than that of any of his other performances. Besides the works that have been mentioned, Otway was the author of various translations and numerous miscellaneous poems. An edition of his whole works was published in 3 vols. 12mo., in 1757; and another in 4 vols. 8vo., in 1813. His writings, although so numerous, did not secure him from the miseries of indigence; and one of the accounts of his death, which are various, represents it as having been occasioned by hunger. He died April 14th, 1685, before he had reached his 34th year. As an author, he shows great tenderness and command over the gentler feelings, and an exact knowledge of human nature. Passages of considerable power also are of frequent occurrence in his writings, which however are disfigured by a prevalent grossness and immorality. (Works, Lond., 1757, 3 vols. 12mo.; Lond., 1813, 4 vols. 8vo.)

OUDE. [Hindustan, vol. xii., p. 218.]

OUDENAARDEN, commonly called *Oudenarde,* and by the French, *Audenarde,* a fortress and town of East Flanders, 15 miles south-south-west from Ghent, on the right bank of the Schelde, in 50° 51′ N. lat. and 3° 35′ E. long. The town is a place of great trade. It is the centre of a district in which the linen manufacture is carried on, and is the market in which the products are sold; it contains also several tanneries, breweries, salt-refineries, works for dyeing and bleaching, some cotton-mills, oil-mills, and various other manufacturing establishments. The town contains 765 houses and 5407 inhabitants. It has three churches, a town-hall, an hospital, two orphan-houses, 17 schools, and a college. There is besides, a school, opened in 1833, in which 150 boys and an equal number of girls are taught gratuitously. There is also an industrial school for poor girls, in which they are taught to sew and to knit, which contains about 100 children.

The houses are generally well-built. The town is of great antiquity, but the date of its origin is quite unknown. It is believed that the Romans made it a station of importance, which is corroborated by the great number of Roman medals and coins which have from time to time been discovered on the spot. In one part of the town, where the remains of some very old buildings are to be seen, there were found statues of Domitian, Antoninus Pius, Marcus Aurelius, and Commodus. Some Flemish historians, on the other hand, date the origin of the town from the beginning of the fifth century. The prosperity of Oudenarde dates from the time of Philip of Alsace, count of Flanders, who enclosed it and gave great privileges to the citizens. A great battle took place before this town in 1708, between the French, commanded by the Duke of Burgundy, and the allies under Marlborough and Prince Eugene, in which the latter gained a complete victory.

Oudenarde is the birth-place of the learned Drusius and of Adrian Brauwer, one of the best painters of the Flemish school.

OUGHTRED, WILLIAM, an English divine and mathematician, born at Eton, in Buckinghamshire, in 1573. Cole says that he was educated at the school upon its foundation there, and was elected thence, in 1592, to King's College, Cambridge, of which, in regular course, he became a Fellow. While he was an undergraduate he invented 'an easy method of geometrical dialling,' but which was not given to the public before the year 1647. He proceeded to the degree of B.A. in the year 1596, and that of M.A. in 1599. In the year 1603 or thereabouts, Oughtred was ordained priest, and presented to the rectory of Aldbury, near Guildford in Surrey, upon which appointment he quitted the University and resided upon his living, distinguishing himself by the faithful and diligent discharge of his pastoral duties. In 1628 he was engaged by the earl of Arundel to become tutor to his son, Lord William Howard, the nobleman whose patronage of science holds a distinguished position in the history of its progress during the seventeenth century. But notwithstanding his high station in the scientific world (and Fuller says that he was 'unanimously acknowledged the prince of mathematicians'), he was in danger, in the year 1646, of a sequestration by the committee for plundered ministers, several articles having been deposed and sworn against him, material enough, it is said, to have sequestered him. But upon his day of hearing, William Lilly, the famous astrologer, applied to Sir Bulstrode Whitlocke and all his old friends, who appeared in such numbers on his behalf, that he was acquitted by the majority. Oughtred sometimes amused himself with archery; he was sprightly and active at the age of eighty, and, if we may believe Mr. Collier, died in an ecstasy of joy upon hearing of the restoration of Charles II. Fuller (*Worthies,* i. 145) says that 'this aged Simeon had a strong persuasion that before his death he should behold Christ's anointed restored to the throne, which he did accordingly to an incredible joy, and then had his *dimittis* out of this terrible life, Jan. 30th, 1660.' Evelyn, in his 'Diary' of 28th August, 1655, mentions meeting with Mr. Oughtred, 'the famous mathematician,' which shows that his fame was well established.

The following is a list of his principal works:—

1. 'Arithmeticæ in Numeris et Speciebus Institutio; quæ tum Logisticæ tum Analyticæ, atque adeo totius Mathematicæ quasi Clavis est,' 12mo., 1631.

This work passed through many editions, and an English translation of it was made by Christopher Wren, and published under the title of 'The Key of the Mathematics new forged and filed.' It was introduced by Seth Ward as a text book at Cambridge. The book was much complained of by some on account of its style, but Dr. Wallis says, 'without cause, for his words be always full, but not redundant;' and Dr. Pell, in a letter in Cavendish preserved in MS. Harl. Mus. Brit., 6796, bears witness to the same effect.

2. 'The Description and Use of the Double Horizontal Dyall, whereby not only the hower of the day is shewne, but also the meridian line is found; and most astronomical questions which may be done by the globe are resolved,' 12mo., 1636.

Another edition appeared in 1652.

3. 'A Treatise on Trigonometry,' 4to., 1657.

This book was afterwards published in Latin, in 1667, by Stokes and Haughton.

We refer for more particulars concerning Oughtred to Aubrey's 'Lives' and MS. Addit., Mus. Brit., 4221. Many of his papers are now in the valuable library of the Earl of Macclesfield.

OUTLAWRY. This term, which is derived from the Saxon *Utlagh* or *Uthlagh*, signifies an exclusion from the benefits and protection of the law. In English law it is a punishment consequent upon a flight from justice, or a contumacious neglect or refusal to appear and answer for a civil or criminal transgression, in obedience to the process of a court of competent jurisdiction. By the laws of the Anglo-Saxons, continued after the Conquest, an outlaw, who was also called *laughlesman* (lawless man) and *frendlesman* (friendless man), lost his *liberam legem*, and had no protection from the frankpledge in the decennary in which he was sworn. A boy under twelve years of age, not being sworn to his law in the decennary, could not be outlawed; and for the same reason a woman who contumaciously refused to appear could not be outlawed, but was said to be *waived* (*derelicta*), and incurred the same penal consequences as an outlaw.

For centuries after the Conquest an outlaw was said '*Gerere* caput lupinum,' and might be lawfully killed by any one who met him. It is stated in the 'Mirror' (cap. iv., sec. 2) to have been the custom for those who slew outlaws or wolves to 'carry the heads to the chief place of the county or franchise, and there to receive a demi-mark from the county for each head, whether of an outlaw or a wolf.' The 'Mirror' is a book of doubtful antiquity and authority, and this story of the reward for the heads of outlaws is probably fabulous, or at all events an exaggeration of the fact. Bracton, who wrote about the end of the reign of Henry III., and therefore more than two centuries after the Norman Conquest, declares that an outlaw 'might be killed by all, especially if he defended himself or ran away, so that it was difficult to take him; but that when once taken, his life and death were in the king's hands; and if any man then killed him, he must answer for it as in the case of any other homicide.' (Bracton, lib. iii., cap. 13.) That this practice and law prevailed in his time is further proved by another passage in Bracton (lib. iii., c. 14), in which he says that a man who has been outlawed, but has become 'inlegatus,' or restored to his law by a pardon from the king, should take care always to 'carry his pardon about with him wheresoever he may go, and have it ready in his hand to show, lest peradventure some person, not knowing that he has obtained the king's grace, should slay him as an outlaw.' Fleta, who wrote rather later than Bracton, mentions the same law, and justifies it; 'Utlagatus et waiviata capita gerunt lupina, quæ ab omnibus impune poterunt amputari; merito enim sine lege perire debent qui secundum legem vivere recusant.' (Fleta, lib. i., cap. 27.) Lord Coke says, 'In the beginning of the reign of Edward III. it was resolved by the judges, for avoiding of inhumanity and effusion of Christian blood, that it should not be lawful for any man but the sheriff only (having lawful warrant therefore) to put to death any man outlawed, though it were for felony; and if he did, he should undergo such punishments and pains of death as if he had killed any other man; and so from thenceforth the law continued until this day.' (Co. Litt., 128 *b*.) For this fact he refers to the 'Year Book,' 2 Ass., pl. 3. The 'Year Book' however, so cited, and another report of the same case in Fitzherbert's 'Abridgement,' tit. Corone, 142, contain no such resolution, and the case from which it is obvious that Lord Coke derived the above statement, is clearly no authority to show the continuance of the old practice. A man being arraigned for homicide objects to answer, because the person with whose death he was charged had been outlawed for felony. The judges at first certainly appeared to think that it was not lawful for any one to kill an outlaw unless it were upon his resisting a bailiff who should attempt to arrest him. But after argument, they said they 'must send to the chancery to enquire if the deceased had a charter of pardon, and search their own rolls to see if his outlawry has been reversed;' and they admitted the prisoner to bail in the mean time, telling him that if they found that there had been no pardon and no reversal of the outlawry, he would not be called upon to answer. This case therefore seems to show that Lord Coke prematurely claimed for the judges in the reign of Edward III. the merit of abolishing this barbarous practice; indeed so late as the reign of Philip and Mary, Staundforde, in his 'Pleas of the Crown,' mentions the above case, and speaks of the law upon this subject as doubtful. However, though the technical quality of homicide so committed may have been questionable, there is no doubt that the practice of killing outlaws like wild beasts had ceased long before Staundforde's time.

The consequences of outlawry are the forfeiture of goods and chattels universally. Where it takes place upon a prosecution for *treason or felony*, it amounts to a conviction and attainder of the offence charged, and therefore all the outlaw's real property, as well as his personalty, is forfeited. Where it takes place upon criminal prosecutions for misdemeanors, or upon civil actions, the profits only of the defendant's lands are, during his life, forfeited to the crown. The outlaw, having neither the privilege nor protection of the law, is incapable of maintaining any action real or personal; at the common law he could not be a juror, as he was not 'liber et legalis;' and he is expressly excluded from acting as a juror by stat. 6 Geo. IV., c. 50, sec. 3.

The consequences of outlawry being so highly penal, the law has at all times been careful that no person shall be outlawed without sufficient notice of the process of the court, and without satisfactory proof of his contumacy. It is therefore required, in the first place, that in all civil cases, and in all indictments for misdemeanors, and probably also for felonies not capital, three consecutive writs of capias, each issuing upon the return of the former one, should be directed to the sheriff of the county in which the proceeding is commenced. If upon all these writs the return is non est inventus, a writ of *exigent* or *exigi facias* is sued out, which requires the sheriff to cause the defendant to be called or *exacted* in five successive county courts, or in five successive hustings, if in London; and if he renders himself, to take him. But if he does not appear at the fifth county-court or husting, judgment of outlawry is forthwith pronounced against him by the *coroners*, who are the judges for this purpose in the county-court, and by the recorder if the proceedings are in London (Co. Litt., 288 *b*; Dyer, 223 *a*, 317 *a*); and the fact of such judgment having been given is returned by the sheriff upon the exigent. Upon this return a writ of capias utlegatum may be issued into any county to arrest the defendant, and other process follows against his property. As an additional security that a man shall not be outlawed without notice of the process to which he is required to appear, the several statutes provide that a writ of proclamation shall issue at the same time with the exigent into the county where the defendant dwells, commanding the sheriff to make three proclamations of him in notorious places in the county a month before the outlawry shall take place.

The only difference between the proceedings in outlawry upon an indictment of treason or capital felony and those upon civil actions and prosecutions for inferior crimes, is that one capias is in the former case sufficient before the award of the exigent.

An outlawry may be reversed by writ of error, in which the party may avail himself of errors either of law or fact; and the slightest mistake in any part of the proceedings will avoid the outlawry. It was formerly necessary to procure a pardon from the crown, by which the outlaw was restored to his law, and became to all intents and purposes 'inlagatus.' In modern times it is the usual course for the courts to reverse outlawries upon motion, without obliging the parties to sue out writs of error or procure pardons, and by this practice justice is expedited and expense saved.

OVATION. [Triumph.]

OVERBURY, SIR THOMAS. [James I.]

OVERSEER, an officer appointed by justices of counties or boroughs, for parishes under the 43 Eliz., 2, and for townships under the 13 & 14 Car. II., 12. They cannot be less than two nor more than four for one parish or township. Churchwardens are ex-officio overseers of the poor. The duties of an overseer and of an assistant-overseer are identical, the latter being a paid officer, appointed under the 59 Geo. III., 12, where, on account of the amount of the population, the extent of the parish, or other difficulties, the services are onerous and troublesome. Before the passing of the Poor-Law Amendment Act, it was the business of an overseer as well to appropriate and distribute as to make out and collect the poor-rates. Where no select vestry existed, he was judge of the necessities of applicants for and receivers of parochial relief, an appeal in case of refusal lying before magistrates in petty sessions. For an account of the abuses which arose from the trust the law formerly confided to overseers, see the article Poor-Law. We will now describe the present duties of an overseer in parishes subjected to the operation of the Poor-Law Amendment Act: 1, Relating to the management of the poor and to the boards of guardians of the district; 2, With respect to returning lunatic and jury lists; 3, With reference to the registration of voters.

1. The Poor-Law Amendment Act limited the authority of an overseer of the poor, by transferring to a board of guardians such portion of his duties as related to ascertaining fit objects for parochial relief, the amount of relief to be given, and the manner of giving it. With such services he has now little to do. His first business on entering upon his office is to possess himself as soon as he is able of the parish books and documents, including all orders of bastardy under which money is payable; to collect outstanding arrears, if any; and to settle the balance with the outgoing overseer. He will probably be soon called upon to levy a rate, which must be made by a majority of parish-officers. On refusal by any party to pay the rate being sworn to by the overseer, a summons will be granted against the defaulter by a magistrate. An appeal may be carried by the rate-payer to the district petty sessions, on the ground of inequality, unfairness, or incorrectness, if at least seven days' notice be given to the collector or overseer under the hand of the party appellant; or to the quarter-sessions, on the ground that the property is not rateable. It is then the duty of the overseer to appear before the justices to support the validity of the rate. He must collect all arrears that he is able from the fathers of bastard children, and keep the weekly payments from them currently paid up. In cases of refusal to pay, or other difficulties, he should apply to the Board of Guardians for advice before taking the proceedings justified by law. He is only to give relief to the poor 'in any case of sudden or urgent necessity;' and, as soon as he is able, is to report to the relieving-officer his having given such relief. The relief may not be given in money, but only in articles of absolute necessity. The orders of the Poor-Law Commissioners further set forth, that 'If any overseer shall receive an order directing relief to be given to any person (duly certified, under the hand and seal of one of the signing justices, to be of his own knowledge wholly unable to work), without requiring that such person shall reside in any workhouse, he shall forthwith transmit the same to the relieving officer of his township or place, to be laid before the Board of Guardians at their next meeting.' At the end of each quarter the overseer will receive a notice from the auditor of the union to attend him, that his accounts may be examined and audited. At these times he should take with him all his parish books, letters, and papers, to any of which reference may possibly be made. He is to manage and collect the rents of parish property; and at the end of the Michaelmas quarter he should make out a 'terrier of the lands and tenements, and an inventory of stock, moneys, goods, and effects belonging to such parish or place, or given or applicable in aid of the poor-rates thereof.' The accounts of overseers must be submitted to two magistrates for their examination within fourteen days after the 25th of March. The proceedings for the election of a guardian or guardians in their district are likewise conducted for the most part by the overseer. He must distribute and affix the notices, receive the names of candidates, and, if there be a contest, circulate voting-papers, receive the votes, and return the names of the successful candidate or candidates, according to the forms of the Poor-Law Commissioners and the provisions of the 4 & 5 William IV., cap. 76. (See clauses 38-41 of the *Poor-Law Amendment Act.*)

In cases in which affiliation seems desirable, or respecting orders of removal from his parish, or notices received of orders of removal to it, the overseer should hear the opinion of the Board of Guardians at their next ensuing meeting. He will likewise receive instructions, if he is ignorant or doubtful of the forms which must be complied with in such cases.

2. At their first petty-sessions after the 15th of August, the justices of the district issue their warrants to the overseers to return lists of all insane persons chargeable in their respective parishes. It is the duty of the overseer to make this return, as well as, in the case of any insane person becoming chargeable, to give notice within seven days to some magistrate acting for that division of the county. In July he will receive from the high-constable of the division a precept, containing full information of his duty respecting the return of a list of persons liable to serve on juries. This return is to be made before the 1st of September.

3. With regard to registration, his business is as follows. On the 20th of June in each year, he will affix on the church door a notice, directing fresh claimants for votes to make formal claim in writing to the overseer on or before the 20th of July. His next step is to make out for each parish an alphabetical list of the names of all persons already in the register, together with those of all claimants. This list must be completed by the last day of July, and affixed on the church or chapel, and, if there be no church or chapel, in some conspicuous situation, on the two first Sundays in August. He must give copies of this list for a reasonable payment, if required. On or before the 25th of August, objections to votes may be received. An alphabetical list of objections is to be posted, as before, on the two Sundays next preceding the 15th of September. When the revising barrister holds his court, it will be the duty of the overseer to attend. His expenses arising from his duties connected with registration are defrayed from the poor-rate. So far with regard to registration of county voters. Overseers of a parish situated in a borough, by the last day of July, without any claims being made, must make an alphabetical list of persons having a 10*l.* qualification in respect of premises situated in their parish. A similar list of freemen must be made where freemen are entitled to votes. These lists must be fixed as above. Claims from persons omitted and objections are received on or before the 25th of August, and lists of these claims, &c. are to be posted on the two Sundays next preceding the 15th of September. The forms according to which overseers are to frame their notices are to be found in the acts of parliament whence their obligations arise, and are collected in a useful pamphlet, from which this article has been compiled, entitled 'The Duties of Overseers of the Poor,' by George Dudgeon, London.

OVERTURE (*Ouverture*, Fr.), a musical composition for a full instrumental band, introductory to an oratorio, opera, or ballet; a kind of musical prologue, and, as such, ought to be in good keeping with the piece which it ushers in; though in most instances but little attention has been paid to the character of this important feature of the melodrama. There are some exceptions however, and it would be unjust to the memory of three most intellectual composers not to mention, as instances of deep thought and poetical imagination, the fine overtures to *Don Giovanni*, *The Freischutz*, and *A Midsummer-Night's Dream*, all of which fully prepare the mind—in so far as inarticulate sounds can prepare it—for the romantic stories and su-preternatural agency on which the following scenes are founded.

The overture originated with Lully [Lulli], whose compositions supplied many of the early Italian operas with an opening instrumental piece. And indeed the great Handel himself imitated to a certain extent the overtures of the French composer; though in this case, as in every other of the kind, he improved whatever he touched.

OVERYSSEL, a province of the kingdom of the Netherlands, is situated between 52° 6' and 52° 52' N. lat., and between 5° 50' and 7° 5' E. long. The area is 1250 square miles, or about that of the county of Glamorganshire. It is bounded on the north by Friesland and Drenthe, on the east by the kingdom of Hanover and the Prussian province of Westphalia, on the south by Guelderland, and on the west by Guelderland and the Zuyder Zee. It is a low level country, containing a few hills, which the inhabitants call mountains. The soil is wet and marshy, especially in the western part, where the peat moors of Eelaer and Hardenberg extend between Ryssen, Hardenberg, and Ootmarsum. There are likewise several sandy heaths, but near the Yssel there is some rich corn land. The chief river is the Yssel, which runs along the frontier of Guelderland, and is 300 feet in breadth; it is joined at Deventer by the Schipbeek, and falls into the Zuyder Zee below Kampen; other rivers are the Zwarte Water (i.e. Blackwater), the Vechte, and the Linde. A canal, called the Willemsvaart, which unites the Yssel and the Zwarte Water, was opened in 1819. The province contains several small lakes. The climate is moist, and, on account of the extensive marshes, unhealthy. The products are some corn, flax, rapeseed, pulse, potatoes, garden fruits, plums in great abundance, and some wood, especially oak and alder. There are the common domestic animals, poultry, small game, great numbers of wild geese, fish, and bees. The inhabitants derive their chief subsistence from the breeding of cattle and by digging peat. Agriculture is of secondary importance, except in some few spots on the Yssel. The pastures being very rich, especially in the western parts of the province, the cattle attain a great size. The sheep, which are numerous, are of a small breed, and their wool is coarse. The breed has however been improved by the introduction of merinos. The horses are nearly equal to those of Guelderland. Considerable profit is derived from the breeding of bees and the fisheries. The manufactures are linen, woollens, cotton, (especially printing paper and common writing-paper); there are iron-works at Deventer. The bleaching of linen is pretty extensively carried on. The articles of exportation are cattle, butter, cheese, wool, plums, honey, wax, linen, basket-work, oak bark, and paper. In proportion to its extent, this is the least populous province in the kingdom; the number of the inhabitants is 161,166, who are mostly Calvinists; there are however many Roman Catholics, some Baptists, and a few Lutherans.

The province is divided into three districts, those of Zwoll, Almelo, and Deventer, so named after the chief towns. Zwoll, the capital of the province, is a well built town on the Zwarte Water, a short league from the Yssel, and rather farther from the Vechte, with which it has a communication by means of the Willemsvaart above mentioned. It is defended by a rampart, which is planted with rows of trees, and by very strong outworks. It has three gates, leading to as many suburbs, eight churches, a house of correction, and a Latin school. The inhabitants, between 14,000 and 15,000, carry on a considerable trade. There are numerous tanneries, fourteen manufactories of cordage, two paper-manufactories, one of snuff and tobacco, and extensive bleaching-grounds.

Deventer is on the right bank of the Yssel, over which there is a bridge of boats, and which here receives the Schipbeek, which runs through the town. It is a fortified town, but the works have fallen into decay. There are seven churches, the principal of which has some fine paintings on glass. There is a gymnasium and other public institutions. The manufactures are linen, carpets, and stockings, of which the poorhouse supplies 20,000 pairs annually; tobacco, and cordage; many of the inhabitants follow the occupations of tanners, sugar-refiners, salt-boilers, soap-boilers, iron-founders, and brewers. Deventer is famous for a kind of gingerbread, the composition of which is said to be a secret, and which is annually exported to the value of [illegible]. The trade of Deventer is very considerable. The exports are corn of all kinds, linen and bacon, tobacco, wine, cheese (a million pounds in a year), oil, sugar, chicory, as a substitute for coffee, wool, vinegar, and rum. The population is now (1840) above 14,000. Deventer is the birth-place of the learned James Gronovius. Thomas à Kempis taught and died in this town.'

Almelo, on the Vechte, has 2400 inhabitants, among whom there are many Baptists; they manufacture woollens and linen; of the latter 14,000 pieces are annually exported. Other towns in this province are Enschede, 2500 inhabitants, and its district Lonneker, with 6000 inhabitants; the manufactures of which are worth a million of florins annually. Hasselt, 1500 inhabitants; Steenwyck, 2300 inhabitants; Borne, 3200 inhabitants, and Hengelo, 2500 inhabitants, both of them flourishing manufacturing towns. (Hassel; Hörschelmann; Cannabich.)

OVIBOS. [Ox.]

OVIDIUS, PUBLIUS NASO, was born at Sulmo in the country of the Peligni, B.C. 43, the same year in which Cicero was murdered, and on the very day on which the consuls Hirtius and Pansa died. The events of his life are chiefly known from his own writings, and more particularly from the 10th elegy of the 4th book of the 'Tristia.' Ovid was of an equestrian family. He had a brother exactly twelve months older than himself; the two brothers were sent to Rome for their education at an early age. From his boyhood Ovid was fond of writing verses, and, as he says of himself,

'Sponte sua carmen numeros veniebat ad aptos,
Et quod tentabam scribere versus erat.'

His father discouraged his poetic aspirations on the ground that poverty was the condition of poets, and the youth accordingly tried to prepare himself for the career of the bar. The two brothers were educated under the care of some of the best teachers then in Rome—Plotius Gryphus, whom Quintilian (*Inst. Or.*, ii. 4) considered one of the first teachers of eloquence, Arellius Fuscus, the friend of Horace, Messala, and Porcius Latro, the friend and companion of Seneca. Seneca says that he had seen Ovid practising declamation before Fuscus. His brother Lucius died after completing his twentieth year, an event which Ovid most affectionately lamented. On attaining the suitable age, Ovid discharged the office of one of the Triumviri, and other public duties subsequently. He also acted as one of the court of the Centumviri, and on several occasions as a judex. (*Trist.*, ii.) But neither his bodily strength nor his disposition was suited to public or active life; poetry was his delight, and he resolved to dedicate himself to it. He accordingly sought the society of the contemporary poets whose names he has himself recorded. He was acquainted with Macer, Propertius, Ponticus, Bassus, and Horace, who was about twenty-two years older. He only just saw Virgil and Tibullus, both of whom died B.C. 19. He was married to his first wife when he was very young. The match was not a suitable one, and the wife was soon divorced. A second wife was in like manner put away, though the poet had no serious charge to make against her. Ovid's amours with Corinna, whom he celebrates under that fictitious name, and with other women, may have tended to interrupt his conjugal felicity. However this may be, he ventured to take a third wife, with whom he lived happily to the time of his exile. He had a daughter, probably by his third wife; the daughter was twice married. His father died at the advanced age of ninety, and his mother shortly after; but neither of them lived to see their son's disgrace and exile.

Ovid spent an easy life at Rome in the enjoyment of the society of his contemporary poets and friends, Atticus, Pedo Albinovanus, Tuticanus, and others already enumerated, and in the possession of a competent income. He visited Asia and Sicily, but it does not appear at what period of his life (*Ex Pont.*, ii., Ep. 10); probably when he was a young man. His residence at Rome was near the Capitol (*Trist.*, i., El. 3), and he had some gardens near the junction of the Flaminian and Claudian roads; he had also a patrimony in the country of the Peligni. Ovid was intimately acquainted with the family of Augustus Cæsar; and an 'Epicedion on the death of Drusus' (B.C. 9), addressed to his mother Livia, which is still extant, is attributed to him. Among his various poetical works which were written and published before his exile, his three books 'Artis Amatoriæ,' appeared in the year 2 B.C., the same year in which Augustus banished his daughter Julia. Previous to the 'Ars Amatoria' he had published his three books of 'Amores,' which were originally in five books; and also his 'Heroides.'

At the close of the year A.D. 8, when he had just completed his fiftieth year, he was banished from Rome by Augustus. The sentence was altogether unexpected; it fell on the astonished poet like a thunderbolt. The place of his exile was Tomi, a Milesian colony (*Trist.*, iii., El. 9) in the country of the Getæ, on the banks of the Euxine. Ovid has described in a most touching manner (*Trist.*, i., El. 3) the last night which he spent in Rome, and his eternal separation from his wife and friends; his daughter was absent in Libya. His property was not confiscated, but his exile was for life. The cause of the banishment of Ovid is not distinctly stated by himself, nor by any other writer; a circumstance which has led to various conjectures, all of which however are devoid of any historical foundation. The supposition that Ovid was banished for an amour with the emperor's daughter Julia rests on no evidence, and is inconsistent with the fact that Julia was banished ten years before Ovid. He admits (*Trist.*, v., El. 11) that his offence deserved a severer punishment than the emperor inflicted. His sentence was not Exsilium, but Relegatio; and the difference was not unimportant. Exsilium was followed by loss of fortune and citizenship; Relegatio was not followed by loss of citizenship, and only accompanied with loss of property so far as such loss was comprehended in the sentence of Relegatio. The poet himself has expressed this with strict technical accuracy in one of his elegies addressed to his wife, in which he tells her that she cannot be truly upbraided as being the wife of an exile, inasmuch as his sentence was only Relegatio:

> 'Nec vitam, nec opes, nec jus mihi civis ademit;
> Qui merui vitio perdere cuncta meo.
> Sed quia peccato facinus non affuit illi,
> Nil nisi me patriis jussit abire focis.'
> *Trist.*, v., El. 11.

In other passages however (*Trist.*, iii., El. 3, &c.) he calls himself Exsul, but doubtless in the general sense of that term; for Relegatio was one of the species of which Exsilium was the genus.

He admits (*Trist.*, ii. 207) that there were two charges against him, the character of his amatory verses and some fault (error) which he never mentions. The whole of the second book of the 'Tristia,' which is addressed to Augustus, is an apology for his erotic poetry, and he complains that though written long before the date of his banishment, it was made the ground or pretext of his punishment:

> 'Nos quoque jam pridem scripto peccavimus uno:
> Supplicium patitur non nova culpa novum.'
> *Trist.*, ii. 539.

In various other passages (*Trist.*, iii., El. 14; iv., El. 1; v., El. 1; 'Ep. ex Ponto,' i. 1, &c.) he refers to his poetry as one cause of his misfortunes. It may be conjectured that he was punished under the provisions of the Julian Law, De Adulteriis coercendis (*Dig.*, 48, tit. v.), which was passed about B.C. 17; for though the provisions of this law, as known to us, make no mention of obscene poetry, it is clear from the title in the 'Digest' that the law extended beyond punishing the direct parties to an act of adultery, for it punished, among others, those who lent their houses for adulterous purposes. Ovid himself says, that of the two charges brought against him, one should be nameless, but the other was founded on his amatory poetry as encouraging to adultery:

> 'Altera pars superest qua turpi crimine tactus,
> Arguor obsceni doctor adulterii.'
> *Trist.*, ii. 211.

At the time of his banishment the fifteen books of the 'Metamorphoses' were unfinished (*Trist.*, i., El. 1; ii., 555; iii., El. 14); the poet had burned them, as being incomplete, at the time of his leaving Rome, but there were other copies in existence. The twelve books of the 'Fasti,' of which the first six only have been preserved, were also written before his exile, and, as the poet tells us, inscribed to Augustus Cæsar. They were finished during his exile, and, as we now have them, inscribed to Cæsar Germanicus.

The works of Ovid written during his banishment are, the five books of the 'Tristia,' and the four books of his 'Letters from Pontus:' the letters are addressed to his wife, to Maximus, Pedo Albinovanus, Græcinus, Rufinus, and others of his friends. The 'Ibis' also was written in his banishment, and apparently soon after his arrival at Tomi.

Notwithstanding the most abject entreaties of the poet and the interest of his friends, Augustus never recalled him from banishment. He died at Tomi, A.D. 18, in the sixtieth year of his age and the tenth of his banishment. Augustus died four years before him. The circumstance of his not being recalled by Tiberius renders it probable, as has been conjectured, that he had incurred the anger of Livia Augusta. The poet, who had enjoyed all the pleasures of a luxurious capital and the society of all his most distinguished contemporaries, spent the last years of his life among a barbarous people and in an inhospitable climate, worn out with grief and mental anxiety (*Ex Ponto*, i., Ep. 4). His only consolation in exile was to address his wife and absent friends, and his letters were all poetical. The Muses, who were the cause of his calamity, were also his consolation in misfortune. Though the 'Tristia' and the 'Letters from Pontus' have no other topic than the poet's sorrows, his exquisite taste and fruitful invention have redeemed them from the imputation of being tedious, and they are read with pleasure and even with sympathy.

It shows the versatility of his talent that he wrote a poem during his exile in the Getic language; the subject was, the praises of Augustus Cæsar and his family. The rude barbarians to whom Ovid recited this poem were surprised and delighted: their uncivilised minds acknowledged the power of 'immortal verse.' They applauded and anticipated the poet's recall; but the stern master of the Roman world was inexorable. (*Ex Ponto*, iv., Ep. 13.)

The works of Ovid form one of the most valuable parts of the literature of Rome. With the exception of the 'Metamorphoses,' they are all written in the elegiac measure, the restraint of which would have been ill suited to such long compositions as the 'Fasti,' in the hands of almost any other Roman poet. But Ovid was a perfect master of the technical part of poetry, and it is surprising with what consummate skill he has contrived to include in each consecutive pair of verses a full and complete sense. It is rarely necessary to go beyond each pair of verses in order to obtain the meaning of the poet; each couplet is generally complete in itself. And yet the whole of a long poem written in this measure is so artfully and skilfully combined, that it exhibits a faultless unity. It is a necessary consequence however of this restraint, that the elegiac poems of Ovid are sometimes expressed with such an epigrammatic brevity as to be obscure; and the antithesis, which seems to be in some measure inseparable from this kind of measure, and certainly was rather sought after than avoided by the poet, is sometimes too frequent.

If we estimate the character of Ovid by his erotic poetry, we must admit that he is without excuse. The pleasure of the sex seems to have been the uppermost thought of his mind, and the tendency of his 'Amores' and 'Ars Amatoria' must be considered injurious to the morals of a people. The 'Remedia Amoris' can hardly be viewed, as some are inclined to view it, as a kind of Palinodia, or recantation of his amatory poetry. If we estimate the character of the poet by that of the licentious age in which he lived, we shall judge him more favourably: though a man of pleasure, he was temperate in eating and drinking, humane, and generally beloved.

There are no passages in the extant works of Ovid which approach the gross obscenity of many passages in Catullus, Horace, and other Roman writers; and this is a merit, at least viewed as a matter of taste. In a moral point of view his poetry may be more dangerous. The voluptuous pictures of Ovid are only covered with a transparent veil; and even this is sometimes withdrawn. It is rather singular that the 'Heroides,' which abound in obscure allusions and in voluptuous imagery, and are often difficult to understand, should have been so much used as an elementary schoolbook in modern times.

The two great works of Ovid are his 'Metamorphoses' and his 'Fasti.' The subject of the 'Metamorphoses' is briefly expressed in the opening of the first book:—

> 'In nova fert animus mutatas dicere formas
> Corpora. Di cœptis (nam vos mutastis et illas)
> Adspirate meis, primaque ab origine mundi
> Ad mea perpetuum deducite tempora carmen.'

The rich mythology of Greece furnished Ovid, as it may still furnish the poet, the painter, and the sculptor, with materials for his art. With exquisite taste, simplicity, and pathos, he has narrated the fabulous traditions of early ages, and given to them that appearance of reality which only a master hand could impart. His pictures of nature are striking and true; he selects with care that which is appropriate; he rejects the superfluous; and when he has completed his work, it is neither defective nor redundant.

The art of the rhetorician, as well as that of the poet, is perceptible in all the works of Ovid, but particularly in the 'Metamorphoses.' The two speeches of Ajax and Ulysses, in the beginning of the thirteenth book, are in their kind models of oratory. He who could write the speech of Ulysses, might himself have become an orator, and if he had lived in the age of Hortensius and Cicero, might have thriven, as Ulysses did:—

———————— quid facundia posset.

The 'Metamorphoses' are read with pleasure by youth, and are re-read in more advanced age with still greater delight. The poet ventured to predict that his poem would survive him, and be read wherever the Roman name was known.

The '*Fasti*' of Ovid are in fact a valuable historical monument. He has preserved to us the Roman calendar, with all the antient stories attached to it, collected from the traditions of the people and the old chroniclers and antiquaries. His own explanations may often be of little value, but they are easily separated from the antient story or tradition which he relates. He begins with January, and following the days of the month in order, he assigns to each its appropriate festival or solemnities. It shows no small skill in a poet to convert the Calendar of his country into a pleasing and instructive poem, rich in historical facts, and enlivened and relieved by true poetry. A complete commentary on the 'Fasti' would be a valuable commentary on Roman history. The last six books are unfortunately lost.

Ovid wrote also one tragedy at least, the 'Medea' (*Trist.*, ii.) which is highly spoken of by Quintilian (*Inst. Or.*, x. 1), and by Tacitus (*De Orat. Dialog.*, 12).

There are various other small poems attributed to him, perhaps without good reason.

The editions of the collected and separate poems of Ovid are numerous. The best edition of his complete works is by Burmann, 4 vols. 4to., Amsterdam, 1727. The French translations of the various poems, which are very numerous, are mentioned at the end of a long article on Ovid in the 'Biographie Universelle.' There are numerous English translations:—

The best translation of Ovid into English verse is 'Ovid's Metamorphoses, in Fifteen Books, translated by the most Eminent Hands,' London, 1717, fol. There have been numerous reprints of this version. The translators were, Dryden, Addison, Congreve, Rowe, Gay, Ambrose Philips, Garth, Croxall, and Sewell. Sandys translated the first five books, Lond. 1627, fol.; and separate books have been translated by others. There is a literal prose translation by Clarke, London, 1735, 8vo.; and there is another prose translation, London, 1748. There are many translations of the 'Art of Love,' one by Dryden, Congreve, &c., as well as of the 'Heroical Epistles,' one by Quarles, Lond. 1673, 8vo.; and there are translations in verse or prose, or both, of the 'Fasti' and the other works.

It is hardly necessary to remark that a translation of Ovid into English can have little value. A great part of his merit consists in his language; and it is impossible to render the meaning of the original, except by periphrasis and paraphrase, which hardly convey the meaning, and most certainly destroy the beauty of that which is a work of consummate art.

OVIE'DO, a town in Spain and the capital of the province called Asturias, is situated in a plain at the confluence of two little rivers, Ovia or Ove and Nora, the former of which runs into the Nora, and the Nora into the Nalon, another inconsiderable stream in the neighbourhood. The origin of Oviedo is generally assigned to Fruela I., grandson of Pelayo, who is supposed to have built it in A.D. 757, soon after his accession to the throne of Asturias. According to other authorities, Oviedo was a considerable town before the time of that sovereign, who is said only to have made it the capital of his new conquests from the Moors. In either case, it is more than probable that Oviedo was so called from the river Ovia, or Ove, near to which that town stands. During the middle ages Oviedo was known throughout Christendom as the City of the Bishops ('Civitas Episcoporum'), owing, we are told, to the great number of dignitaries of the church who, being persecuted and exiled by the Mohammedan conquerors, took refuge in this place. Oviedo was formerly the seat of a bishop, but a council having been held there in 901, the bishopric was by the Pope converted into an archbishopric. This dignity however was in the course of time transferred to the church of Santiago, and Oviedo became a bishopric as before.

Oviedo contains an episcopal palace, three parishes, a cathedral, and a collegiate church: it had also three convents of monks and three of nuns, besides four hospitals. The university, one of the finest buildings in the town, is well endowed, and contains a numerous and select library. The cathedral, which is also supposed to be the foundation of Fruela in 760, is a magnificent structure of the pure Gothic style, equalled perhaps by none in the Peninsula. It once contained a rich treasury of valuable vases, relics, and other ornaments, but these were almost entirely lost during the French war. The remains of fourteen kings and queens of Asturias are deposited in one of the chapels. There is also in the town another very fine church, San Salvador, built by King Silo in 774. The streets are tolerably straight, regular, and well paved. The principal square, where the market is held, is handsome and large. There are some public walks, ornamented with fountains and trees, the principal being that called 'El Chambul.' The town is provided with good water by a very sumptuous aqueduct of forty-one arches, entirely built of freestone. Oviedo has little or no commerce, like most of the inland towns in Spain, owing to the total want of roads. It has a few tanyards, two manufactories of woollen hats, horn combs, buttons for the use of the peasantry, and some coarse linen-stuffs. There is also a manufacture of arms, supported by the government, but the works have of late been suspended.

The population of Oviedo in 1827, the epoch of the last census, was 10,476. It is the birth-place of the celebrated Feijoo, the author of the 'Teatro Critico,' Madrid, 1777; of the bishop Don Pelayo, who lived in the time of Fernando el Magno, and left a chronicle of Spain and a genealogy of the kings of Asturias; of Luis Fernandez de Oviedo, the author of many excellent works on medicine and botany; and lastly, of the celebrated Marina, the author of the 'Teoria de las Cortes,' Madrid, 1822. Oviedo is 47 miles north of Leon, 43° 19′ N. lat., 5° 57′ W. long.

(Miñano; Florez, *España Sagrada*, Madrid, 1754; Ponz.)

OVIE'DO Y VALDE'S, GONZALO FERNANDEZ DE, one of the earliest historians of the New World, was born at Madrid in 1478. Being of noble Asturian descent, he was, at the age of twelve, introduced into the royal palace as one of the pages of Prince John of Castile, the son of Ferdinand and Isabella. He continued with the court several years, and was present, though a boy, at the closing campaigns of the Moorish war which preceded the surrender of Granada (1490-92). In 1514, according to his own statement, he embarked for the West Indies, where, although he revisited his native country several times, he continued during the remainder of his life. Oviedo occupied several important posts under the government: he was made governor of the fort and harbour of Santo Domingo in the island of Hispaniola or Hayti, and captain of a company of infantry. Charles V. appointed him also to an office of a literary nature, for which he was highly qualified by his vast learning and his long residence in the New World, that of historiographer of the Indies. It was in this capacity that he produced his principal work, 'Historia General de las Indias,' in fifty books, twenty of which, making the first part, were printed for the first time at Seville in 1535, fol.;* reprinted at Salamanca in 1547, fol.; and lastly, at Valladolid in 1557. It was translated into French by Jean Poleur, and published at Paris in 1556, fol. A summary of this work is also inserted in Barcia's collection of the 'Historiadores Primitivos de las Indias Occidentales,' Madrid, 1749, fol. Oviedo wrote likewise 'Tratado de la Natural Historia de las Indias,' Toledo, 1526, besides two tracts respecting the 'Palo de Guayacan' (the Guayacum officinale of Linnæus) and the 'Palo Santo' (Lignum vitæ), which are translated into Latin in the first volume of the collection, 'Scriptorum de Morbo Gallico.' But the work for which Oviedo is justly celebrated, though known only to a few scholars, is his 'Quinquagenas,' so entitled from its consisting of fifty dialogues, in which the author is the chief interlocutor. This interesting production contains a very full notice of the principal persons in Spain, their lineage, revenues, and arms, with an inexhaustible fund of private anecdote, all which renders it a most valuable addition to the history of that time. This work however still remains in manuscript, in three folio volumes, in the national library of Madrid, and it is only through the extracts of Navarrete that we are enabled to estimate its contents. Oviedo has been accused of treating the Indians employed in the gold-mines with unjustifiable cruelty. His 'History of India' too has been denounced by no less an authority than Las Casas as a wholesale fabrication, 'as full of lies almost as pages;' but there can be no doubt that, though somewhat loose and rambling, he possessed extensive stores of information, by which those who have followed him have greatly profited.

---

* A copy of this scarce edition, with the author's signature appended to it, which belonged once to Sir Joseph Banks, is in the British Museum.

The time of Oviedo's death is uncertain, but he must have lived to a considerable age: he was still alive in December, 1556, since the original manuscript above alluded to, preserved in the library at Madrid, is signed by him at the age of 79.

(Navarrete, *Coleccion de Viages y Descubrimientos*, Madrid, 1825 29; Prescott, *History of the Reign of Ferdinand and Isabella*, vol. i.; Muñoz, *Historia del Nuevo Mundo*, Madrid, 1793; Pinelo, *Epitome de la Biblioteca Oriental*, Madrid, 1737.)

OVI'PAROUS. An animal is said to be oviparous when the ovum, or egg, is excluded from the body entire and hatched after such exclusion. Birds and the great majority of reptiles are oviparous animals.

OVIS [SHEEP]

OVOVIVI'PAROUS. An animal is said to be ovoviviparous when the egg is hatched within the body and the young one is excluded alive. Thus, among the *Reptiles*, the young of the Lizard known by the name of *Zootoca vivipara*, the *Viper*, the *Rattlesnake*, and the *Blindworm*, are hatched before they are excluded from the body, and not long before such exclusion: indeed it is probable that the rupture of the egg takes place during the parturition. The Monotremes (*Echidna* and *Ornithorhynchus*) and the *Marsupialia* are examples of ovoviviparous mammiferous quadrupeds.

OVULE, in Botany, is the unimpregnated seed. It originates from a succulent cellular space called the placenta [PLACENTA], in the inside of the seed-vessel, and may be described as a cellular cone or nucleus, enclosed within one or two coats, which are perforated at the apex of the cone. The latter contains a minute sac, called the sac of the amnios, in which the embryo appears after the process of impregnation has taken place. The examination of monstrous formations renders it probable that the ovule, morphologically considered, is a bud; but this doctrine is not universally admitted, and requires confirmation. The modifications of the ovule consist chiefly in an inversion of its parts, and in a loss of one of its membranous coatings, the details of which are suited only to special introductions to botany. An account of them will be found in Lindley's *Introduction to Botany*, 3rd edition, p. 211.

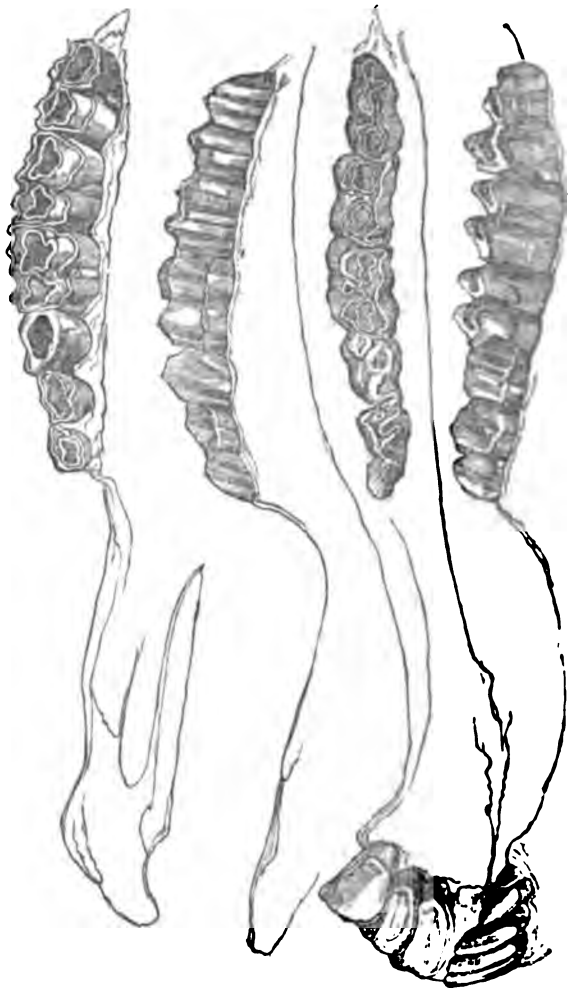
OX. The genus *Bos* of Linnæus consists of those ruminants only which are familiarly known as *Oxen*; and though at the conclusion of this article we shall endeavour to give a sketch of the family *Bovidæ*, according to the views of more modern zoologists, it will treat mainly of *Oxen* only, or the forms comprised under the Linnean genus above named, and the genus *Ovibos* of De Blainville.

ORGANIZATION.

Skeleton; *Skull*.—The front, or forehead, is wide and flattened; the lacrymal bone is enlarged below and leaves no open space between it and the nasal bone. The upper occipital and parietal bones unite at so early a period into a single bone, that the calf almost at its birth has them already in the confluent state; but in the earlier stages of the fœtus, the two parietal and the two interparietal bones are distinguishable. The occipital suture remains strong below the occipital crest, and so differs from the other ruminants; and the frontal suture reaches up to this crest, thus forming the principal character of the physiognomy of the ox. The hole analogous to the sphæno-palatine aperture is enormous and is hidden in the sunken space behind the orbital or supermolar prominence of the maxillary bone; at its superior border a small portion only of the vomer is perceptible. The tympanic cavities terminate in long sharp points, and between them the basilary bone presents two strong prominences. The temporal ala of the anterior sphenoid bone, which in the antelopes and stags has the crest but slightly projecting, has in the Oxen a strong and sharp projection.

Dental Formula:—Incisors $\frac{0}{8}$; canines 0; molars $\frac{6-6}{6-6} = 32$.



Teeth of Ox.

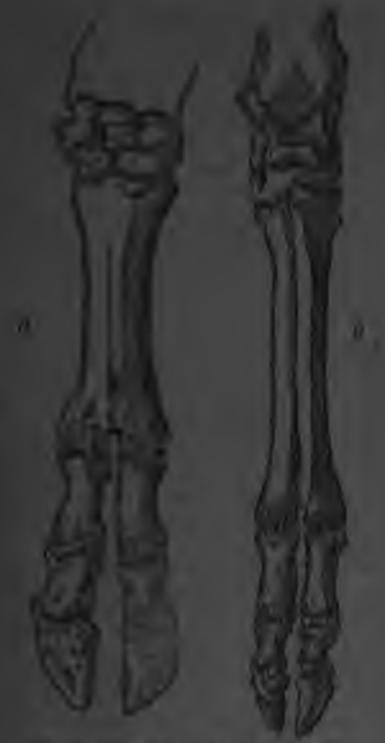
(See the figures of skulls of Oxen in the article BISON* and those of the *Bos Caffer* and *Bos primigenius* below.)

The rest of the skeleton is much like that of the other ruminants, and the following cuts will give a better idea than words of the construction of the extremities.

The anterior angle of the spine of the scapula is prolonged, as in the camels, into an acromial apophysis, and the spinal border is rounded; moreover in the Ox the base of the spine towards the neck of the bone is blended with the anterior border. In the pelvis of the ruminants generally the spinal angle of the ossa ilii is wider and placed more backwards than the external angle, the truncation of which is oblique and nearly continuous to the anterior border of the bone. The pelvis of the Ox may thus be easily distinguished from that of the horse, which has its spinal angle pointed and as forward as the external angle, which last is more truncated, so as to be nearly square. The ischium of the Ox, moreover, is much more elevated above the cotyloid cavity, the ischial tuberosity is truncated so as to present three angles, and the posterior edge of the pelvis

---

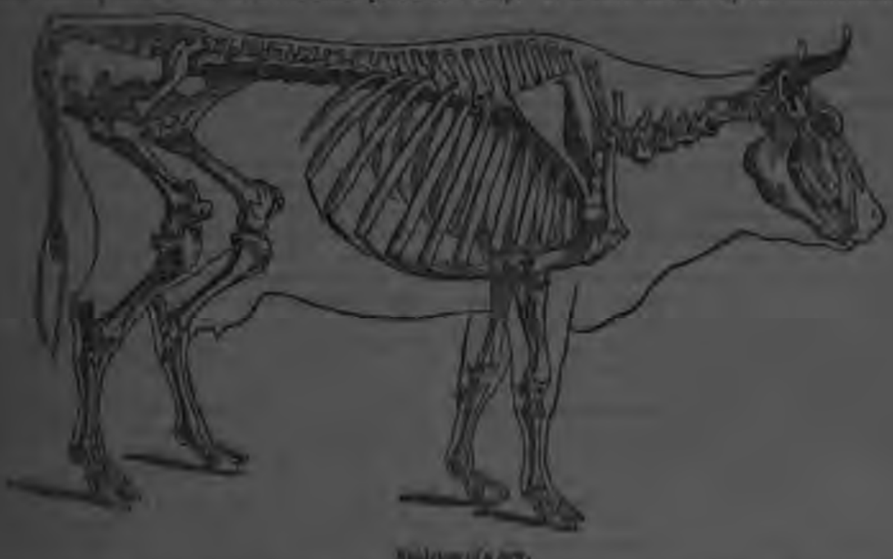
* In the article BISON, vol. iv., p. 462, left hand column, and last line of the third paragraph of the note, for 'anum' read 'unum.'



a, Fore foot of ox; b, hind foot of the same.

forms a well marked re-entering angle, whilst in the horse the same part is nearly rectilinear. Our limits do not permit a more detailed description, and indeed the other points in which the skeleton of the ox differs from other ruminants are principally those of size and proportional length and thickness. The annexed cut will convey a general idea of the entire construction, and the several bones are within the reach of most of those who would wish to examine the parts in detail.

Organs of Digestion.—The number and disposition of the teeth will be found at p. 74; and the digestive canal may be well studied by examining the following preparations in the Museum of the Royal College of Surgeons (*Physiological Series*). No. 555 exhibits the stomach and small intestines of a fœtal calf (*Bos Taurus*, Linn.). The rumen is laid open, showing its communication with the œsophagus and the reticulum, and the several compartments into which it is divided: the two larger occupy the upper part of the paunch; the two smaller form sacculi visible externally at the lower part of the paunch; the latter appear to be analogous to the cardiac sacculi of the Peccary and Kangaroo, but are both lined with cuticle. The reticulum, or honey-comb bag, is laid open, so as to exhibit the large aperture of communication with the preceding cavity, and the groove, or canal, leading from the œsophagus to the psalterium or plicated cavity. It is along this canal that the re-masticated food is conveyed to the psalterium, the muscular walls of the groove shutting out the reticulum equally with the rumen. A black bristle is passed through this communication, and the psalterium laid open, showing the laminæ within it, and the opening into the abomasum, which is left entire. No. 556 consists of portions of the four cavities of the stomach of a calf, exhibiting their manner of communication with each other and with the œsophagus, more especially the canal which leads from the œsophagus to the psalterium, and the muscular sphincter surrounding it. This sphincter is endowed with a peculiar irritability, which occasions it to contract upon the deglutition which follows rumination, and to dilate when food is swallowed after having undergone the first mastication only. It is obvious that by the contraction of this sphincter the re-masticated food is in great measure prevented from entering either the rumen or reticulum, but must pass directly into the third cavity, the orifice of which is by the same act drawn up towards the œsophagus to receive it. The villi of the rumen are very short and pointed. The cells of the reticulum and the laminæ of the psalterium are also beset with villi. The vascular lining of the abomasum is seen to be thrown into broad rugæ, in the small portion of the cavity which is preserved in the preparation. No. 559 is the portion of the rumen of an Ox. The villi are still more flattened in shape than they are in the sheep, and are pointed at the extremity (whereas those in the sheep are dilated), except near the reticulum, where they assume the form of laminæ with irregular jagged margins. No. 560 presents a small portion of the American Bison, in which the villi are much longer, coarser, and of a darker colour. In No. 563, A, a portion of the reticulum of an Ox is shown, where the cells are seen chiefly disposed between broad parallel septa, and the larger cells, formed by the narrower transverse septa, are again divided into smaller cells. No. 564, B, is a small portion of the psalterium of an Ox, prepared to show the different sizes of the laminæ of this cavity. These laminæ are of two kinds, large and small; the larger ones are of two sizes, which alternate with each other; but between each of the larger laminæ a small one is interposed. They are all beset with papillæ, and lined with cuticle, part of which has been turned down from one of the largest laminæ. No. 436, A, is a small portion of the spleen of a calf (*Bos Taurus*), which has been macerated after distension of the cells, to show the meshes of the cavernous structure of the spleen and the large size of the cells or spaces which they intercept. (*Cat.*, vol. i.) It should not be forgotten that the tongue of the Ox performs a principal part in collecting the food before it is submitted to the organs of mastication and digestion.



Skeleton of a cow.

Urinary System.—In the same museum will be found (No. 1222) the kidney of an Ox (*Bos Taurus*) minutely injected, and a section removed to show the ramifications of the pelvis, or elongated infundibula. The cortical substance presents externally a number of clefts extending inwards to a varying depth, and in some degree corresponding to the separate cones of tubuli uriniferi within; this gives a lobulated structure to the gland, which is permanent. A similar structure is observable in the human kidney at an early period of existence, but the clefts are afterwards obliterated by a continued development of the cortical substance. No. 1254 is a similar specimen, and No. 1255 is a smaller lobe of the same kidney, on one side of which the cortical substance is rent, to show the minute tortuous secerning vessels. No. 1256 is the section of the kidney of an Ox, showing three mamillæ converging to terminate apparently in one infundibulum; and No. 1258 exhibits a longitudinal section of the kidney of a bison, showing the numerous medullary cones and the ramifications of the pelvis which extend into the substance of the kidney to surround the mamillæ and receive the urinary secretion. The cortical substance is thinner than in the Ox, and the kidney shorter and broader. (*Cat.*, vol. ii.)

Brain, Nervous System, and Senses.—No. 1328, in the Physiological Series of the same museum, shows the brain of an Ox (*Bos Taurus*) injected, and the pia mater removed from the left hemisphere to show the convolutions, which are more numerous and wavy than in the sheep.

Sight.—This sense is acute in the genus *Bos* by day. The anterior perforation of the choroid coat, or pupil, is oblong. In the Physiological Series of the museum of the College, the broad transverse tapetum lucidum of the eye of an ox is well shown in the preparation No. 1728. The pigmentum in the ox, as well as in most if not all animals feeding on grass, has (in the same eye) certain portions which are white, and others which are of a fine green. The eyelids and nictitating membrane of a cow are exhibited in No. 1785, and bristles are placed in the puncta lachrymalia, and also in the ducts of some of the meibomian glands.

Hearing, also acute.

Smell and Taste.—Well developed. No. 1256 of the series above alluded to shows one of the inferior turbinated bones, with the pituitary membrane injected. The taste is also sufficiently developed, and from the supply of nerves must, in conjunction with the smell, be capable of accurately distinguishing the aroma of various plants in order to the selection of those which are most agreeable and wholesome, and the rejection of those which are disagreeable or noxious to it. That this power of distinction sometimes fails is fatally shown by the mortal consequences of browsing on the yew and other deleterious plants, to which the hungry animals have through carelessness or other accident had access.

Touch.—This sense cannot be very acute in the extreme ends of the extremities at least; though there is sensibility enough to warn the animal of injury and to guide its steps. More would have been superfluous and annoying. In the museum of the Royal College of Surgeons (Physiological Series), No. 256 exhibits the bisulcate foot of a calf injected. The nail or hoof is removed from one of the toes to show the vascular and sensible laminæ, similar to those in the horse, but much smaller. No. 1412 is the foot of a slink calf (*fœtus Vaccæ*) injected, showing the different states of the cuticular covering, which, although still thin and soft where the hoofs are afterwards to be perfected, is too dense at those parts to permit the vascularity of the corium to appear through; and No. 1413 is another foot of a calf injected, and the hoofs removed, to show the vascular laminæ and villi of the corium covering the last phalanges.

Food, Reproduction, &c.—Oxen are eminently herbivorous, for though they will browse upon shrubs and trees, grass and herbage is their staple; no one can watch a cow grazing without observing how perfectly the whole mechanism works together, the tongue sweeping in a whisp of herbage into the vice formed by the cutting-teeth of the lower jaw and the unarmed front of the upper one, and the muscles immediately aiding with the upward jerk to separate the bite from the roots on which it was growing. For an account of the varieties of oxen bred by the grazier, and of the food on which they are fatted for the market, see the article CATTLE. In a state of domesticated nature, that is, where the animal roams at large and is not stall-fed, or confined to what are called artificial grasses, or to artificial food, we are told in 'The Swedish Pan' (*Amœn. Acad.*, vol. ii.) that oxen eat 276 plants and refuse 218; that heifers waste away in enclosures where the *meadow-sweet* grows in abundance and covers the ground so that they can scarce make their way through it: 'the country-people,' says the author, 'are amazed, and imagine that the *meadow-sweet* affords them no nourishment; whereas the goat, which is bleating on the other side of the hedge, is not suffered to go in, though he longs to be browsing on this plant, which to him is delicate and nourishing food.' The leaves of the *Long-leaved Water Hemlock* are fatal to oxen, whilst the goat feeds heartily and safely upon it. Linnæus found that this plant was the cause of the terrible disease that raged among the horned cattle at Tornea. He had scarcely left the boat which carried him over the river to the fatal meadow before he was convinced. The cattle, it appeared, died as soon as they left off their winter fodder and returned to grazing; the disease diminished as the summer came on, at which time, as well as in the autumn, few died. The distemper was propagated irregularly and not by contagion: the cows were driven in the spring to the meadow where Linnæus landed, and where he saw plenty of the *Long-leaved Water Hemlock*, and there they died swollen and in convulsions. In other places the plant was scarce. 'The least attention will convince us,' says Linnæus, 'that brutes spurn whatever is hurtful to them, and distinguish poisonous plants from salutary by natural instinct; so that this plant is not eaten by them in the summer and autumn, which is the reason that in those seasons so few cattle die, viz. only such as either accidentally or pressed by extreme hunger eat of it. But when they are let into the pastures in spring, partly from their greediness after fresh herbs, and partly from the emptiness and hunger which they have undergone during a long winter, they devour every green thing which comes in their way. It happens moreover that herbs at this time are small, and scarcely supply food in sufficient quantity. They are besides more juicy, are covered with water, and smell less strong, so that what is noxious is not easily discerned from what is wholesome. I observed likewise that the radical leaves were always bitten, the others not; which confirms what I have just said. I saw this plant in an adjoining meadow mowed along with grass for winter fodder; and therefore it is not wonderful that some cattle, though but a few, should die of it in winter. After I left Tornea I saw no more of this plant till I came to the vast meadows near Limmingen, where it appeared along the road; and when I got into the town I heard the same complaints as at Tornea, of the annual loss of cattle with the same circumstances.' The author of the 'Swedish Pan' also observes that a hungry stomach will often drive animals to feed upon plants that were not intended for them by nature. But whenever this has happened, they, if they escape, become more cautious for the future, and acquire a certain kind of experience; and he instances the *Monk's-hood*, which grows near Fahluna, and is generally left untouched by all the animals that are accustomed to these places; but if foreign cattle are brought thither and meet with this vegetable, they venture to take too large a quantity of it, and are killed. He adds that the cattle that have been reared in the plains of Schonen and Westragothia commonly fall into a dysentery when they come into the woodland parts, because they feed upon some plants which the cattle used to those places have learned to avoid. *Meadow-Saffron* is among the plants deleterious to oxen if taken in any large quantity; and *Hellebore* is also said to be poisonous to them. *Yew* is fatal, as it is to herbivorous quadrupeds generally, the green temptation being probably too strong for cattle kept on short allowance. Actions-at-law in this country have not been uncommon against a defendant for not keeping up bounds or hedges, whereby the plaintiff's cattle strayed into places where yew-trees grew, fed on the branches, and so died.

Preparations illustrative of the organs of generation in the male will be found in the Physiological Series of the museum of the College, Nos. 2557, 2558, 2559; and Nos. 2756, 2757, 2758, 2759, and 2760, illustrate the female organs, the first of the last-named numbers exhibiting those of the American Bison, and the others those of the Cow (*Bos Taurus*), the Heifer, and the fœtal cow.

The period of gestation is nine months. The normal number is one; though there are not uncommon instances of the cow bringing forth twins, and rare cases of her producing three, and even more, at a birth. In the case of twins, if they be male and female apparently, the apparent female is generally barren, and is called a *Free Martin* (*Taura* probably of Columella, Varro, and the antient Romans).

Mr. Jesse (*Gleanings of Natural History*, 1838) states that if the cow has twins, one of them a male and the other a female: the latter is *always* barren; but this is an error, as we shall presently see. 'It is a fact known, and I believe almost universally understood,' writes John Hunter, in his *Account of the Free-Martin*,* 'that when a cow brings forth two calves, and one of them a bull-calf, and the other to appearance a cow, that the cow-calf is unfit for propagation, but the bull-calf grows up into a very proper bull. Such a cow-calf is called in this country a Free-Martin, and is commonly as well known among the farmers as either cow or bull. Although it will appear from the description of this animal, that it is an hermaphrodite (being in no respect different from other hermaphrodites), yet I shall retain the term *free-martin* to distinguish the hermaphrodite produced in this way from those which resemble the hermaphrodite of other animals; for I know that in black cattle such a deviation may be produced without the circumstance of twins; and even where there are twins, the one a male, the other a female, they may both have the organs of generation perfectly formed.'

Hunter goes on to state that the *Free-Martin* has all the external marks of a cow-calf as to the teats and the external female parts, or *bearing*, as the farmers term it; it shows no inclination for the bull, nor does the bull take notice of it. The form much resembles that of the ox or spayed heifer, and the animal is considerably larger than either the bull or cow, with horns similar to those of the ox. Its bellow is like that of an ox, having more resemblance to that of the cow than the bull, and, like the ox, it is used for the yoke and fattened for the table. The flesh is generally considered finer in fibre than that of either bull or cow, and to surpass that of the ox and heifer in delicacy of flavour, bearing therefore a higher price in the market; but there are not wanting exceptions where the flesh has turned out nearly as bad as bull-beef, certainly worse than that of a cow.

That the twin female is not always barren when the other calf is a male is proved by the following among other instances. Hunter relates that a cow belonging to Benjamin Way, Esq., of Denham, near Uxbridge, produced twins which were to appearance male and female. The latter died when about a month old. Upon examining the organs of generation, Hunter found that they were perfectly formed, and to make certain he procured those of a common cow-calf, and in comparison found them exactly alike. 'This,' he continues, 'made me regret that the animal had not lived to that age that might have determined if it was capable of breeding; for the construction of the parts being to appearance perfect, is not sufficient of itself to stamp it a true or perfect female. . . . . It is however most probable that this was a perfect female, which is an exception to the common rule; and I have been informed there are instances of such twins breeding.' Professor Owen, in his valuable edition of Hunter's 'Observations' (1837), adds a note from Loudon's 'Magazine of Natural History,' which states that Joseph Holroyd, Esq., of Wilbers, near Leeds, had a cow which calved twins, a bull-calf and a cow-calf. As popular opinion was against the cow-calf breeding, it being considered a free-martin, Mr. Holroyd was determined to make an experiment of them, and reared them together. They copulated, and in due time the heifer brought forth a bull-calf, and she regularly had calves for six or seven years afterwards. Nor are there wanting other cases of fertility under similar circumstances.

Hunter gives a dissection of three free-martins, a portrait of one, and figures of the organs of generation of all three, in the work last above mentioned, to which we refer the reader for farther particulars.

When a cow has twins and they are both bull-calves, the calves are in every respect perfect bulls; and if cow-calves, they are both perfect cows. At least we are not aware of any recorded instance to the contrary, nor have we ever heard of any.

In the 'Nouveau Bulletin des Sciences' is given an account of a cow which produced nine calves at three successive births: first, four cow-calves, in 1817; second, three, two of them females, in 1818; third, two females, in 1819. With the exception of two belonging to the first birth, all were reared by the mother.

EUROPEAN OXEN.

In addition to what is stated with regard to the supposed origin of our British domestic horned cattle in the article Bos-Urus (vol. v., p. 231, et seq.), we proceed to the consideration of the further opinions published on this difficult subject.

Colonel Hamilton Smith, who appears to have taken considerable pains in investigating the history of the *Ruminantia* generally, and of the Bovine family particularly, places the fossil species under *Bos (Taurus) Urus*, considering the wild cattle of Chillingham and other parks as the white variety.

Mr. Swainson (*Classification of Quadrupeds*) observes that all writers agree that the large skulls of oxen found in the more recent formations belonged to a formidable race of these animals which existed in Britain in a wild state; that they belonged without doubt to the species named *Urus* by Cæsar and other antient writers; and that these skulls not only possess a specific distinction, but exhibit the type of a form essentially different from that of the domestic ox. 'All these skulls,' he continues, 'are nearly one-third larger than those of the *Bos Taurus*; they are square from the orbits to the occipital crest, and somewhat hollow at the forehead. The horns, placed at the side of the above crest, show a peculiar rise from their roots upwards; then bending outwards, and then forwards and inwards. No domestic races show this turn; but numerous specimens of inferior sizes, found fossil in the Cornish mines, have this shape, and the wild bull of Scotland, the only example of this type now known to exist, retains it. The domestic oxen, on the contrary, of whatsoever country or breed they may be, have the square concave forehead, with the horns rising from the ends of the frontal ridge. . . . It appears then that the antient *Urus*, or wild bull, was a perfectly wild, savage, and untameable animal; not only does every account handed down from remote antiquity assure us of this, but it is even verified by the only living example of this *form* we possess, the *Bos Scoticus*, still preserved in one or two of the northern parks. Although domesticated so far as to live within such precincts without absolute unprovoked violence to its keepers, it retains essentially all the savage characters ascribed to the more powerful species mentioned by the antients. Like that also it possesses, when at a mature age, a kind of mane, about two inches long, and its throat and breast are covered with coarse hair. These characters, which are never found in the domesticated breeds of oxen, were no doubt much more highly developed in the antient *Urus*. The second type is the domestic ox; the external characters of which, to use the words of Major (Colonel) Smith, are "absolutely the same as the fossil *Urus*, and the wild breeds differ only in the flexure of the horns." But though these two types come so near each other in external appearance, nothing can be more different than their moral character; the *Urus*, wild, savage, and untameable, remains, with all these propensities unimpaired and undiminished, from the period of its first creation down to the present day. The other, tame, harmless, and enduring, has voluntarily submitted to the service of man from the most remote antiquity, and seems to have been a companion of the earliest inhabitants of the earth.' Thus far Mr. Swainson (1835).

Sir W. Jardine (*Naturalist's Library,—Ruminantia*, part ii., 1836) remarks that by most persons it is thought that the domestic races of our cattle are originally sprung from the *Bos bubalus*, the Indian and European buffalo. 'Some again,' continues Sir William, 'treat of them as arising from the aurochs or wild cattle of Germany and Poland. These, according to the system of Smith, come into a subgenus different from the domestic breeds; and from both these suppositions the opinion of Baron Cuvier varies, as he is inclined to consider our present cattle identical with a species no longer existing in a wild state, but which has, by the exertions of man, as in the instance of the camel and dromedary, been for ages entirely subjected to his power. The remains of this animal have been found in a fossil state, and it is upon the comparison of these remains with the skeleton of the aurochs, the buffalo, and our domestic races, that the Baron has founded his opinion.'

Mr. Bell (*British Quadrupeds*, 1839,—the *Ox*), after referring to Griffith's Cuvier for Colonel Hamilton Smith's interesting and learned dissertation upon the mythology and antient history of the ox, says, 'Whether the ox exist now, or have existed within the range of sound historical testimony, in its original state, or whether, as in the case of the horse, all the instances of the occurrence of wild oxen of this species now on record have not been derived from the domestic race, fortuitously escaped from servitude and become wild, is a question which it is difficult if not impossible satisfactorily to solve. The antient accounts of the Urus, or wild ox, declare it to have been an animal of enormous size and great fierceness; and the horns are described as being large, spreading, and acute. In this country, and in many parts of the Continent, have occurred numerous fossil bones of oxen, with large horns, having the form and direction of those of certain breeds only of our present cattle, particularly of such as are most wild; as for instance the celebrated wild white oxen of Craven, of Chillingham Park, and of Scotland, the *Bos Scoticus* of some authors. I cannot but consider it as extremely probable that these fossil remains belonged to the original wild condition of our domestic ox, an opinion which Cuvier appears to have entertained, who calls the skulls "Crânes semblables à ceux d'un bœuf domestique." They are found only in very recent deposits, frequently in caverns mingled with the remains of various other animals, as in the celebrated cave of Kirkdale, and in different parts of Cornwall and of Devonshire. I have several teeth and some fragments of bones from Kent's Hole, in the latter county, where they were found in the same mass with the remains of the elephant, the rhinoceros, the deer, the bear, and the hyæna. Cuvier however considers that they existed after the destruction of the latter species. It has indeed been attempted to prove that the antient remains alluded to, together with the Chillingham and Scottish breed, belong to a distinct specific type from the common domestic ox; and some modifications of structure have been cited in proof of this opinion. It does not appear to me however that these modifications are of sufficient value to constitute specific distinction, as they appertain only to parts which are very variable in particular breeds of the domestic cattle; they are, some slight differences in the form and direction of the horns, and the existence, in *old Bulls*, of a short rudimentary mane, and some hair upon the breast. Now there is certainly no point of sufficient importance to form a specific distinction, even were the form of the horns less variable than they are in our domestic oxen. We require yet a series of well authenticated and well directed experiments on the intermixture of the Scottish or Chillingham cattle with the domestic breeds, and the fertile or infertile character of the progeny; which, if the views I have so repeatedly stated be correct, would at once decide the question. Even Colonel Smith himself, a high authority in these matters, although he urges the specific distinction of the two animals, says, "the character of the domestic oxen is absolutely the same as the fossil, and the wild breeds differ only in the flexure of the horns and external appearance, occasioned by the variations of climate, food, and treatment." But, it may be asked, do variations of climate, food, and treatment produce specific distinctions? And yet this distinction is, as I have just stated, held both by Col. Smith and Mr. Swainson. Upon the whole, I cannot but believe that the fossil bones belonged to the original stock of our domestic ox, and that the wild white cattle, the *Bos Scoticus* and *Urus Scoticus* of the authors just named, approach so near to it as to leave it a matter of doubt, *not* whether they all belong to the same species, but whether this breed be the actual remnant of that original stock, or the descendants of domesticated individuals, which have resumed in a great degree their wild character from having ceased through many generations to feel the effects of human domination.'

Mr. Henry Woods, in his *Description of the fossil Skull of an Ox (Bos Primigenius), discovered in May*, 1838, *at Melksham, Wilts.* 4to., 1839, after premising with reference to this part of the inquiry, that unfortunately two distinct species of Bos have received the title of *Urus*, states that the subject appears to him to stand thus: 'The *Urus* of the antients, *Bos Taurus*, Linn., is the ordinary wild bull of Central and Northern Europe, in some parts of which it is said to exist at the present day, particularly in Lithuania, Poland, &c., which is however somewhat more than doubtful; this is the true *Urus* (most probably a very old corruption of *Taurus*) of Cæsar, in whose time a remnant of the race seems to have existed—the *aurochs* of *antient* Germany, and the typical species to which the remains here described are to be referred.

'The *Bubalus* of Cæsar, bison of the antients, *Bos bison*, Linn., *Bos Urus*, Bodd., is the true auroch or bison of the modern Germans; and there is no doubt but that, as remarked by Cuvier, all the error and uncertainty as to the identity and separation of these species have arisen from the former having become extinct, or merged entirely into the state of domestication, and its original title having been transferred to the latter—an animal very similar in size, figure, and habits, and now existing in a wild state in the districts formerly inhabited by the *Urus* or common ox:—these are principally Poland, where it is termed the *Subr* or *Zubr*; the forests of Southern Russia; and the Carpathian and Caucasian mountains.'

We must not omit the opinion of Bojanus, who (*Nova Acta Academiæ Naturæ Curiosorum*), as long ago as 1826-7, after reviewing those advanced by Cuvier and others concerning the *Urus* or *Bison* of Eastern Europe, and the fossil remains of the different races of the Bovine genus, and giving a detailed account of the habits and structure, and more particularly of the bony skeleton, of the celebrated breed, which is at present restricted to Lithuania, containing about six hundred head, was decided in coming to the conclusion that the *Urus* and *Bison* of the Greeks and Romans, and of later European authors, are one and the same animal; and he refers the fossil remains of the genus to two distinct types; the one which he denominates *Urus priscus*; and the other, the *Bos primigenius*, approximating, but in a less degree, to the domestic ox.

It now becomes necessary to turn our attention to the British wild cattle still in existence, and so often referred to in the course of every argument touching the origin of our domestic oxen. These wild cattle are stated by Lesley to have inhabited the great Caledonian Forest in antient times, and more recently they were to be found in Chillingham Park, Hamilton, Wollaton, Gisburne in Craven, Lime-hall in Cheshire, Chartley Park, &c. In the first-named of these localities they are carefully preserved in their pristine purity, and we select the description of these in Bewick (Mr. Culley's, we believe) as being of older date than some of the interesting accounts lately published, and to which we shall presently advert. 'Their colour is invariably of a creamy white, muzzle black; the whole of the inside of the ear, and about one-third of the outside, from the tips downwards, red; horns white with black tips, very fine and bent upwards; some of the bulls have a thin upright mane, about an inch and a half or two inches long. At the first appearance of any person they set off in full gallop, and at the distance of two or three hundred yards make a wheel round, and come boldly up again, tossing their heads in a menacing manner: on a sudden they make a full stop, at the distance of forty or fifty yards, looking wildly at the object of their surprise; but upon the least motion being made, they all again turn round and fly off with equal speed, but not to the same distance: forming a shorter circle, and again returning with a bolder and more threatening aspect than before, they approach much nearer, probably within thirty yards, when they make another stand, and again fly off; this they do several times, shortening their distance, and advancing nearer, till they come within ten yards; when most people think it prudent to leave them, not choosing to provoke them further; for there is little doubt but, in two or three turns more, they would make an attack. The mode of killing them was perhaps the only modern remains of the grandeur of antient hunting. On notice being given that a wild bull would be killed on a certain day, the inhabitants of the neighbourhood came armed with guns, &c., sometimes to the amount of a hundred horse, and four or five hundred foot, who stood upon walls, or got into trees, while the horsemen rode off the bull from the rest of the herd, until he stood at bay, when a marksman dismounted and shot. At some of these huntings, twenty or thirty shots have been fired before he was subdued. On such occasions the bleeding victim grew desperately furious from the smarting of his wounds and the shouts of savage joy that were echoing from every side: but from the number of accidents that happened, this dangerous mode has been little practised of late years; the park-keeper alone generally shooting them with a rifled gun at one shot. When the cows calve, they hide their calves for a week or ten days in some sequestered situation, and go and suckle them two or three times a day. If any person come near the calves, they clap their heads close to the ground, and lie like a hare in form to hide themselves: this is a proof of their native wildness, and is corroborated by the following circumstance that happened to the writer of this narrative, who found a hidden calf, two days old, very lean and very weak—on stroking its head, it got up, pawed two or three times like an old bull, bellowed very loud, stepped back a few paces, and bolted at the bait with all its force; it then began to paw again, bellowed, stepped back, and bolted as before; but knowing its intention, and stepping aside, it missed him, fell, and was so very weak that it could not rise, though it made several efforts; but it had done enough; the whole herd were alarmed, and coming to its rescue obliged him to retire; for the dams will allow no person to touch their calves without attacking them with impetuous ferocity. When any one happens to be wounded, or is grown weak and feeble through age or sickness, the rest of the herd set upon it and gore it to death. The weight of the oxen is generally from forty to fifty stones the four quarters; the cows about thirty. The beef is finely marbled and of excellent flavour. Those at Burton Constable in the county of York were all destroyed by a distemper a few years since. They varied slightly from those at Chillingham, having black ears and muzzles, and the tips of their tails of the same colour; they were also much larger, many of them weighing sixty stones; probably owing to the richness of the pasturage in Holderness, but generally attributed to the difference of kind between those with black and with red ears, the former of which they studiously endeavour to preserve. The breed which was at Drumlanrig in Scotland had also black ears.'

Now though there is unquestionably in this interesting account ample evidence of wild habits, there is nothing to be found in it to show that the race had not been at some time under the dominion of man, and from circumstances had been for a series of years liberated from his yoke. The prevailing white colour is not usually found in mammiferous races which have never been domesticated;* and with regard to the red ears, Mr. Bell twice admits the probability of the pure creamy white body, the red ears, and the black muzzle being a true specific character; since (he says) he has been in the habit, ever since he was a boy, of examining every white specimen of cattle that has come within his observation, and he has never yet seen one that had not some colour about the ears, either red or black, according to the breed. His attention was first attracted to this by having, when a schoolboy, seen a beautiful pure white calf, belonging to the parent of one of his schoolfellows, and, finding that about half of the ears was red, it struck him that such might possibly be an invariable character, and so, he says, he has found it.

With regard to the test of breeding proposed by Mr. Bell, it is stated in a note to the narrative quoted above from Bewick, that tame cows in season are frequently turned out amongst the wild cattle at Chillingham and admit the bull; and that the calves produced by these means are invariably of the same colour with the wild breed (white with red ears) and retain a good deal of the fierceness of their sire. In Sir William Jardine's volume above alluded to, the weight of the Chillingham cattle is said to reach from fifty to sixty stones, and the oxen are stated to feed kindly, approaching near to the Lancashire breed, the horns being long and beautifully turned. 'A few years ago, a fine ox was fed to a large size, and was quite tame and gentle.' The turning out of tame cows, mentioned in Bewick, is, it seems, no longer permitted, for the present keeper at the park (1836) at one time possessed a wild cow, which he had taken when a calf, in consequence of the death of its mother; it was gentle, was milked as a cow, and bred freely with the common bull; but the propagation was not allowed to proceed farther, the calves being killed at an early age; at Hamilton also great care is taken to preserve the breed, and if a cross should take place with the domestic bull, the young is destroyed. (Jardine.) We can understand the pardonable pride of keeping up this fine ancient breed of cattle in all its purity;† but we must nevertheless regret that the experiment had not been allowed to proceed so as to afford the test alluded to by Mr. Bell.

But though these wild cattle have for a long period been looked upon by many as the descendants of the aboriginal race of Oxen in Great Britain, serious doubts, supported by reasoning of some strength, have been entertained of their claim to such high antiquity.

The author of the article *Bos*, in the 'British Cyclopædia,' is of opinion that they are not descended from the aboriginal stock, but that they are domesticated oxen which have run wild, and that the race was originally imported by the ecclesiastics from Italy, where herds of wild cattle much resembling them still exist. The Gisburne wild oxen* are said to have been originally brought from Whalley Abbey in Lancashire, upon the dissolution of that monastery in the time of Henry VIII. Sir William Jardine gives a very interesting account of the Hamilton herd by Robert Browne, Esq., chamberlain to the duke. 'These cattle are larger and more robust than Lord Tankerville's; their body is dun white; the inside of the ears, the muzzle, and the hoofs black; and the fore part of the leg, from the knee downwards, mottled with black. The cows seldom have horns. Their heads are rounder than in the Tankerville breed. The roof of the mouth is black, or spotted with black, and the tongue is black, and generally tipped with black.' Mr. Hindmarsh's paper read to the British Association in 1838, gives a history of the principal herd at Chillingham, and a graphic description by Lord Tankerville himself. Sir Philip Egerton ('Annals of Nat. Hist.,' 1839) states, on the authority of a MS. record, that the same breed of wild cattle existed at Bishop's Auckland in 1635. Mr. Woods thinks that there appears considerable doubt as to their being truly descendants of a native race, and quotes Lord Tankerville's letter. 'In the first place,' says his lordship, 'I must premise that our information as to their origin is very scanty; all that we know and believe in respect to it rests on conjecture, supported however by certain facts and reasonings, which lead us to believe in their antient origin, not so much from any direct evidence, as from the improbability of any hypothesis ascribing to them a more recent date.'

It is dangerous to prophesy; but we venture to believe that, if a cross with the common bull were to be permitted, the offspring would be as fertile as any of the varieties which now adorn the pastures of Great Britain and Ireland.

The most accurate representation of the Chillingham breed known to us, with the exception of Edwin Landseer's, is 'The Wild Bull of the Antient Caledonian Breed, now in the Park at Chillingham Castle, Northumberland,' designed and engraved by Thomas Bewick, and printed at Newcastle by Solomon Hodgson, in 1789. The size of the cut was 9¾ inches by 7½ inches, and only 230 copies were printed. It was the largest wood-cut that Thomas Bewick ever engraved, and is justly celebrated as his masterpiece. After the few impressions were taken, the block broke into several pieces; these pieces were bound together with iron, with the exception of the figured border, which was about three-quarters of an inch in breadth, cut upon several pieces of wood, and put round the block; and in 1817, impressions were printed by Edward Walker, Newcastle, without the border; the size of the cut being then reduced to 7¾ inches by 5½ inches. About six proof impressions were taken off on vellum from the block in its original state, and are highly valued. (*Memoir, Select Fables*, 1820.) The figure of the Wild Bull in Bewick's 'Quadrupeds' is tame in comparison.

We now proceed to consider the Ox in an economical point of view.

Ox or *Steer* is the castrated male of the bovine race: he is called an *ox-calf* or *bull-calf* until he is a twelvemonth old, a *steer* until he is four years old, and after that an *ox* or *bullock*. A sufficient number of the most likely of the male calves being selected for the future propagation of the breed, the others are castrated between the first and third months.

The advantages derived from the performance of this operation are very great. The nutriment, which is no longer directed to the sexual organs, goes to the general enlargement of the frame; the propensity to fatten is abundantly increased, and the animal becomes far more docile and tractable. The use of the ox in agricultural and other labours may be traced in almost every country and to periods of the remotest antiquity.

The education of the steer should commence between the second and third year. At an earlier period he has scarcely sufficient strength, and at a later one he may have become obstinate and self willed. His education should be founded on patience and kindness, and then the term of it will be far shorter than is generally imagined, and the result will be permanent.

---

* The White Bear is certainly an exception to the [illegible]; but it may be [illegible] as an exception to the [illegible]; the same in the Alpine [illegible]

† [illegible]

* White, like the Chillingham cattle, but hornless, and without the inside of the ears [illegible].

There has been much dispute with regard to the comparative advantage of the employment of cattle and horses in agricultural labours. The former are said to cost less and to be supported at less expense. For the latter it is pleaded that a smaller number are needed—that the work is, on pressing occasions, far more quickly performed, and that it is always abundantly greater. The plain matter of fact however is, that although the ox is still used for slow and heavy work on many farms, he is not so generally employed as he used to be, even by his warmest advocates, and the use of him has been completely abandoned by a very considerable number of agriculturists.

In the native counties of the best breeds, he is still admired and valued as a beast of draught, but by the majority of farmers his value is now chiefly or solely estimated by the quantity and quality of the meat that he will yield, according to the care that is bestowed upon him and the expense that is incurred. He is in the fullest perfection at four years old, and he will then prove more profitable to the farmer than if he were worked four or five years longer, when the quality of his flesh will be deteriorated and his disposition to fatten considerably impaired.

The consideration of the principal *diseases* of cattle was purposely deferred until their different breeds and varieties and uses had passed under consideration. They are not so numerous as those of the horse, but there is often considerable difficulty attending the treatment of them. From the peculiar temperament of cattle and the comparatively great quantity of blood which flows in their veins, promptness in the recognition and the treatment of disease is of far greater consequence than in the horse, rapid as is often the progress of his maladies. Few of the diseases of the horse destroy him at once; but there are many maladies of the ox which must be met at the instant, or they will be uselessly struggled with afterwards. Let the owner and the veterinary surgeon take good heed of this.

The *diseases of calves* should be first considered. They are as numerous as those of the colt, and more fatal. At the head of them stands *diarrhœa*. This sometimes occurs when the calf is suffered to continue by the side of its own dam. Both starvation and excess of food in the mother will produce it. More particularly will this be the case when a foster-mother is employed. If she has calved but a very few weeks before the newly-dropped young one is put to her, the bowels of the calf will almost certainly be disturbed. Where it can conveniently be accomplished, every calf should be reared by its own dam. A state of considerable purging should never be neglected many days, and more especially if the animal loses its gaiety or is in evident pain, or the dung is unusually offensive or tinged with blood. The grand cause of this is acidity in the stomach or intestines, which gradually causes inflammation of the inner coat of these vessels. The irritation here set up is communicated to the constitution generally, and exhaustion and death ensue. Then recourse must be had to a compound medicine, the value of which cannot be too highly estimated. It is borrowed from the work on 'Cattle,' published by the Society for the Diffusion of Useful Knowledge, and the farmer should never be without it. There should be an alkali, chalk, to neutralise the acid; an astringent, catechu, to arrest the discharge; a sedative, opium, to allay the irritation; and a carminative, ginger, to support the strength of the patient. These should be mingled in the proportions of eight parts of the first, four of the second, one of the third, and two of the fourth. A large teaspoonful of this powder should be given twice or thrice in the day, according to circumstances.

Costiveness is a contrary disease to this. It should never be suffered to continue long, for it is fraught with danger. The best aperient for calves and cattle is Epsom salts, in doses of from one to two ounces, with a scruple or half a drachm of ginger.

Cough should be promptly attended to the moment that it is heard. A dose of physic, small doses of powdered foxglove, with nitre, or, in bad cases, a slight bleeding, will usually remove it.

In proceeding to the diseases of adult cattle, we are struck with the numerous *diseases of the eye*. *Ulceration of the lids* will generally yield to the nitrated ointment of mercury locally applied, and a course of alterative medicine. *Warts* should be excised by means of a pair of scissors, and the root touched with nitrate of silver.

For inflammation of the *haw*, or membrane at the corner of the eye, a weak goulard lotion, or the tincture of opium, lowered with ten times its quantity of water, will be useful; but if there is any fungous growth on the haw, extirpation will afford the only cure. *Inflammation of the eyelids* will generally yield to fomentations of warm water. For *inflammation of the eye*, warm or cold fomentations, the former at the first, and the latter a day or two afterwards, with the opiate lotion at the commencement, and a very diluted one of white vitriol—two grains to the ounce—when the inflammation is subdued, with a moderate bleeding or a dose of physic, will constitute the most successful means of cure. *Ulceration of the eye* will be best treated with the opiate lotion, but *cataract* and *gutta serena* do not admit of cure.

In *fracture of the horn*, if the bones are not quite separated, they may be bound together by tarred cords or splents. If there is a perfect fracture of the bone, it should be sawn off as closely as possible to the head, and a hot iron passed over the surface.

Water in the head in calves, known by the enlargement of the head and the stupidity of the animal, admits not of any cure. The *giddiness* which is sometimes observed in them and even in the adult beasts—turning round and round—is usually hopeless.

Apoplexy, or sudden determination of the blood to the head, produced by the forcing system being carried too far and the process of fattening hurried too rapidly on, can be cured only by the most decisive measures. The animal that is thus *struck* must be bled until he faints, and powerful purgatives administered and continued. *Phrenzy* is produced by the same cause, and can only be cured by the same treatment. In these cases, 15 or 20 drops of the croton oil should be added to the aperient. *Locked-jaw* too frequently bids defiance to medical treatment. The only hope of cure consists in active bleeding and the continued use of Epsom salts and croton oil, until the bowels are opened. Immediately after the bleeding, the jaws will usually be found sufficiently relaxed to admit of the administration of medicine. This golden opportunity should never be lost. As an adjuvant, a seton of black hellebore in the dewlap may be tried. Young cattle are occasionally subject to *fits*. Almost without warning, the beast staggers, falls, bellows, and is convulsed in every limb. This is the consequence of over-heating or over-driving, or both. The physic and the fleam must be here put into active use. Perhaps it would be prudent to send such a patient to the butcher with very little delay.

Rheumatism.—There are few diseases of more frequent occurrence among cattle than this. It is not long absent in a low marshy situation, and it is the constant attendant on careless or cruel exposure to cold and wet. It is recognised by the difficulty of motion and the occasional expression of pain. The cure is comprehended in one word, 'comfort.' A little mild physic, with warm comfortable drinks and gently stimulating applications, will hasten and confirm the cure. Connected with or a consequence of rheumatism is *swelled joints*, yielding sometimes to stimulating embrocations and comfortable lodging. There are however other tumours unconnected with the influence of cold; such are fluctuating tumours, usually about the knees, which require stimulating embrocations and the occasional use of the *budding-iron*, followed by the application of a blister when the fluid has escaped. Other tumours, also in the neighbourhood of joints, are of a hard character. They will generally yield to frictions with an ointment of the hydriodate of potash, this drug being also administered internally in doses of 6 or 8 grains daily. The too frequent consequence of these affections is *palsy*, at first confined to certain limbs, but gradually spreading over the frame, being however most visible in the hind extremities. Here again the whole treatment may be included in the comprehensive word 'comfort.' Small doses of physic, the administration of the white antimonial powder, the use of stimulating embrocations, with warm lodging and good food, especially mashes, will be useful adjuvants.

As for that species of nervous affection, *rabies* or *madness*, it admits not of cure; and it has but one cause, namely, the bite of a rabid or mad dog. If a farmer knows that certain beasts have been bitten, or has strong reason to suspect it, he will act wisely in sending them to the butcher, for after the disease has once appeared, there is no cure, and the meat is spoiled.

It is time to revert to the diseases of other systems and parts. Too frequent and destructive is that inflammation of the tongue and mouth, recognised by the name of *blain*. It consists of vesicles and tumours occupying the side of the tongue and the membrane of the mouth, speedily ulcerating, becoming gangrenous, producing much swelling of the face and head, and rapidly destroying the animal. It often appears under the form of an epidemic, and it is frequently contagious. The mouth should be well cleansed with a solution of the chloride of lime. Blood should be abstracted at an early period of the disease, and mild purgatives administered; but if the complaint has attained its height before any treatment is adopted, the chloride of lime should still be used, and also the physic, but it should be accompanied by some stimulating ingredients, as gentian or ginger, or both.

All cattle are subject to *fever*. The dry muzzle and the heat at the root of the horn, and the heaving at the flanks, are sufficient proofs of it. If this is early observed, a dose of physic and one or two mashes will usually set all right. At times however the attack is sudden and more violent, and danger is evident from the very commencement. The farmer recognises this affection by the terms *black-quarter*, *quarter-ill*, *blood-striking*, &c. The beast is seen with his head protruded, his nostrils expanded, and his flank heaving, the breath and horn hot, and the eyes bloodshot. There is a peculiar crackling sound if the loins are pressed upon, and the slightest pressure gives extreme pain. Ulcers appear on various parts of the body, and every part seems tending to corruption. This disease is sometimes epidemic, but it is quite as often the consequence of the fattening process being hurried on too rapidly. In the early stage of such a complaint, the treatment will consist of copious bleeding and brisk purging. These should be continued until they produce their effect, and then some sedative medicine, as foxglove or emetic tartar, administered, and persisted in until the disease is evidently yielding. After this some mild stomachics, as gentian and ginger, should be administered.

Too frequently however the treatment has not been sufficiently severe or was not commenced early enough, and a peculiar low fever begins to be apparent. There is dysentery, which no astringent will arrest; ulcers, which defy the power of every disinfectant; and the animal dies one mass of putridity. In this stage of the disease, and also in many of the complaints that have been described, the assistance of an educated veterinary surgeon should be requested, for the treatment is complicated and difficult to a great degree.

The diseases of the respiratory system require particular notice: most frequent among them is *cough*. It is too little regarded by the owner, but it is often the unsuspected messenger of consumption and death. There is no rule of more universal application in cattle practice than that a chronic cough is the forerunner of everything that is bad. While the beast feeds well and the muzzle is cool and moist, and the flanks are quiet, the dairyman feels no alarm, although he hears the cough almost every time that he enters the cow-house. By-and-bye however he finds that the cow is losing condition, and her quantity of milk is evidently diminishing, and he begins to think that there is some necessity for attending to the case. It is then too late: the seeds of consumption are sown, and he must part with her immediately, or she will pine away and die. In every case of severe cough, moderate bleeding and purgation should be had recourse to, with warm mashes and a comfortable cow-house. The same treatment will apply to the *epidemic catarrh*, which is sometimes so prevalent. When this catarrh assumes a malignant form, as in *murrain*, the treatment will be little different from that of black-quarter. *Sore throat*, or inflammation of the upper part of the throat and the back of the mouth, should be treated as cough, except that a blister or some stimulating application should be had recourse to. The same may be said of *bronchitis*, but there is a peculiar form of it to which young cattle are subject, and which bids defiance to all medical treatment, namely, the choking of the windpipe and passages of the lungs by an innumerable host of minute worms. No medicine will be of avail here.

Cattle are comparatively seldom attacked by pure *inflammation of the lungs*. This disease principally occurs when the beasts have been compelled to travel too far or too fast, and when they are exposed to sudden variations of temperature. It may be known by the drooping head, the heaving flank, the frequent painful cough, the obstinate standing, the hot mouth, and the cold feet. The animal should immediately be bled until the pulse falters. In all cases of inflammation and danger, this is the guide. No specific quantity should be ordered or taken. The faltering of the pulse is the unerring indication of the abstraction of the proper quantity. If the pulse again throbs loudly, the bleeding should be repeated. The bowels should be opened by means of Epsom salts. Setons in the dewlap should not be forgotten, and blisters should be rubbed on the sides with right good earnest. The diet should consist of thin gruel and mashes. *Pleurisy* may often be distinguished by a peculiar symptom, twitchings and shiverings about the chest and shoulders, these being the parts external to the seat of pain. Little waves appear to be stealing over the skin, and the animal shrinks when the sides are pressed upon. The treatment is the same as in inflammation of the lungs. *Consumption* is the most frequent and fatal of all the diseases of the chest in cattle. It is the consequence or the winding up of every other pulmonary complaint. It is distinguished by a feeble and hoarse cough, evidently accompanied by pain, and interrupted before it is perfectly completed. For awhile the beast may continue to thrive; she, for it is oftenest a disease of the female, may increase in condition; but she will presently begin to waste rapidly away. Medicine is powerless in this disease. The animal must be disposed of or destroyed.

First among the diseases of the *digestive* system is *choking*, or the stopping of a piece of carrot or turnip, or other hard substance, in its passage down the gullet. The cart-rope or the cart-whip is resorted to, in order to force it along the canal, and much mischief has ensued from the violence that has been resorted to on these occasions. Probangs are now constructed at trifling expense, and may be had from most surgical-instrument makers in town and country, by means of which the purpose may be readily effected and without danger.

From the gullet the food passes into the stomachs of the animal, of which there are four. The first is the *rumen*, or paunch, into which the imperfectly masticated food, as it is hastily gathered, descends. It is there macerated and prepared to be returned for a second or more complete grinding. Sometimes this stomach becomes overloaded with food: this is the *grain-sick* of the dairy. The animal refuses to eat, he becomes uneasy, moans, swells at the flank, and a kind of unconsciousness gradually steals upon him. The symptoms are often treacherous, and would deceive him who was not thoroughly acquainted with the diseases of cattle; but the introduction of the probang, if necessary, will reveal the real state of the case. The stomach-pump will be of admirable use here. Any quantity of fluid can be injected into the stomach, and the hardened mass may be rendered more fluid, and removed by means of the pump; or, if the stomach is too full to admit the probang, and to be thus evacuated, an incision may be made in the flank, and the accumulated mass withdrawn by the hand.

At other times an unnatural fermentation commences, and the stomach is inflated with gas. One look at the sides will sufficiently indicate the inflation of the paunch. This is termed *hoove*. The first indication of cure is to get rid of the gas. This may be accomplished by the introduction of substances that will chemically combine with it. The chloride of lime will effect this. The principal gas in the inflated stomach is hydrogen. The chlorine leaves the lime and combines with the hydrogen, and the compound does not occupy a thousandth part of the space previously occupied by the hydrogen. Two drachms of the chloride of lime will form a cheap and a very efficient agent. But if this is not at hand, then a puncture may be made into the left flank with perfect safety. If this is done with a trocar, the canula may remain in the wound, and the gas will continue to be extricated while any considerable portion of it remains. In default of a trocar, a penknife may be used; but as the upper portion of the stomach sinks with the disengagement of the gas, the aperture through the skin and that into the rumen will cease to be accurately opposed to each other; and some of the gas and the contents of the stomach will enter the cavity of the abdomen, and will be the cause of future illness, or peritonitis, or death.

The gas having escaped, a purgative should be administered, with a double dose of the aromatic, in order to excite the stomach to resume its duty.

The *loss of cud*, or the cessation of rumination, is only the indication or the consequence of other disease, and will cease with it. If the nature of that disease is not clear, a dose of physic, with the usual or more than the usual quantity of the carminative, may be given.

The diseases of the second stomach, the *reticulum*, or *honey-comb*, are few, and not easily distinguished. The simple function of that stomach is to prepare the pellet of food for remastication.

The third stomach, the *manyplus*, has more to do. The food which has not undergone sufficient comminution in the second mastication is seized by the rough and powerful leaves of this stomach, and is ground down, as it were, in a living mill. Sometimes however there is a deficiency of moisture in this stomach, or the muscular apparatus of the leaves does not act with sufficient energy, and at length the manyplus becomes perfectly paralysed by the distention caused in consequence of the undue quantity of food which is accumulated in it. This is known by the name of *fardel-bound*. The symptoms are not always evident. Dullness, want of appetite, disinclination to move, and costiveness, are among the usual indications. The treatment is simple, but too often ineffectual. It consists in the frequent administration of small doses of purgative medicine, with more than the usual quantity of carminatives; at the same time, a small stream of warm water is, by means of a horn or the stomach-pump, made to flow down the gullet and pass through the canal at the base of this stomach, thus gradually dislodging and washing away a portion of the accumulated and hardened contents.

The principal disease of the *abomasum*, or fourth stomach, is inflammation, designated by evident uneasiness, the resting of the muzzle on the situation of this stomach, or a peculiar stretching out of the fore-legs. Venesection and purgatives should be used in this case. Of the indications of disease in the *spleen* little is known. Inflammation is often found in it, with enlargement, induration, or softening of its substance. These circumstances however are rarely suspected during life.

To *diseases of the liver* these animals appear to be peculiarly-prone. A yellowness of the skin betrays the existence of biliary affections in a great proportion of the inhabitants of every dairy. When acute inflammation of the liver exists to any considerable extent, not only this yellow tint of the integument will be found, but tenderness on the right side, fullness there, and the direction of the muzzle to it. The proper remedies are those used in inflammation of other viscera, with the addition of blisters over the diseased part. Chronic inflammation is far more prevalent than that which is acute. The indications are, want of condition, the same tint of the skin, and obstinate cough. The remedies are gentle purgatives and succulent food. When obstruction of the biliary ducts takes place, there is a still deeper yellow, invariably accompanied by loss of condition. The animal then has *jaundice*, or the *yellows*. If much fever accompanies it, recourse must be had to bleeding and to physic.

Among the various intestinal diseases of the ox stands *enteritis*, or inflammation involving all the coats of the intestines. Young and fattening cattle are most subject to it. It is not however of very frequent occurrence, except as an epidemic, and then it is very destructive. *Wood-evil* and *moor-ill* are varieties of the same disease. They must be treated by bleeding, purgatives, blisters on the belly, mashes, and gruel.

Diarrhœa, or purging without the discharge of mucus mingling with the fæces, is produced by various causes, and particularly by a change or excess of food. It is often epidemic in the autumn. A mild purgative should first be given, and then the mingled but very efficacious medicine already recommended for a similar disease in calves.

Dysentery in the adult, as well as in the young animal, is indeed a fearful disease. Its causes are often obscure, and the means of successfully arresting its progress are a desideratum. Its principal characteristic is the discharge of mucus with the fæces, recognised by the appearance of bubbles standing for awhile on the fæces. The length of time which they continue there unbroken may be considered as a kind of admeasurement of the quantity of mucus actually discharged, or, in other words, of the danger of the case. The progress of the disease is rapid or slow according to circumstances which it is difficult to appreciate; but, in the usual course of things, the animal wastes away almost to a skeleton, and then dies.

Notwithstanding the purging, the first indication of cure is to bleed. It is an inflammatory disease, and that inflammation must be subdued. To the abstraction of blood should succeed the administration of an aperient, and castor oil, as being the least irritative, will be the best. Injections of gruel should follow; and, when the dung has somewhat resumed its natural character, astringents may be administered, at the very head of which, in this case, stands opium: a little calomel should perhaps be mingled with it as an alterative, and, after that, the vegetable tonics must perfect the cure. Cattle are subject to *flatulent* and *spasmodic colic*, for both of which the vegetable tonics will be the best cure, with a little of the chloride of lime to absorb the gas, and the abstraction of blood if there is any inflammatory action. Walking exercise and friction of the belly should not be omitted. For *strangulation* of the intestines there is seldom any cure but by means of an operation which a skilful veterinary surgeon alone can perform. In cases of *constipation*, the aperients must sometimes be long administered before the bowels will be opened. There will be no danger in this, provided the Epsom salts, alone or with a small portion of aromatic powder, are administered. *Dropsy* in cattle seldom admits of cure. Although an operation may be resorted to, the belly fills again, nor will any physic or diuretic arrest the evil.

Among the supposed diseases of the urinary organs, but much oftener of the digestive ones, stands *red-water*, so called from the colour of the fluid which is evacuated. It is materially connected with the pasture, but sometimes it has an epidemic character. In the acute form of the disease the water is red. This must be combated by bleeding and purging, until the bowels respond. In chronic red-water the urine has a brown tinge at first, but a red hue gradually mingles with it. This is difficult to treat. The principal hope of cure consists in the exhibition of Epsom salts until thorough purging is produced. Some mild carminative may then be given. *Black-water* is only a variety, or the concluding stage of red-water.

Puerperal fever, or dropping after calving, is a disease that has been very much misunderstood. A few days after calving, the cow suddenly loses all power over her hind limbs. She falls, and continues down three, four, or more days, until the power of voluntary motion returns, or she dies. It is inflammation of the womb or of the spinal cord, which extends to the organs of motion in the hind extremities. She must generally be bled, and always purged. No half measures will do here; the bowels being once opened, the cow will frequently get up, and there will be an end of the matter. Injections will materially assist the action of the physic. Whatever apparent weakness there may be, no tonic must be given until the bowels have been well opened.

Garget is inflammation or ulceration of the udder. The milk coagulates in the bag, and produces inflammation there. In an early stage, the sucking of the calf will afford the greatest relief. If this does not succeed, fomentation must be had recourse to, and friction with an unguent composed of elder-ointment with an eighth part of camphor, and mercurial ointment. To this, if necessary, iodine may succeed, but it must be a last resource, on account of its absorbent power.

The treatment of *cow-pox* will consist in fomenting the teats, applying an emollient ointment, and giving a little physic.

The diseases of the feet must not be forgotten. *Foul in the foot* consists in ulceration about the coronet or between the claws, which produces great lameness, and, occasionally, loss of the hoof. It is very contagious. The treatment is simple. Every pustule or collection of purulent matter must be opened; the horn which is separated from the parts beneath must be carefully and wholly removed; a linseed-meal poultice applied for a day or two, and then the sores touched with the *butyr of antimony*.

Mange is a too frequent and very troublesome disease among cattle. An ointment however, the basis of which is sulphur, with a small portion of mercurial ointment, daily and well rubbed on every affected part, will usually remove the complaint. Sulphur given internally will be a useful adjunct.

ASIATIC OXEN.

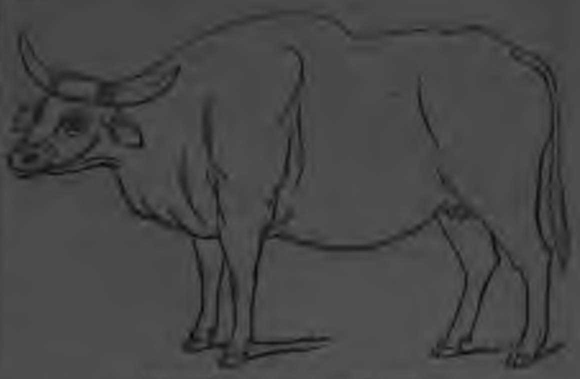
Mr. Bennett (*Gardens and Menagerie of the Zoological Society*), treating of the Indian Ox (*Bos Taurus*, var. *Indicus*), says,—'In addition to the domesticated species known by the names of Oxen, Buffaloes, and Yaks, the genus Bos comprehends several others equally distinct, which have rarely if ever been reclaimed from their native wildness. Two of these, the Bison and the Musk Ox, are peculiar to the northern regions of America; one, the Polish Aurochs, is now confined to a single European forest; a fourth, the *Arni*,* exists only in Central Asia; and a fifth, the Cape Buffalo, is, as its name imports, a native of the southern extremity of Africa. Thus it appears that in this wide dispersion of the several races, each region has preserved its own peculiar kind in its original independence; while, on the other hand, two at least of the remaining species, the Ox and Buffalo, which are no longer to be found in a state of nature, have been industriously propagated under the auspices of man, throughout almost every part of the globe. The Yak alone, of all the domestic species, remains confined within its primitive limits, in Thibet namely, and a part of Tartary, where it is said to be generally cultivated, almost to the exclusion of every other race.'

We proceed to notice first certain wild Asiatic oxen.

Bos Gavæus, *Gavaya*, Sansc.; *Gavai* or *Gayál*, Hind.; *Gobaygoya*, Beng.; *Gaujangali*, Pers.; *Mithun*, Mountaineers (Cúcis, &c.) east of Silhet; *Shiál*, Mountaineers (Cúcis) east of Chatgaon; *Tshongmoa*, Mugs; *Nówa*, Burmas; *Gauvera*, Ceylon.

Description.—Nearly of the size and shape of the English bull. It has short horns, which are distant at their bases, and rise in a gentle curve directly out and up: a transverse section near the base is ovate, the thick end of the section being on the inside. The front is broad, and crowned with a tuft of lighter coloured long curved hair. The dewlap is deep and pendant. It has no mane nor hump, but a considerable elevation over the withers. The tail is short, the body covered with a tolerable coat of straight dark brown hair; on the belly it is lighter coloured; and the legs and face are sometimes white. (Roxburgh.)

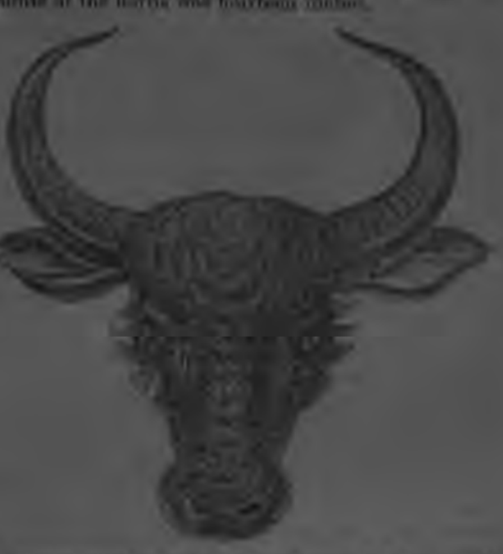
Habits, Locality, &c.—Dr. Buchanan states that the cry of the *Gayál* has no resemblance to the grunt of the Indian Ox; but a good deal resembles that of the buffalo. It is a kind of lowing, but shriller, and not near so loud as that of the European Ox. In this the *Gayál*, in Dr. Buchanan's opinion, approaches much nearer than it does to the buffalo. Mr. Macrae states that the *Gayál* is found wild in the range of mountains that form the eastern boundary of the provinces of Aracan, Chittagong (Chatgaon), Tipura, and Silhet. The Cúcis, or Lunctas, a race of people inhabiting the hills immediately to the eastward of Chatgaon, have herds of them in a domesticated state. The animal is called *Gobay* in the Hindu Sástra, but seems however to be little known beyond the limits of its native mountains, except to the inhabitants of the provinces above mentioned. The same author informs us that the *Gayál* is of a dull heavy appearance; but at the same time of a form that indicates much strength and activity, like that of the wild buffalo. Its disposition is gentle; even in the wild state on its native hills it is not considered dangerous, never standing the approach of man, much less sustaining his attack. The Cúcis hunt the wild ones for the sake of their flesh. The *Gayál* is a timid animal, and prefers the tender shoots and leaves of shrubs to grass; it never wallows in mud like the buffalo. It is domesticated by the Cúcis, but does not undergo any labour. The cow goes eleven (?) months with young, gives but little milk, and does not yield it long; but that little is remarkably rich, almost equalling cream, which it resembles in colour; the Cúcis however do not make any use of the milk, but rear the *Gayáls* entirely for their flesh and skins, of which last, or rather their hides, they form their shields. These domesticated herds roam at large in the forests near their villages during the day, but return of their own accord at evening, being early taught to do this by being fed when young every night with salt, of which these animals are very fond. The Hindus, in the province of Chatgaon, will not kill the *Gayál* (their *Gobay*), which they hold in equal veneration with the cow, but they hunt and will readily kill [illegible] (*[illegible] Gayál* or *[illegible]*) as they do the wild buffalo. The form of the animal, and the way in which it carries its head, will be understood from the following figure, which is reduced from that by a native artist, prefixed to Mr. Colebrooke's paper (*Asiatic Researches*, vol. viii.), to which we refer the reader for further interesting particulars.



The Gayál, Bos Gavæus. (Colebrooke.)

Mr. Bird proved that the Gayál will breed with the common Indian bull: he brought a domesticated female *Gayál* from Chittagong to Dacca, directed a common bull (of the breed *Gówalli*, a *Zebu* of the common kind found in the middle districts of Bengal), which the female received upon being blinded with a cloth thrown over her eyes. The offspring was a cow resembling mostly the *Gayál* mother; and from that cow, impregnated by a bull of the same common breed, another cow was produced, which also had grown up, and was in calf by a common bull when Mr. Bird wrote his account. (*Asiatic Researches*, vol. viii.)

General Hardwicke gives a figure of the head of the true wild, or as the natives term it, the *Asseel Gayál* (a female), from the south-east frontier of Bengal. The space between the points of the horns was fourteen inches.



Head of true or Asseel Gayál (female), Bos Gavæus? S. E. frontier of Bengal (from Hardwicke).

Bos Frontalis, Lambert, *The Gyall*.

Description.—Bluish-black, a grey frontal band; horns thick, remote, and short; tail rather naked, slender, and with a hairy extremity.

Mr. Lambert observes that the hair of the hide is soft; there is no crest; the lower lip is white at the apex, and bristled with hairs. The band of the *forehead*, including the bases of the horns, is lead-colour; the horns themselves are pale. Length from the tip of the nose to the end of the tail, nine feet two inches. From the tip of the hoof of the fore-foot to the top of the rising of the back, four feet one inch and a quarter. From the tip of the hoof of the hind leg to the highest part of the rump, four feet and a half.*

---

* [illegible]

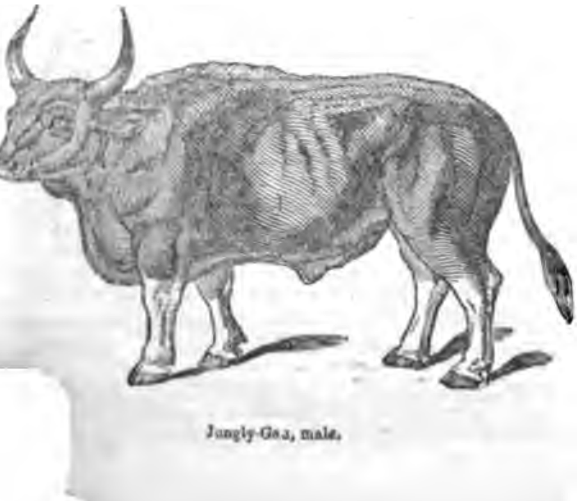
* If the figure given in 'Linn. Trans.' be correct, and great care is generally taken in this respect, there must be some error here. In the engraving the withers of the animal are considerably higher than the rump. 'Perhaps "four feet and half an inch" was meant.' Mr. Harris indeed, in his letter to Mr. Lambert, states that some parts of the drawing (which was taken in England, before the subject, which had been imported, died, and which appears to have been sent to Mr. Harris) seem to be rather too much enlarged, as for instance, the bases of the horns and the rising between the shoulders.

Mr. Harris, in his letter to Mr. Lambert, after identifying his animal with Mr. Lambert's drawing, writes thus:—'The animal * * which I have kept and reared these last seven years, and know by the name of the *Gyall*, is a native of the hills to the north-east and east of the Company's province of Chittagong, in Bengal, inhabiting that range of hills which separates it from the country of Aracan. The male Gyall is like our bull in shape and appearance, but, I conceive, not quite so tall; is of a blackish-brown colour; the horns short, but thick and strong towards the base, round which and across the frons the hair is bushy and of a dirty white colour; the chest and forehead are broad and thick. He is naturally very bold, and will defend himself against any of the beasts of prey. The female differs little in appearance; her horns are not quite so large, and her make is somewhat more slender; she is very quiet, is used for all the purposes of the dairy, as also (I have been informed by the natives) for tilling the ground, and is more tractable than the Buffalo. The milk which these cows give has a peculiar richness in it, arising, I should conceive, from their mode of feeding, which is always on the young shoots and branches of trees in preference to grass. I constantly made it a practice to allow them to range abroad amongst the hills and jungles at Chittagong during the day to browse, a keeper attending to prevent their straying so far as to endanger losing them. They do not thrive in any part of Bengal so well as in the aforementioned province and in the adjoining one, Tipperah, where I believe the animal is also to be found. I have heard of one instance of a female Gyall breeding with a common bull.'

Head of Gyall. ('Linn. Trans.')

The *Jungly-Gau, Bœuf des Jongles* of M. Duvaucel, *Bos Sylhetanus* of F. Cuvier, is considered to be identical with *Bos frontalis* of Lambert.

M. Duvaucel states that he believed for a long time that these oxen did not differ essentially from our domestic oxen, and that they were both varieties of the same species; but he had then only seen the specimens living in the menagerie at Barrackpore, whereas he had since hunted them at the foot of the Silhet mountains, and he found that they were as common and as much spread as the Buffaloes. But he adds that they seem more wild, though they are nevertheless easily domesticated, and yield abundance of the richest milk.



Jungly-Gau, male.

Bos Gour, Traill.

Dr. Traill remarks that the only animal which appears to have affinity with the *Gour* is the *Bos Gavæus* of Colebrooke, but the very different form of its head, the presence of a *distinct dewlap*, and the general habit of the *Gaijal* or *Gayâl*, distinguish it from the *Gour*. Captain Rogers assured Dr. Traill that neither the descriptions in Mr. Colebrooke's communication nor the figure of the Gayâl that accompanies them had any greater resemblance to the Gour than that general one which subsists between all the animals of this genus.

Description.—Form not so long as that of the *Urna* (*Arnee* or *Arni*). Back strongly arched, so as to form a nearly uniform curve from nose to base of tail when the animal stands still. This appearance is partly owing to the curved form of the nose and forehead, and still more to a remarkable ridge, of no great thickness, which rises six or seven inches above the general line of the back, from the last of the cervical to beyond the middle of the dorsal vertebræ,* from which it gradually is lost in the outline of the back. It was very conspicuous in the Gours of all ages, although they were loaded with fat; and has no resemblance to the bunch which is found on some of the domestic cattle of India. It bears some resemblance to the ridge described as existing in the Gayal, but the *Gour* is entirely without a dewlap, of which there is no trace in either sex at any age. End of the tail bushy.

Colour.—Very deep brownish-black, almost approaching to bluish-black, except a tuft of curling dirty white hair between the horns, and rings of the same colour just over the hoof. Hair of the skin short and sleek, having somewhat the oily appearance of a fresh seal-skin. (Traill.)

The shape of the horns will be best understood by reference to the cut; when polished, they are of a horn-grey colour with black solid tips. A pair in Dr. Traill's possession measured one foot eleven inches along their convex sides, and one foot in their widest circumference.

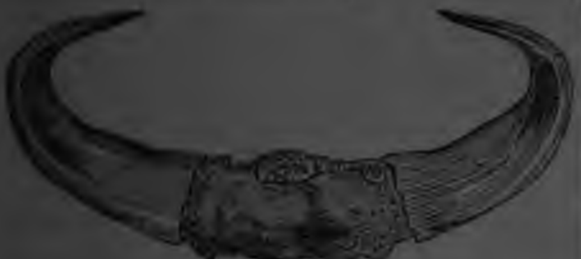
The size of the animal is considerable. Dr. Traill gives the dimensions of one *not fully grown*, which measured from tip of nose to end of tail 11 feet 11¾ inches; from the hoof to the withers 5 feet 11¾ inches; and from the withers to the sternum 3 feet 6 inches. 'The limbs have more of the form of the deer than any other of the bovine genus.'

Locality, Habits, Chace, Reproduction, &c.—The *Gour*, according to Captain Rogers, occurs in several mountainous parts of Central India, but is chiefly found in Myn Pât, or Mine Paut, a high insulated mountain with a tabular summit, in the province of Sergojah, in South Bahar. 'This table-land is about thirty-six miles in length by twenty-four or twenty-five miles in medial breadth, and rises above the neighbouring plains probably 2000 feet. The sides of the mountain slope with considerable steepness, and are furrowed by streams that water narrow valleys, the verdant banks of which are the favourite haunts of Gours. On being disturbed they retreat into the thick jungles of *Saul-trees* which cover the sides of the whole range. The south-east side of the mountain presents an extensive mural precipice from twenty to forty feet high. The rugged slopes at its foot are covered by impenetrable green jungle, and abound with dens formed of fallen blocks of rock, the suitable retreats of tigers, bears, and hyænas. The western slopes are less rugged, but the soil is parched, and the forests seem withered by excess of heat. The summit of the mountain presents a mixture of open lawns and woods. There were once twenty-five villages on Myn Pât, but these have been long deserted on account of the number and ferocity of the beasts of prey. On this mountain however the Gour maintains his seat. The Indians assert that even the tiger has no chance in combat with the full-grown Gour, though he may occasionally succeed in carrying off an unprotected calf. The wild Buffalo abounds in the plains below the mountains, but he so much dreads the Gour, according to the natives, that he rarely attempts to invade its haunts; and the hunting-party only met with three or four urnas on the mountain. The forests which shield the Gour abound however with Hog-deer, Saumurs (Sambur deer), and Porcupines.' Captain Rogers, who furnished the above account, hunted the Gour in these wild and romantic retreats, and the animal, it appears, when he faces his adversary ready to do battle. A short bellow, imitated best by the syllables *Ugh-ugh*, was the only cry heard from the Gour, and that not until after it had been wounded. August is the month in which the calf is generally dropped, and the period of gestation is twelve months. The large quantity of milk given by the cow is averred to be occasionally so rich as to cause the calf's death. The first year, the native name of the bull-calf is *Purorah*; the cow-calf is called *Pureeah*; and the full-grown cow *Gudrin*. The Gours herd together in parties varying from ten to twenty; they browse on the leaves and tender shoots of trees and shrubs, and also graze on the banks of the streams. In the cold weather the *saul* forests are their places of concealment, and the heats bring them out to feed in the green lawns and valleys. They do not, it seems, wallow in swamp and mire like the Buffalo. If the natives are to be credited, the Gour will not brook captivity; even if taken very young, the mountain-calf droops and dies. (*Edinburgh Philosophical Journal*, vol. xi.)'

---

* M. Lesson observes that M. Geoffroy found a row of accessory apophyses (*apophyses montantes suradnesées*), which are the cause of the vaulted back, and called by M. Geoffroy *pro-épial* and *ex-épial*.

General Hardwicke (*Zoological Journal*, vol. iii.) gives a figure of a pair of horns of the '*Bos Gour* or wild bull of the mountainous district of Ramgurh, and table-land of Sirgoojah,' from which our cut is taken. The gour to which they belonged was killed, as General Hardwicke believed, by the same hunting-party described by Captain Rogers, and they were presented to the General by the principal member of that party, the late Major Roughsedge. These horns were 15 inches between the tips.

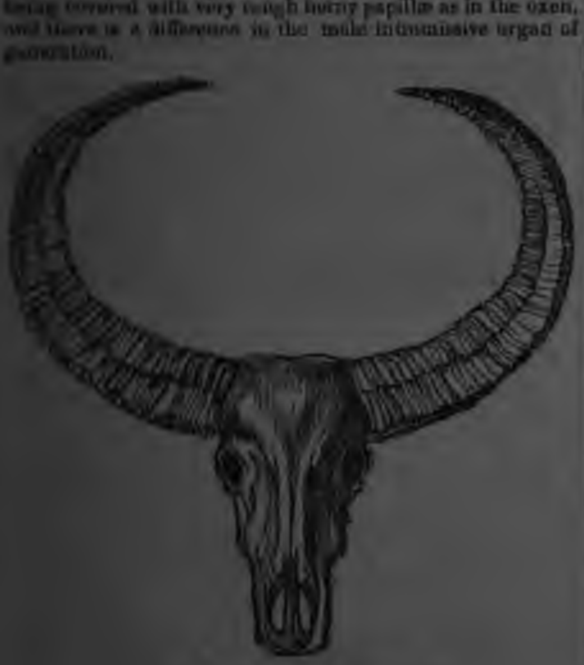


Horns of Gour. (Hardwicke.)

Bos Bubalus; *Le Buffle* of Buffon; *Le Buffle d'Italie* of F. Cuvier.

Description.—Front elevated, and rounded, so that the chanfrein has a concave appearance; horns black, separated widely from each other, with a projecting ridge anteriorly; dewlap but little developed; tail long and pendant; hide black, the hairs stiff and not numerous.

The tongue is very smooth in the buffaloes, instead of being covered with very rough horny papillæ as in the oxen, and there is a difference in the male intromissive organ of generation.



Skull and Horns of the Arnee.

The female buffalo goes longer with young than the cow; their milk is excellent, and they may be milked in the same way as a cow, notwithstanding some tales to the contrary.

Habits.—The buffalo is wild and fierce, lives in large herds in moist and marshy places, and delights to roll in the mire.

Geographical Distribution.—Asia generally, Africa, and southern Europe. In Italy, where it was introduced, it exists in the Pontine marshes.

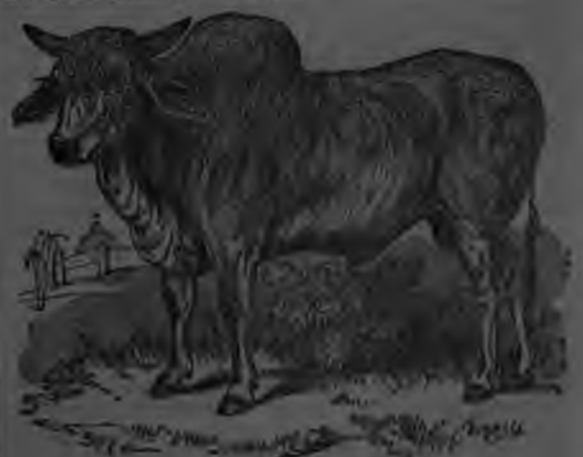
The *Bos Arni* of Shaw and others, the *Arnee* or *Urna*, no longer holds a place as a species, being considered, on good evidence, a variety of *Bos Bubalus*. Mr. Colebrooke, in his interesting paper on the Gayal (*Bos Gavæus*) above noticed, says, 'The Bos Arnee of Kerr and Turton, notwithstanding the exaggerated description given on the authority of "a British officer who met with one in the woods in the country above Bengal," is evidently nothing else but the wild buffalo, an animal very common throughout Bengal, and known there and in the neighbouring provinces of Hindustan by the name of *Arna*.' 'Though neither fourteen feet high, as Mr. Kerr has stated, or rather as the officer on whose information he relied, had affirmed; nor even eight feet, as Dr. Turton, following Kerr's inference from a drawing, asserts; yet it is,' says Mr. Colebrooke, 'a large and very formidable animal, conspicuous for its strength, courage, and ferocity.' (*As. Res.*, vol. viii.)

The domesticated Asiatic oxen, or zebus, vary much in their size and the direction of their horns, but are generally distinguished by a fatty elevated hump below the neck and over the withers. They are to be found in the catalogues under the names of *Bos Indicus*, Erxl., and (more correctly) *Bos Taurus*, var. *Indicus*, Desm. and others.

The horns of some are short and suberect (Indian ox), in others comparatively long and pointed backwards, with an inclination to curve inwards, as in the more common breeds (Zebu). The ears of some are of ordinary size and position (Zebu); in others pendulous (Indian ox). The dewlap is more or less developed, in some very largely. Their colour varies from a light ashy grey to a milk white, and their size from the stature of an ordinary bull to that of a large mastiff. Many of these varieties may be seen in the gardens of the Zoological Society in the Regent's Park. The limbs of all are deer-like and elegant. They 'are spread,' says Mr. Bennett, 'over the whole of Southern Asia, the islands of the Indian Archipelago, and the eastern coast of Africa, from Abyssinia to the Cape of Good Hope.'

In many parts of India the Zebu is placed under the saddle or harnessed to a carriage, and travels at an easy rate. It must have lost much of its fleetness, if the more antient writers are to be credited; for they speak of fifty or sixty miles a day as its usual pace, whilst the moderns only allow it twenty or thirty. The beef is not bad, but is neither so sweet nor so good as that of the common ox, the hump always excepted, which when well cooked is very delicate.

The Zebus bear a charmed life among the Hindus, who venerate them and hold their slaughter to be a sin; though they do not object to work them. There are however some particularly sanctified zebus who lead an easy life, wandering about the villages at their ease, and taking their pleasure and their food where they list, if not prevented by the contributions of the devout.

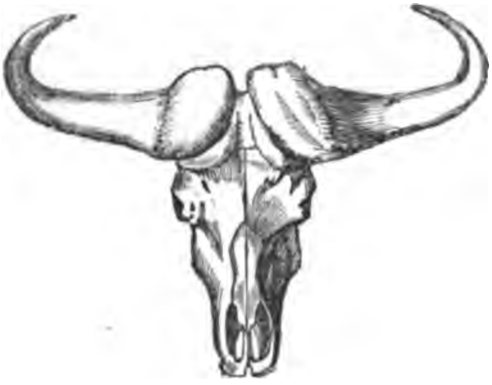


Indian Ox (large variety).

AFRICAN OXEN.

Bos Caffer. The Cape Buffalo.

Description.—Horns black, extremely large and flattened at their base, where they cover the front, having a direction from within outwards and downwards, and then again elevated at their point; ears rather pendant and covered by the horns; dewlap large and pendant; skin with harsh hairs an inch long of a deep brown or black colour. Size great, and proportions massive.



Skull of Bos Caffer.

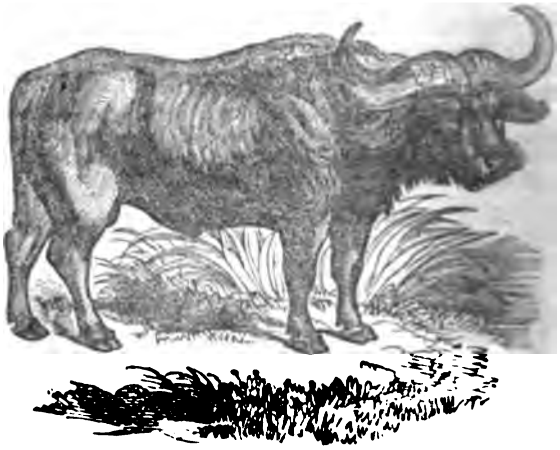
Locality.—South Africa.

Habits, &c.—The Cape buffalo congregates in large herds. Thunberg and his companions came suddenly upon a mass of five or six hundred, which were grazing in a plain skirted by a wood. The beasts did not see the intruders till they came within three hundred paces, when the whole herd lifted their heads and stood at a gaze. After a while the buffaloes stooped their heads again to feed, and six of the party (three Europeans and three Hottentots), who carried muskets and were accompanied by others armed with javelins, marched up to them within forty paces, when the herd again lifted their heads and were saluted with a volley, which instantaneously dispersed them, leaving their wounded to follow as they could. One of these, an old bull, made the travellers fly, but fell before he reached the wood. This beast was very thick in the body, with short legs, of a dark grey colour, and almost destitute of hairs. But if a herd may be approached thus safely, a single outlying bull or a wounded one appears to be a most formidable antagonist. The author last quoted was botanising in a wood rather behind his companions, when Auge, the gardener of the expedition, who went first, suddenly encountered a large old male buffalo, which was lying down quite alone in a spot of a few square yards free from bushes. No sooner did the beast discover the poor gardener, than he rushed upon him with a terrible roar. Auge turned his horse short round behind a great tree, so as in some measure to get out of the sight of the buffalo, which now charged straight towards the serjeant who followed, and gored his horse in the belly so terribly that it instantly fell on its back, with its feet turned up in air and its entrails hanging out, in which state it lived almost half an hour. In the mean time the gardener and serjeant had climbed up into trees for safety. Thunberg, intent upon his botanising, and with his ears filled with the rustling of the branches, in the narrow pass where he was, against his saddle and baggage, heard nothing of all this, though so near. But the buffalo had not done yet. The serjeant had brought two horses with him for his journey. One of them, as we have seen, had been already despatched; the other now stood just in the way of the buffalo as he was going out of the wood. As soon as the infuriated beast saw this second horse, he attacked it so furiously, that he not only drove his horns into the horse's breast and out again through the very saddle, but threw it to the ground with such violence that it instantly expired, and all the bones of its body were broken. Just as the buffalo was thus engaged with this last horse, Thunberg came up to the opening and beheld the frightful scene. The wood was so thick that he had neither room to turn his horse round, nor to get on one side; he therefore was obliged to take refuge upon a tree into which he climbed, leaving his horse to its fate. But the buffalo had satiated his rage or did not distinctly see the new object, for after his second exploit, he turned suddenly round and went off. Thunberg found his companions half dead with fear, indeed the gardener was so affected that he could scarcely speak for some days after, and the two surviving horses were discovered shivering with fear, and unable to make their escape. (*Travels.*)

Sparrman (*Voyage to the Cape*, vol. ii.) gives a graphic description of the shooting of one, and of the unconquerable spirit of the animal even in death. We can only find room for the final act of the tragedy. 'During his fall, and before he died,' writes Sparrman, 'he bellowed in a most stupendous manner; and this death-song of his inspired every one of us with no small degree of joy, on account of the victory we had gained: and so thoroughly steeled frequently is the human heart against the sufferings of the brute creation, that we hastened forwards, in order to enjoy the pleasure of seeing the buffalo struggle with the pangs of death. I happened to be the foremost amongst them; but think it impossible ever to behold anguish, accompanied by a savage fierceness, painted in stronger colours than they were in the countenance of this buffalo. I was within ten steps of him, when he perceived me, and, bellowing, raised himself suddenly again on his legs. I had reason to believe since, that I was at the time very much frightened; for before I could well take my aim, I fired off my gun, and the shot missed the whole of his huge body, and only hit him in the hind-legs, as we afterwards discovered by the size of the ball. Immediately upon this I fled away like lightning, in order to look out for some tree to climb up into.' The same author gives the following as the measurement of a buffalo. Length 8 feet, height 5½ feet, and the forelegs 2½ feet long: the larger hoofs 5 inches over. The distance between the points of the horns he states to be frequently 5 feet. They are black, and the surface, to within about a third part of them, measured from the base, is very rough and craggy. A very lively account of a buffalo-hunt is also given by Bruce. He guesses the weight of a bull that he assisted in killing at nearer fifty than forty stone. The horns from the root, following the line of their curve, were about 52 inches, and nearly nine where thickest in circumference.

The Cape buffalo delights in wallowing in the mire, and when heated by hunting throws himself into the first water he reaches.

The flesh is described by some as good and high flavoured, by others as ill-grained and coarse: the difference in these accounts is probably to be traced to the sex, age, and condition of the animals eaten. The rhinoceros-like hide is much sought after for harness, &c.



Bos Caffer.

The horns of the domesticated oxen of the Cape grow to an enormous size.

AMERICAN OXEN

Bison.

Bison Americanus. (See the article BISON.)

Our readers have only to open almost any one of the numerous books of South American Travels for an account of the wild or half-wild cattle, and the mode of capturing and slaughtering them. Mr. Darwin (*Journal of Researches in Geology and Natural History*, 8vo. London, 1839) informs us that the great *corral* at Buenos Ayres, 'where the animals are kept for slaughter to supply food to this beef-eating population, is one of the spectacles best worth seeing. The strength of the horse, as compared to that of the bullock, is quite astonishing: a man on horseback having thrown his lazo round the horns of a beast, can drag it anywhere he chooses. The animal having ploughed up the ground with outstretched legs in vain efforts to resist the force, generally dashes at full speed to one side; but the horse immediately turning to receive the shock, stands so firmly, that the bullock is almost thrown down, and one would think, would certainly have its neck dislocated. The struggle is not however one of fair strength, the horse's girth being matched against the bullock's extended neck. In a similar manner a man can hold the wildest horse, if caught with the lazo just behind the ears. When the bullock has been dragged to the spot where it is to be slaughtered, the *matador* with great caution cuts the hamstrings. Then is given the death-bellow; a noise more expressive of fierce agony than any I know: I have often distinguished it from a long distance, and have always known that the struggle was then drawing to a close. The whole sight is horrible and revolting: the ground is almost made of bones; and the horses and riders are drenched with gore.' The same interesting writer gives an account of the chase of a wild fat cow in the Falkland Islands with the *bolas* and *lazo*, nor does he forget to celebrate the delicious supper of 'carne con cuero' which it afforded him. A large circular piece was taken from the back, roasted on the embers with the hide downwards, and in the form of a saucer, so that none of the gravy was lost. The flesh thus treated was as superior to common beef as venison is to mutton.

Ovibos.

Generic Character.—Horns very wide, and touching each other at their base, then applied to the sides of the head, and having the points suddenly turned up. No naked muzzle; but no furrow on the upper lip. Chaffron narrow at the end, very square, resembling that of the sheep. Ears short. Limbs robust. Tail very short.

Musk Ox (*Ovibos moschatus*).

Ovibos moschatus.

Description.—Size of Highland cattle. Horns broad at origin, covering the brow and whole crown of the head, and touching each other throughout from before backwards. As each horn rises from its fairly convex base, it becomes round and tapering, curving directly downwards between the eye and the ear, until it reaches the angle of the mouth, when it turns upwards in the segment of a circle to above the level of the eye; for half its length it is dull, white, and rough, and beyond smooth and shining; near the point it becomes black.

General colour of the hair brown, long, matted, and rather curled on the neck and between the shoulders, where it is rather crested; on the back and hips long but lying smoothly. On the shoulders, sides, and thighs it is so long as to hang down below the middle of the leg. There is on the centre of the back a mark of a soiled brownish white, called by Captain Parry the saddle. On the throat and chest the hair is very straight and long, and, together with the long hair on the lower jaw, hangs down like a beard and dewlap. The short tail is concealed by the fur of the hips. There is a large quantity of fine brownish ash-coloured wool or down among the hair covering the body. The hair on the legs is short, dull brownish-white, unmixed with wool. The hoofs are longer than those of the *Caribou*, but so similar in form that it requires the eye of a practised hunter to distinguish the impressions. In the cow, which is smaller than the bull, the horns are smaller, and their bases, instead of touching, are separated by a hairy space. The hair on the throat and chest is also shorter. (Richardson.)

This is the *Bœuf musqué* of Jérémie; *Musk Ox* of Drage, Dobbs, Ellis, Pennant, Hearne, and Parry; *Bos moschatus* of Gmelin, Sabine, and Richardson (Parry's 'Second Voyage'); *Matèeh-moostoos* (ugly bison) of the Cree Indians; *Adgiddah-yawseh* (little bison) of the Chepewyans and Copper Indians; and *Oomingmak* of the Esquimaux. (Richardson.)

Geographical Distribution.—The barren lands of America lying to the northward of the 60th parallel. Tracks were once seen by Hearne within a few miles of Fort Churchill, in lat. 59°; and he saw many in his first northern journey, in about lat. 61°. Dr. Richardson was informed that they do not now come so far to the southward even on the Hudson's Bay shore; and he adds that farther to the westward they are rarely seen in any numbers lower than lat. 67°, although from portions of their skulls and horns, which are occasionally found near the northern borders of the Great Slave Lake, he thinks it probable that they ranged at no very distant period over the whole country lying between that great sheet of water and the Polar Sea. He had not heard of their having been seen on the banks of Mackenzie's River to the southward of Great Bear Lake, and he states that they do not come to the south-western end of that lake, although they existed in numbers on its north-eastern arm. 'They range,' continues the Doctor, 'over the islands which lie to the north of the American continent, as far as Melville Island, in lat. 75°, but they do not, like the rein-deer, extend to Greenland, Spitzbergen, or Lapland. From Indian information we learn that to the westward of the Rocky Mountains, which skirt the Mackenzie, there is an extensive tract of barren country, which is also inhabited by the musk-ox and rein-deer. It is to the Russian traders that we must look for information on this head; but it is probable that, owing to the greater mildness of the climate to the westward of the Rocky Mountains, the musk-ox, which affects a cold barren district, where grass is replaced by lichens, does not range so far to the southward on the Pacific coast as it does on the shores of Hudson's Bay. It is not known in New Caledonia nor on the banks of the Columbia, nor is it found on the Rocky Mountain ridge at the usual crossing places near the sources of the Peace, Elk, and Saskatchewan rivers. It is therefore fair to conclude that the animal described by Fathers Marco de Niza and Gomara as an inhabitant of New Mexico, and which Pennant refers to the musk-ox, is of a different species. The musk-ox has not crossed over to the Asiatic shore, and does not exist in Siberia, although fossil skulls have been found there of a species nearly allied, which has been enumerated in systematic works under the name of *Ovibos Pallantis*. The appearance of musk-oxen on Melville Island in the month of May, as ascertained on Captain Parry's first voyage, is interesting, not merely as a part of their natural history, but as giving us reason to infer that a chain of islands lies between Melville Island and Cape Lyon, or that Wollaston and Banks' Lands form one great island, over which the migrations of the animals must have been performed. The districts inhabited by the musk-ox are the proper lands of the Esquimaux; and neither the northern Indians nor the Crees have an original name for it, both terming it Bison with an additional epithet.'

Habits, Chase, Utility, &c.—Dr. Richardson, who had the best opportunities of coming at the truth, informs us that the country frequented by the musk-ox is mostly rocky and destitute of wood, except on the banks of the larger rivers, which are more or less thickly clothed with spruce trees. Their food, he tells us, is similar to that of the *Caribou* [DEER, vol. viii., p. 355], grass at one season and lichens at another; and the contents of its paunch are eaten by the natives with the same relish as that with which they devour the 'nerrooks' of the Caribou. The dung is voided in round pellets, which are larger than those which come from the Caribou. The animal runs fast, short as are its legs, and hills and rocks are easily climbed by this ox of the northern deserts. One pursued by Dr. Richardson's party on the banks of the Copper-mine River scaled a lofty sand-cliff with so great a declivity, that they were obliged to crawl on hands and knees to follow the chase. The musk-oxen assemble in herds of from twenty to thirty, are in their rut about the end of August and beginning of September, and bring forth one calf about the latter end of May or beginning of June. Hearne accounts for the few bulls which are seen by supposing that they kill each other in their contests for the cows.

Dr. Richardson thus graphically describes the terror of a huddled herd. 'If the hunters keep themselves concealed when they fire upon a herd of musk-oxen, the poor animals mistake the noise for thunder, and, forming themselves into a group, crowd nearer and nearer together as their companions fall around them; but should they discover their enemies by sight, or by their sense of smell, which is very acute, the whole herd seek for safety by instant flight. The bulls however are very irascible, and, particularly when wounded, will often attack the hunter, and endanger his life unless he possesses both activity and presence of mind. The Esquimaux, who are well accustomed to the pursuit of this animal, sometimes turn its irritable disposition to good account; for an expert hunter having provoked a bull to attack him, wheels round it more quickly than it can turn, and by repeated stabs in the belly puts an end to its life.'

Mr. Jeremie, who first brought the animal into notice, carried some of its wool to France, where some stockings were made of it, said to have been equal to the finest silk. Dr. Richardson says that this wool resembles that of the Bison, but is perhaps finer, and would, in his opinion, be highly useful in the arts, if it could be procured in sufficient quantity. The same author informs us that when the animal is fat, its flesh is well tasted, and resembles that of the Caribou, but has a coarser grain. The flesh of the bulls is high flavoured, and both bulls and cows, when lean, smell strongly of musk, their flesh at the same time being very dark and tough, and certainly far inferior to that of any other ruminating animal in North America. The carcass of a musk-ox weighs, exclusive of the offal, about three hundredweight, or nearly three times as much as a Barren-ground caribou, and twice as much as one of the woodland caribou. (*Fauna Borealis-Americana.*)

Utility to Man.—The true oxen hold the first rank among the animals which are useful to man. The domesticated varieties, in their life and in their death, minister largely to his wants. From the earliest times we find it in the homestall; and there is scarcely a part of the animal, from horn to hoof, when dead, that is not available for his use. It is not then a subject of wonder that in the dark ages the ox should have been considered as the representative of the Deity, and that India and Egypt should have venerated the form as that of a god.

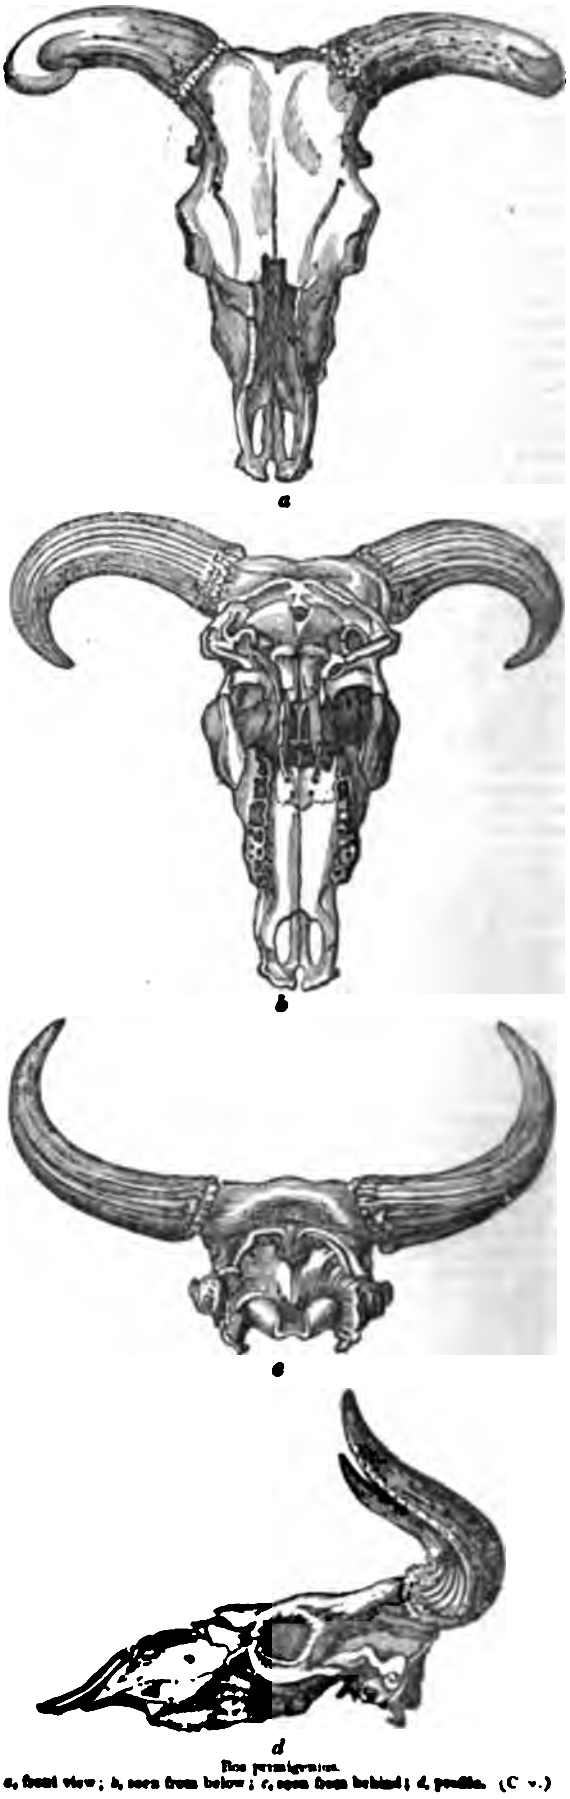
FOSSIL OXEN.

Remains of oxen and deer occur abundantly in the third and fourth periods of the tertiary series (Pliocene of Lyell), with extinct species of existing genera of Pachydermata, such as elephant, rhinoceros, hippopotamus, and horse, and the extinct genus Mastodon; and large *Carnivora*, *e.g.* tiger, hyæna, and bear.

At the head of these we must place *Bos primigenius*.

Mr. Woods, in the paper which we have above alluded to, remarks that 'it has occasioned some speculation among zoologists to appropriate to the large herbivorous animals, of which these skulls and scattered bones are now the only vestiges, their proper place in the system of nature. Cuvier however has fixed their characters, and has declared them to resemble the skulls of the present oxen so closely, that there can be little doubt of their having belonged to the stock from which the latter have all proceeded; these having however degenerated in size, and varied from them and from each other in minor points, owing to differences in climate, food, and other causes depending upon domestication, their magnitude is at least one-third greater than that of the largest breed of modern oxen, and their horns are much more massive.'

'The species with which they have been usually confounded is the Aurochs of Germany (Urus of the antients).



Bos primigenius.
a, front view; *b*, seen from below; *c*, seen from behind; *d*, profile. (C v.)

still found wild in some parts of north-western Europe, particularly the forests of Lithuania, &c.; but our admirable author has so clearly demonstrated the difference between the two, that the question, one would imagine, had long since been set at rest; yet in a comparatively recent work—a translation of the Baron's *Règne Animal*, with additions—the writer on the genus Bos has in a great measure again confounded these species, by applying to one, all that is supposed to have been related of the other; and to confirm the error, in the synopsis appended to the work, the domestic ox is actually made a mere variety of the *bos urus*—the aurochs, or bison.

'Cuvier thus carefully marks the distinction between the species: "The forehead of the ox is flat and a little concave; that of the aurochs protuberant, although less so than the buffalo's; the forehead is square in the ox, its height, taking its base between the orbits, being very nearly equal to its breadth; in the aurochs it is much wider than high, in the proportion of 3 to 2. The horns are attached in the ox to the extremities of a salient line, the most elevated of the head, that which separates the occiput from the forehead; in the aurochs this line is placed two inches farther backward than the roots of the horns: in the ox the plane of the occiput makes an acute angle with that of the forehead; in the aurochs this angle is obtuse: finally, the plane of the occiput is square in the ox, but represents a half circle in the aurochs." These characters,' continues our author, 'are constant in all the domestic races of every country.' And Mr. Woods further quotes from the 'Ossemens Fossiles' of Cuvier, who says, 'All the characters which I have assigned to the living oxen are united in the skulls of the fossil species, and I have no doubt but that they appertain to a wild race, very different from the aurochs, and which has been the true stock of our domestic oxen, a race which has been annihilated by civilization, as are those of the camel and dromedary.' The cores of the horns of the fine specimen found at Melksham and described by Mr. Woods measured, in their widest expansion, four feet within half an inch. The cranium, which consisted of the frontal bone, with the cores of the horns attached, perfect from their base to their extremities, the temporal, molar, ethmoid, sphenoid, upper maxillary, and occipital bones, with nearly all their various processes and condyles, weighed 63 lbs. Large as these dimensions are, specimens have been found exceeding this cranium in size.

Widely spread in Europe in the 'diluvium' bone-caves and bone breccias.

The following fossil species have been also named:—*Bos Trochoceros* (Hermann von Meyer), subapennine beds; *Bos (Bison) priscus* (Bojanus), *Buffle fossile de Siberie* (Cuv.), *Bos latifrons* (Harlan), *Broad-headed fossil Bison* and *Bison fossilis*, 'diluvium' of Europe and North America, bone caves and bone breccias; *Bos (Bison?) bombifrons* (Harlan), Big bone-lick, North America; *Bos Pallasii* (Dekay), *Bos moschatus fossilis? Bos canaliculatus* (Fischer)? Siberia and North America; *Bos velaunus* (Robert), Cussac, Haute Loire.

Abundant remains of ox were found by Capt. Cautley in the Sewalik Mountains, at the southern foot of the Himalaya, between the Sutlej and the Ganges, partly lying on the slope among the ruins of fallen cliffs, and partly in situ in the sandstone, in company with the bones of mastodon, elephant, rhinoceros, hippopotamus, hog, horse (comparatively scarce), elk, deer, several varieties; carnivora, ursus and felinæ (comparatively scarce); crocodile, gavial, emys, trionyx, and fishes. There were also portions of undescribed mammalia.

⁂ We now proceed to give a sketch of the views of zoologists with regard to the animals which belong to the *Bovidæ*.

The Linnæan genus *Bos*, in the last edition of the 'Systema Naturæ,' as it was left by its great author, comes next to *Ovis*, and is the last of the *Pecora*. It consists of the following species:—*Taurus*, with its varieties, including *Cæsar's Urus*; *Bonasus*; Bison and its variety, *Bison Americanus*; *Grunniens* (Yak); *Bubalis* (Bubalus of Ray, Buffalo of Asia and Italy); and *Indicus* (Zebu), with *Bubalus Africanus* as a variety.

In Illiger's system, the order *Bisulca*, consisting of the families *Tylopoda* (Camels), *Devexa* (Camelopard), *Capreoli* (Cervus and Moschus), and *Cavicornia* (Antilope, Capra, and Bos), stands between the *Solidungula* (Horse) and the *Tardigrada* (Sloths).

Cuvier, like Linnæus, places *Bos*, consisting of the *True Oxen* and the *Musk-Ox* (Ovibos), next to *Ovis*, and at the end of the Ruminants.

Mr. Gray makes the *Bovidæ* the first family of his fifth order, *Ungulata* of Ray, and divides that family as follows:—

† Horns persistent.

1. Bovina. Bos, Linn.; *Ovis*, Linn.; *Capra*, Linn.; *Antilocapra*, Ord.; *Antilope*, Brisson; *Catoblepas*, Gray.
2. Camelopardina. *Camelopardalis*, Linn.

†† Horns none or deciduous.

3. Camelina. *Camelus*, Linn.; *Auchenia*, Illiger.
4. Moschina. *Moschus*, Linn.; *Memina*, Gray.
5. Cervina. *Muntjacus*, Gray; *Cervus* and *Capreolus*, Gesner; *Axis*, Blainv.; *Cervus*, Linn.; *Dama*, Gesner; *Tarandus*, Pliny; *Alce*, Pliny.

Fischer (J. B.) arranges *Bos* at the end of the Ruminants, placing it next to *Capra*.

Col. Hamilton Smith, who has paid great attention to the family, has published his views, which are well worthy of the attention of zoologists, in Griffith's 'Cuvier,' to which we refer the reader. Mr. Swainson has adopted them in great measure.

The latter zoologist (1836) makes the *Bovidæ*, his first family of the *Ruminantes*, or ruminating quadrupeds, consist of the following genera:—*Catoblepas, Ovibos, Bos, Bubalus, Bison, Taurus*, Sm.; *Anoa*, Sm.; indeed the initial letters of Col. Smith's name stand at the end of each of the genera. The genus *Anoa* is placed by Col. Smith under his family *Capridæ*, a situation which Mr. Gray also assigns to it.

Mr. Ogilby's *Bovidæ* form the fifth and last family of the Ruminants, and include the following genera:—*Tragulus, Sylvicapra, Tragelaphus, Calliope, Kemas, Capricornis, Bubalus, Oryx, Bos* (type *Bos Taurus*). The genus *Ovibos* is arranged by him under the preceding family, *Capridæ* (*Zool. Proc.*, 1836.)

OX-EYE. [Titmice.]

OXALIC ACID. This acid was discovered by Scheele, in 1776. It occurs in several plants, as in the wood sorrel (*Oxalis acetosella*), and in common sorrel (*Rumex acetosa*). In the juice of these plants, and in the roots of rhubarb, bistort, gentian, &c., it is combined with potash; in several kinds of lichens, it is found in union with lime. It occurs as a mineral compound also, in combination with oxide of iron, and is called *Humboldtite*. It is an ingredient also of several urinary calculi.

Oxalic acid may be obtained by several processes: first, by decomposing the natural superoxalate of potash, or salt of sorrel, by means of acetate of lead, sulphuric acid, &c.; but it is best obtained by heating organic matter, such as sugar or potato starch, with nitric acid in a retort. Having been first obtained from sugar, it received the name of *saccharine acid*. Indeed most organic compounds which contain much carbon and no azote, may be converted into oxalic acid by the action and decomposition of the nitric acid; and hydrate of potash, in some cases, produces similar results. When nitric acid acts upon sugar or starch, it is decomposed, and yields nitric oxide gas in great quantity; the oxygen of the decomposed acid uniting with the carbon of the vegetable matter, converts it into oxalic acid: the crystals first obtained are to be dissolved in water and re-crystallized to render them perfectly pure.

The properties of oxalic acid are, that its crystals are prismatic, colourless, and transparent; the primary form is a right rhombic prism. Their taste is extremely sour, and they are very poisonous; when dissolved in 200,000 times their weight of water, the solution reddens litmus paper. When this acid is exposed to a dry air, it effloresces, losing water of crystallization; it dissolves in 15 parts of water at 50°, and in 9 parts at 60°; at 212° it melts in its water of crystallization; it is soluble also in alcohol, but less so than in water.

Oxalic acid consists of, in its anhydrous state,—

Three equivalents of oxygen .	24
Two equivalents of carbon .	12
	—
Equivalent . .	36

So that it is equal to

1 equiv. of carbonic oxide .	14 =	8 oxygen	+ 6	carbon.
1 ditto of carbonic acid .	22 =	16 ,,	+ 6	,,
	—			
	36			

No means have yet been discovered of forming oxalic acid by combining carbonic oxide and carbonic acid; but when oxalic acid is heated with sulphuric acid, it resolves into these substances entirely and in the proportions stated, the water of crystals combining with the sulphuric acid.

Oxalic acid, in the state of crystals, consists of one equivalent of acid 36 + three equivalents of water 27=63: this water cannot be totally expelled by heat; the acid, unless combined with a base, always retains one equivalent of water.

Oxalic acid is to a certain extent volatile, and Mr. Faraday has shown that sublimation takes place even at common temperatures; at 212° the volatilization is much more considerable; and when deprived of two-thirds of its water of crystallization, it sublimes rapidly and without decomposing; the sublimed acid is crystalline, and contains one equivalent of water.

When oxalic acid retaining the whole of its water of crystallization is suddenly heated up to about 300°, it yields carbonic acid, carbonic oxide, formic acid, and water.

Oxalic acid forms compounds with bases, which are termed oxalates, and of these we shall describe some of the more important.

Oxalate of Ammonia.—This salt is prepared by adding the sesquicarbonate of ammonia to a solution of the acid, to saturation. The solution by evaporation readily yields slender colourless prismatic crystals, the primary form of which appears to be a right rhombic prism. They are inodorous, but have a sharp saline taste. One hundred parts of cold water dissolve 4·5 parts of this salt; in hot water it is much more soluble. Alcohol does not take it up. When decomposed by heat, it yields a peculiar compound. [OXAMIDE.] This salt is composed of

One equivalent of oxalic acid	.	36
One equivalent of ammonia	.	17
One equivalent of water .	.	9
		—
Equivalent .	.	62

It is employed in solution as a test of the presence of lime.

Binoxalate of Ammonia may also be formed, but it is not of importance.

Oxalate of Potash.—Oxalic acid forms three salts with potash: the *neutral oxalate* is obtained by saturating the acid with the alcali. It crystallizes in flat rhombic crystals, which are so very soluble in water, that even when cold it takes up half its weight. When a solution of oxalic acid is added to this, precipitation of a less soluble supersalt occurs. It is composed of

One equivalent of oxalic acid	.	36
One equivalent of potash	.	48
One equivalent of water	.	9
		—
Equivalent	.	93

Binoxalate of Potash may be prepared either by dissolving the requisite quantities of acid and alkali in water, or, as above mentioned, by adding oxalic acid to the neutral salt. It forms small rhombic crystals, which have a bitterish taste and an acid reaction, and they are soluble in about 10 times their weight of cold water. This salt, mixed with the quadroxalate, exists in *oxalis acetosella*, and they constitute the compound known by the name of the *salt of sorrel*, employed for removing ink-spots.

Quadroxalate of Potash may be formed by digesting the binoxalate in hydrochloric acid, which taking half the potash, the remainder becomes quadroxalate. The crystals are prismatic, and are as little soluble in water as those of the binoxalate.

The oxalates of potash are all converted by a red heat into carbonate of potash; their composition was first ascertained and pointed out by Dr. Wollaston as affording one of the most remarkable series of proofs of the doctrine of multiple proportions.

Oxalate and Binoxalate of Soda may be formed, but they are not employed.

Oxalate of Lime is a very insoluble compound, and hence oxalic acid and lime, with certain restrictions, are used as tests of each other's presence. Barytes and strontia also form insoluble compounds with oxalic acid. Such metallic ates as are important are noticed under the respective

XALIC ACID, the most highly oxygenated of all the table acids, is also the most rapid and certainly fatal of any which are capable of being crystallized. As the crystals are not unlike those of the sulphate of magnesia, or Epsom salts, mistakes between the two are of very frequent occurrence. Being likewise much used in the arts, and commonly known by the name of *acid of sugar*, it is taken either accidentally, or under the supposition that it is akin to sugar, and therefore pleasant and innocent.

To prevent confusion of the crystals of this formidable acid with those of the sulphate of magnesia, it has been proposed that the former should be coloured while in the course of preparation, an expedient which has not been adopted. But on the other hand, the crystals of Epsom salts have been manufactured of a different shape by a peculiar process of crystallization. The taste is very different, a solution of oxalic acid being intensely sour, while that of sulphate of magnesia is extremely bitter. Attention to this point, in previously tasting a small quantity, may prevent very serious casualties. Oxalic acid not only acts with violence, but produces nearly the same effects to whatever texture of the body it is applied. The concentrated acid, if taken in considerable dose, may cause death in from two to twenty minutes. 'After death the stomach is found to contain black extravasated blood, exactly like blood acted on by oxalic acid out of the body; the inner coat of the stomach is of a cherry-red colour, with streaks of black granular warty extravasation; and in some places the surface of the coat is very brittle and the subjacent stratum gelatinized. Such are the effects of the concentrated acid. When considerably diluted, the phenomena are totally different. When dissolved in twenty parts of water, oxalic acid, like the mineral acids in the same circumstances, ceases to corrode; but, unlike them, it continues a deadly poison, for it causes death by acting indirectly on the brain, spine, and heart. The symptoms then induced vary with the dose. When the quantity is large, the most prominent symptoms are those of palsy of the heart; when less, fits of violent tetanus; and when still less, the spasms are slight or altogether wanting, and death occurs under symptoms of pure narcotism, like those caused by opium.' Very few persons have recovered when the quantity taken was considerable. (Christison *On Poisons*.)

To counteract the very rapid effects of this poison, the most prompt treatment is necessary. Chalk, magnesia, or even the plaster of the room diffused through water, should be given without delay. The other alkalis are improper, as they form soluble salts with the acid, and oxalic acid is an example of a poison which acts through all its soluble chemical combinations. Emetics may be given, if vomiting has not spontaneously taken place; but it is highly inexpedient to give much warm water, as dilution only facilitates the absorption of the poison, and induces its remote but equally fatal effects.

Notwithstanding the formidable properties of this acid, the agreeable cooling effects it displays have led to its employment in the form of lozenges, or in a dilute solution, as a refrigerant. Both in this country formerly, and still in France, it is used to quench thirst, and allay the heat of the stomach, which prevails towards the later stages of consumption. But for this purpose citric acid or lemonade is preferable, as well as safer.

Besides the immediate danger from an over-dose, there is yet a remote source of risk which requires notice. Oxalic acid exists in many vegetables, in combination with lime or potass, or free, as in the case of the cicer arietinum. Many of these plants are used in different parts of the world, as salads, on account of their refrigerating quality. Their frequent employment by persons disposed to calculous diseases is highly dangerous, as they give rise to the formation of the mulberry or oxalate of lime calculus, which is not only the most painful of all the stones found in the human kidneys or bladder, but also the most insidious, for, owing to the insolubility of this compound, no deposit or sediment is observed in the urine at an early period, so as to occasion a suspicion of what is taking place. (Majendie *On Gravel*, 2nd French edit.) [CICER.]

OXALIC ÆTHER is prepared by causing the acid to combine with the æther in its nascent state: for this purpose equal weights of oxalic acid and alcohol are distilled with twice their weight of sulphuric acid. At first alcohol and æther distil, and then oxalic æther, which collects as an oily liquid at the bottom of the receiver: this is to be repeatedly washed with water, and then boiled with litharge till its boiling-point attains 360°: by this the excess of acid is separated); and the oxalic ether, being poured off, is to be redistilled.

The properties of this ether are, that it is of an oily appearance, has an aromatic odour mixed with an alliaceous odour; its specific gravity at 45° is 1·0929, and it boils at 362°. It dissolves sparingly in water, and the solution is neutral to test paper; with alcohol it combines in all proportions: it yields oxalic acid by spontaneous decomposition, and by the alkalies is converted into oxalic acid and alcohol. It is composed of—

One equivalent of oxalic acid . .	36
One equivalent of æther . . .	37
Equivalent	73

OXALIDACEÆ are polypetalous Exogenous plants with a superior ovary, a small number of hypogynous stamens, which are usually monadelphous, and distinct styles. Their fruit contains five cells, in which there are numerous seeds, occasionally expelled with violence by a sudden contraction of the sides of the pericarp. The order is so very nearly allied to Geraniaceæ that it can hardly be considered distinct. The genus Oxalis itself is called Wood-sorrel, from the acidity of the leaves and the natural habitation of the European species in a wild state; it is however most common at the Cape of Good Hope, where the species are extremely ornamental. In the East Indies the genus Averrhoa produces a fruit (the Carambola or Blimbing), used for pickling and preserving; but its extreme acidity renders it intolerable to many persons. Our Oxalis Acetosella, or common Wood-sorrel, has been supposed to be the true Shamrock of the Irish, instead of the trefoil to which the name is more commonly applied. In the tropical parts of India is an annual Oxalis, called *O. sensitiva* in consequence of its pinnated leaves being irritable like the sensitive plant; it has been lately ascertained that the European trefoil-leaved species have the same property, only in a more feeble degree. (*Bulletin de l'Académie Royale de Bruxelles*, vol. vi., No. 12.) This phenomenon is most conspicuous in a hot sunny day.

Oxalidaceæ.

Plant of Oxalis [illegible]: 1, the stamens and styles when the calyx and corolla have been removed; 2, the ovary with the five distinct styles; 3, a transverse section of an ovary.

OXAMIDE, or OXALAMIDE, is obtained by heating oxalate of ammonia in a retort, and also by some other processes. The oxalate of ammonia is decomposed; ammoniacal, carbonic acid, carbonic oxide, and cyanogen gases being evolved: in the neck of the retort, and on the water in the receiver, a dirty white substance is deposited; this is oxamide, which is to be purified by washing with water. Oxamide is composed of—

Two equivalents of carbon . .	12
Two equivalents of oxygen . .	16
Two equivalents of hydrogen . .	2
One equivalent of azote . . .	14
Equivalent	44

It will be seen on examination that it is formed by separating the elements of one equivalent of water = 9 from one equivalent of oxalate of ammonia = 53. Although it contains neither oxalic acid nor ammonia, yet, when boiled with a solution of potash, ammonia is evolved, and oxalate of potash formed; it appears therefore that it resumes oxygen and hydrogen by decomposing water, owing to the influence of the alkali. With sulphuric acid corresponding results are obtained; carbonic acid and carbonic oxide gases are evolved, and sulphate of ammonia is formed.

The properties of oxamide are, that it is inodorous, insipid, insoluble in cold water; but boiling water dissolves it, and on cooling, flocculent crystals of a dirty white colour are deposited. When moderately heated, it sublimes unchanged; but when quickly heated, it is decomposed, yielding cyanogen gas and a bulky sooty residue. Dilute acids do not alter it, but with strong acids it suffers the change already described.

The production of this substance, and the reproduction of oxalic acid and ammonia, have given rise to some general views which have been embodied by Dumas. (*Théorie des Amides; Chimie appliquée aux Arts*, t. v., p. 64.)

OXENSTIERNA, AXEL, COUNT, born in 1583, of a noble Swedish family, studied in Germany at Rostock, Jena, and Wittenberg, in which last university he took degrees. After his return to Sweden, he followed the career of diplomacy under Charles IX., and was made a senator. When Gustavus Adolphus ascended the throne in 1611, he appointed Oxenstierna chancellor or prime minister. From that time the name of the minister is closely connected with that of his illustrious master, whose confidence he fully enjoyed, and to whom his abilities as a statesman were of the greatest service. After the death of Gustavus, at the battle of Lützen, in 1632, Oxenstierna, who was then on a mission in another part of Germany, immediately repaired to the camp, concentrated the Swedish and allied forces, urged the German princes to remain steady in the cause of the alliance against the political and religious tyranny of the emperor Ferdinand, and having received full powers from the senate of Sweden, he became the soul of the Protestant league in Germany. The difficulties which Oxenstierna had to encounter proceeded from the jealousy of his allies more than from the efforts of the enemy. He succeeded however in assembling the States of Lower Saxony at Heilbronn, and he opened the meeting by a speech. After much opposition, he obtained a supply of money for the Swedish army, and he was himself acknowledged as the head of the league. A succession of able commanders, the Duke of Weimar, Banner, Torstenson, Wrangel, all formed in the school of Gustavus, led on the Swedish and German forces with various success, while Oxenstierna directed from Stockholm the diplomatic negotiations, until the peace of Westphalia, in 1648, put an end to the Thirty Years' War. Count Oxenstierna's son was one of the Swedish envoys who signed that celebrated treaty. It was to him that the chancellor, in reply to the young man's letters, in which he had expressed himself with great diffidence in consequence of his inexperience in matters of state, wrote the following sentence, which has become proverbial: 'Nescis, mi fili, quantillâ prudentiâ homines regantur' (You do not know yet, my son, how little wisdom is exhibited in ruling mankind).

Oxenstierna was at the head of the regency of Sweden during the whole minority of Queen Christina, and he continued to be prime minister after she had assumed the reins of government. He strongly opposed Christina's intention of abdicating the crown, and being unable to prevent this act, he withdrew from public life. Christina's successor, Charles Gustavus, consulted him however on important occasions. Oxenstierna died at Stockholm, in August, 1654, regretted and honoured by all Sweden. He is said to have been partly the writer of the 'Historia Belli Sueco-Germanici,' published by Chemnitz, and also of the work 'De Arcanis Austriacæ Domus ab Hippolyto à Lapide.'

OXFORD, City. [OXFORDSHIRE.]

OXFORD, Bishopric. [OXFORDSHIRE.]

OXFORD UNIVERSITY. The origin of the University of Oxford is unknown. It is agreed upon among the ablest investigators that, although this University may be traced to very high antiquity, and beyond the age of any satisfactory records, the illustrious Saxon king, who is generally said to have founded or restored it, really did nothing of the kind. No document or well-authenticated history can be produced in which the name of Alfred appears as a benefactor to this University. It is certain however that Oxford was a place of study in the reign of Edward the Confessor, if not earlier.

The first places of education in Oxford appear to have been schools for the instruction of youth. These schools were either claustral, that is, appendages to convents and other religious houses; or secular, such as were kept by, or hired and rented of, the inhabitants of Oxford. When many of these secular scholars resided in one house, it got the name of Hall or Hostel (terms which are not yet out of use), and governors or principals were appointed to superintend the discipline and the affairs of the house. But it does not appear in what respects the education in these halls differed from that in religious houses, which were the oldest places of instruction. The schools were divided into grammar-schools, sophistry-schools, schools for arts, medicine or physic schools, law-schools, divinity-schools, &c. It is difficult to discover any traces of a regular plan of education in Oxford before the foundation of the first college by Walter de Merton. The statutes of this founder for his college are well digested: and they have been adapted with little alteration to succeeding times in other colleges as well as his.

A remarkable fact in the early history of Oxford has only been put in a clear light of late years, and that by the industry of German scholars. In the reign of King Stephen, Vacarius, a Lombard by birth, established a school of Roman law at Oxford. Stephen after a time attempted to suppress all instruction in the Roman law, but we are informed that his attempt was not successful. It is not stated how it happened that the school of Roman law was still maintained; but it was not put down at once, and it appears very probable that it subsisted for some time after the death of Vacarius. The pupils of Vacarius were numerous, and as many of them were poor, he prepared for their use (about the year 1149) a work on Roman law in nine books, which was extracted from the Pandects and the Code. The learned John of Salisbury was the friend of Vacarius, and though Roman jurisprudence was only one of his numerous studies, and not the chief of them, he was competently acquainted with Roman law, and doubtless indebted for his acquaintance with it to the Oxford school of Vacarius. (Savigny, *Geschichte des Römischen Rechts im Mittelalter*, 4er band; Wenck, *Magister Vacarius*, Lips., 1820.) [VACARIUS.]

Various accounts are given of the number of students at Oxford in the reigns of the early Norman kings. In the time of Henry III., we are told by Wood in his Annals (vol. i., p. 266) that they amounted to thirty thousand; and even when Merton College was founded, they are said to have amounted to fifteen thousand. (Gul. Rishanger, in Chron. suo MS. Bibl. Cott., Claud., D. vi., quoted by Wood, ut supra, p. 266.) But these numbers are evidently great exaggerations, and it is not easy to see how any writers could be led to make statements so grossly improbable. Still there is no doubt that the University was then frequented by a great number of students, and many foreigners resorted to it from Paris and other places.

The earliest charter of privileges to the University of Oxford as a corporate body is of the 28th Hen. III. (Pat. 28 Hen. III., m. 6, 'Libertates concessæ Cancellario Universitatis Oxon.') It was followed by charters, some of fresh privileges, and others of general confirmation of the privileges formerly granted, in the 39th Hen. III., A.D. 1255; in the 18th Edw. III., 1344; in the 17th and 33rd Edw. III.; in the 1st Hen. V.; 37th Hen. VI.; and 15th Hen. VIII. The last confirmation was in the 13th Elizabeth, in the 'Act concerning the several Incorporations of the Universities of Oxford and Cambridge, and the confirmation of the Charters, Liberties, and Privileges granted to either of them.'

The Cottonian MS. in the British Museum, Claud., D. viii., contains an ancient copy of the statutes, privileges, and customs of this University, upon vellum, written early in the fifteenth century, a beautiful manuscript. Another MS. in the same collection, Faustina, C. vii., contains an enumeration of the titles of all the charters granted to the University, whether of general or individual privilege, from the time of Henry III. to 1591, which are very numerous.

The regulation of the assise of bread and beer, and the supervision of weights and measures, were granted to the chancellor of the University by Pat. 32 Edw. III., m. 5.

The same jealousy of the authority of the University which existed in early times among the townsmen of Cambridge, prevailed at Oxford also. The quarrels between the scholars and the townsmen often broke out into open violence, sometimes accompanied with bloodshed. Matthew Paris makes mention of these riots as early as 1240. (See also Wood's *Annals of the Univ.*, vol. i., pp. 231, 237, 263, 367, 412, 456.) On several occasions the scholars quitted the University for a time. At one period they retired to Northampton, at another to Stamford. The most serious riot on record was on the day of St. Scholastica the Virgin, Feb. 10th, 1354-5, when many lives were lost. Grosteste, bishop of Lincoln, in whose diocese the University then was, placed the townsmen under an interdict, from which he released them in 1357, upon condition that the commonalty of Oxford, every year after, should celebrate an anniversary on St. Scholastica's day, in St. Mary's Church, for the souls of the clerks and others killed in the conflict; and that the mayor for the time being, the two bailiffs, and three score of the chiefest burghers, should personally appear on the said day in St. Mary's Church at mass, and offer at the great altar a penny each. The mayor and commonalty at the same time gave a bond to pay a hundred marks yearly to the University, as a compensation for the great losses occasioned by the fray; but the bond was not to be enforced so long as the mayor and sixty-two burghers came yearly and performed the penance. This bond was recited and confirmed in a charter of inspeximus by King Edward III. (Pat. 31 Edw. III., p. i., m. 26.) After the Reformation, this custom having been neglected in the beginning of Queen Elizabeth's reign for fifteen years, the University sued the city for fifteen hundred marks. The citizens answered, that their penalty was in the bond of a mass, which was against law. The lords of the queen's council however, before whom the case was finally brought, in her seventeenth year, having discharged the city from the arrears, ordered that in future the same number of citizens should, on St. Scholastica's day, attend a sermon or communion at St. Mary's, offering each a penny at the least. This was subsequently changed to attending at the ordinary church service: the offering was made immediately after the Litany, which, for that purpose, was read at the altar. It continued, with now and then an intermission (the citizens being always anxious to get rid of this penance), till 1825, in which year, on Feb. 1st, in full convocation, the University seal was affixed to an instrument which entirely released them from its observance.

This University has been long governed by statutes, or bye-laws, made at different times, and confirmed by the charters of the kings of England. Those at present in force were drawn up in 1629, and confirmed by a charter from King Charles I., in 1635. The corporation of the University is styled 'the chancellor, masters, and scholars of the University of Oxford.'

The highest officer is the chancellor. In the thirteenth century the chancellor was styled the master or rector of the schools, and appears to have derived his authority from the bishops of Lincoln, who were then the diocesans of Oxford. The bishops confirmed, while the regents and non-regents nominated, the chancellor; but after the reign of Edward III., the chancellor was elected and confirmed by the regents and non-regents only. At first the election was for one, two, or three years; but afterwards for life. Still however the person chosen was a resident member of the University, and always an ecclesiastic until the time of Sir John Mason, in 1553, who was the first lay-chancellor. It was afterwards conferred, at the pleasure of the convocation, upon ecclesiastics or laymen. Since the time of Archbishop Sheldon, in 1667, it has only been conferred upon noblemen of distinction who have been members of the University.

The chancellor's deputy was formerly styled vicegerent or commissary, but for a long time past he has been styled vice-chancellor. His office is annual, though generally held for four years. The vice-chancellor is nominated by the chancellor, on the recommendation of the heads of colleges, and appoints four deputies, or pro-vice-chancellors, who must likewise be heads of colleges. During the vacancy of chancellor however, the office is executed by the senior theologus, or cancellarius notus, resident in the University.

The seneschallus, or high steward, is appointed by the chancellor, and approved by convocation. The office is for life. The high steward assists the chancellor, vice-chancellor, and proctors in the execution of their respective [illegible] and defends the rights, customs, and liberties of the University. If required by the chancellor, he hears and determines capital causes, according to the laws of the land and the privileges of the University, whenever a scholar or privileged person is the party offending. He also holds the University court-leet at the appointment of the chancellor or vice-chancellor, either by himself or deputy.

The office of proctor is supposed to be coeval with that of chancellor. The duty of the two proctors is to inspect the conduct of the members of the University as to all matters of discipline and good order; they are in fact the acting magistrates. They must be masters of arts, of not less than four years' standing, and chosen out of the several colleges by turns according to a cycle framed in 1629 by Sir Peter Turner, Savilian professor, and Robert Heggs of Corpus College, and sanctioned by the statutes given by Charles I. at that time. After their election they nominate four masters of arts to be their deputies or pro-proctors, and may depute their authority to a larger number if necessary.

The whole business of the University is transacted in two distinct assemblies, termed 'Houses,' namely, the House of Congregation and the House of Convocation. The chancellor, or vice-chancellor, or, in his absence, one of his four deputies, and the two proctors, or, in their absence, their respective deputies, preside in both houses, where their presence is necessary on all occasions.

The business of congregation is principally confined to the passing of graces and dispensations, and to the granting of degrees. Upon all questions submitted to that house, the vice-chancellor singly, and the two proctors jointly, have an absolute negative. In the sole instance of supplicating for graces, but in no other, every member of the house, in addition to his general right of suffrage, has a suspending negative upon each grace for three times, as the grace is proposed in three distinct congregations; but previously to the fourth supplication, he is required to state privately to the vice-chancellor and proctors the ground and proof of his objection, which are submitted to the judgment of the House for approbation or rejection. All suffrages for or against graces and dispensations in congregation are to be whispered secretly into the ear of the proctor, by a majority of which, given in the words *placet* or *non placet*, the fate of the measure is ultimately determined.

The power of convocation extends to all subjects which are connected with the affairs of the University. In the exercise however of one particular branch of its privileges, the enacting of new or the explaining of old statutes, some restriction is imposed. If the statute to be explained be a royal, or, as it is commonly called, a Caroline statute,* the royal permission is first to be obtained. If it be deemed advisable to enact *de novo*, or to explain any except a royal statute, the measure must be referred to the hebdomadal meeting of the heads of houses; and if this meeting, on deliberation, approve of the measure, it draws up the terms in which it is to be promulgated in the House of Congregation, and, three days after, proposed in convocation.

As in congregation, so also in convocation, the chancellor or vice-chancellor singly, and the two proctors jointly, are severally invested with an absolute negative upon all proceedings except in elections.

In both Houses, when the negative of the vice-chancellor, or of the proctors, is not interposed (an interposition almost as rare as the royal veto in parliament), every question is decided by the majority.

For the better government of the University, there is also an hebdomadal meeting of the heads of houses, who meet every Monday, and at other times when convened by the vice-chancellor. This meeting consists of the vice-chancellor, heads of houses, and proctors, who deliberate upon all matters relating to the privileges and liberties of the University, and inquire into and consult respecting the due observance of statutes and customs. All the letters likewise of the chancellor, in the case of dispensations, which are addressed to convocation, must be sanctioned by them before they are recited in the House.

In 1603 King James I., by diploma dated March 12th, granted to the Universities of Oxford and Cambridge the privilege of choosing two representatives in parliament. This measure was opposed by the House of Commons, but ably supported by Sir Edward Coke. The members are chosen by the vice-chancellor, doctors, and regent and non-regent masters in convocation.

The following are the colleges of Oxford, with the dates of their respective foundations:—University College, said to have been founded in 872; restored before 1249. Merton, founded at Malden, in Surrey, in 1264; removed to Oxford, 1274; Exeter, 1314; Oriel, 1326; Queen's College, 1340; New College, 1386; Lincoln, 1427; All Souls, 1437; Magdalen, 1456; Brasenose, 1490; Corpus Christi College, 1516; Christ-Church, 1525; Trinity, 1554; St. John's College, 1555; Jesus College, 1571; Wadham, 1613; Pembroke College, 1624; Worcester, 1714; St. Edmund Hall, soon after 1269; St. Mary Hall, 1333; New Inn Hall, 1392; Magdalen Hall, 1487; St. Alban's Hall, soon after 1547. It may not be unnecessary to remark that the colleges are corporate bodies belonging to the class called *eleemosynary* [COLLEGES], and are quite distinct from the corporation of the University, with which, in the common opinion, they are often confounded; a mistake which the dicta of eminent judges (Lord Mansfield for instance), and still more the actual mode of administering the affairs of the University at present, has chiefly contributed to create and maintain. [UNIVERSITY COLLEGE, &c.]

The buildings belonging to the University of Oxford are:—

1. The *Schools*, with the *Bodleian Library*. The Divinity School, with the room above forming part of the Bodleian, was completed about the year 1480: the rest of the Schools, with the remainder of the Bodleian, early in the seventeenth century, by Thomas Holt, of York, who is supposed to have been the architect of Wadham College, and of the new quadrangle of Merton, both built about the same time. The Bodleian Library was first laid open to the public on Nov. 8th, 1602. Attached to it is the picture-gallery of the University.

2. The *Theatre*, built by Gilbert Sheldon, archbishop of Canterbury and chancellor of the University, in 1669, at the expense of fifteen thousand pounds. The upper part of this building was used for the University press till 1713.

3. The *Ashmolean Museum*, built at the charge of the University in 1683.

4. The *Clarendon*, completed in 1712, partly from the profits arising from the sale of Lord Chancellor Clarendon's 'History of the Rebellion,' the copyright of which was given to the University. The printing for the University was carried on in this building from 1713 to 1830, when it was removed to the newly-erected printing-house. The basement-story of the Clarendon contains at present a police-room, and other apartments connected with that establishment; the remainder of the building is appropriated to offices for the despatch of University business, and lecture-rooms for the professor of experimental philosophy and the readers in mineralogy and geology.

5. *Radcliffe's Library*.—The munificent founder of this library was John Radcliffe, M.D., who was born at Wakefield in 1650. By his will, 13th September, 1714, he appropriated 40,000*l*. for the building and purchase of the ground on which it stands; 100*l*. per annum for the purchase of books, and 150*l*. per annum for the librarian. James Gibbs, a native of Aberdeen, was the architect. The foundation-stone was laid June 16, 1737, and the building was completed in 1747. This library was opened April 13, 1749, in a public ceremony by the trustees of Dr. Radcliffe's will. It has been appropriated by a late resolution of the trustees to the reception of books in medicine and natural history. In the area of this library a few antique marbles are deposited, with a selection of casts from the best statues of antiquity. Here also is preserved the Corsi collection of specimens of the marbles employed in the ornamental architecture of both antient and modern Rome.

6. *The Radcliffe Observatory*.—This building was erected out of the funds of Dr. Radcliffe by the trustees of his will. It comprises a dwelling-house for the observer, apartments for observation and lectures, as well as rooms for an assistant-observer, and it is amply supplied with astronomical instruments. The foundation-stone was laid June 27, 1772. The original architect was Mr. H. Keene. The building was altered and completed by Mr. James Wyatt. The Radcliffe trustees appoint the observer, who nominates his assistant.

7. *The University Press*.—As the great increase of busi-

---

* These statutes transmitted by Charles I., and confirmed by convocation, [illegible]

ness rendered it necessary to have more extensive premises, the delegates of the press were empowered by convocation, in 1825, to contract for the purchase of ground north of Worcester College, for the erection of a new building. The present building was commenced in 1826, from a design made by Mr. Daniel Robertson. The entire front and the south wing were finished in 1827; the north, which was commenced in 1829 under the superintendence of Mr. Blore, was completed in the following year; and on the west side of the quadrangle are houses for the superintendents, an engine-house, strong-room for standing type, &c.

Beside these buildings, there is a *Botanic Garden*, containing about five acres, originally the burial ground of the Jews in Oxford. The entrance gateway, designed by Inigo Jones and executed by Nicholas Stone, is decorated with a bust of the founder, Henry Danvers, earl of Danby, by whom these premises were purchased and improved at an expence of 5000*l*. in 1632.

The Professors of the University are, like those of Cambridge, paid from various sources; some from the University chest, others by the king, or from estates left for that purpose. They are—the regius professors of divinity, civil law, medicine, Hebrew, and Greek, upon the foundation of King Henry VIII.; the Lady Margaret's professor of divinity; the Savilian professors of geometry and astronomy; Dr. White's professor of moral philosophy; the Camden professor of antient history; Tomline's prælector in anatomy; a professor of music; two professors of Arabic, one of whom is called the Lord Almoner's Reader; a botanical professor; a professor of poetry; a regius professor of modern history and modern languages, founded by King George II. in 1724; an Anglo-Saxon professor; the Vinerian professor of common law; a clinical professor; the Aldrichian professors of anatomy, of the practice of medicine, and of chemistry; a professor of political economy; a professor of Sanscrit; Lee's lecturer in anatomy; and readers established by grant from the crown, in experimental philosophy, in mineralogy, and in geology. Several of these professors give no lectures; a circumstance which is explained by the fact of some of the antient studies of the University having fallen into disuse, civil law for instance; but more particularly in consequence of the practical change which in the course of time has taken place in the system of teaching. The instruction is now given to the undergraduates by their tutors in the respective colleges, and the University merely determines the course of instruction and superintends and directs the examinations which it requires the students to submit to as a preliminary to the attainment of a degree.

The total number of members upon the books of the different colleges and halls of Oxford, at the end of 1839, was 5440.

(Wood's *Annals of the University*, edited by Gutch; Chalmers's *History of the Colleges, Halls, &c. of Oxford*, 2 vols. 8vo., 1810; Oxford *Univ. Calendar*, to which last work the reader is referred for more particular information on the existing state of the University, its scholarships, examinations, prizes, &c.)

OXFORD, EARL OF. [HARLEY.]

OXFORDSHIRE, a midland county of England, bounded on the north-east by Northamptonshire, on the east by Buckinghamshire; on the south-east, south, and south-west by Berkshire; on the west by Gloucestershire, and on the north-west by Warwickshire. Its figure is very irregular: the greatest length is from north by west to south by east, from the three shire-stones at the junction of the three counties of Northampton, Warwick, and Oxford, to the junction of the Kennet with the Thames, near Reading in Berkshire, 51 miles: its breadth is very variable: in the northern part, from the neighbourhood of Burford to the banks of the Ouse near Buckingham, it is 32 miles; but to the north of Oxford city the breadth contracts suddenly to about 7 miles; and in the southern part of the county it never exceeds 16 miles, and has that breadth only for a short space, between Abingdon and Thame. The area is estimated at 756 square miles: it is in size the thirty-first of the English counties, being rather smaller than Surrey, but larger than Berkshire. The population, in 1821, was 136,971; in 1831 it was 152,156; showing an increase in ten years of 15,185, or more than 11 per cent., and giving 201 inhabitants to a square mile: in amount of population it is the thirtieth of English counties; in density of population, the twentieth. Oxford, the shire town, is at the junction of the Charwell with the Isis or Thames, 51 miles from London (St. Paul's) in a straight line west-north-west; 57 miles from the General Post-office, which is close to St. Paul's, by the Ludlow and Worcester mail-road through Uxbridge, Beaconsfield, and High Wycombe; or 60 miles by the Caermarthen and Gloucester mail-road, through Hounslow, Colnbrook, Maidenhead, and Henley.

Surface and Geological Character.—The southern part of the county is occupied by the Chiltern Hills, which extend across the southern extremity from Buckinghamshire on the east to Berkshire on the south-west. These hills are composed of chalk, and form part of that extensive range of chalky elevations which extends through the counties intervening between Norfolk and Wiltshire, and which encloses on that side the chalk basin of London. The outer or north-western escarpment of those hills, which is the steep side, crosses the county from north-east to south-west, near Stokenchurch, Nuffield, and Checkindon or Chalkenden. This escarpment is known on the eastern side of the county as Stokenchurch Hill. On the western side, on the summit, is Nuffield Common, which has an elevation of 757 feet. Nettlebed Hill, near Nuffield Common, is 820 feet high. The Thames flows through a winding valley or depression traversing this chalk range. The Chilterns were formerly occupied by a forest or thicket of beech trees, which are the trees best adapted to the soil. There are still several beech woods or plantations, though a large part of the surface is now occupied as arable land or as sheep-walks.

From the foot of these hills the lower formations of the cretaceous group crop out. The upper green-sand scarcely appears, being almost lost in the chalk marl which overlies and in the gault which underlies it: the gault has been sometimes designated Tetsworth blue marl or Tetsworth clay, from the village of Tetsworth near Thame, or (from its suitableness to the growth of the oak) 'oak-tree soil.' The iron-sand or lower green-sand crops out from beneath the gault, and with its subordinate beds of ochre is found covering to the depth of 50 feet the upper oolitic formations on the summit of Shotover Hill, which hill has an elevation of 599 feet.

The upper division of the oolitic series, comprehending the Purbeck, Portland, and Kimmeridge beds, crops out from beneath the iron-sand. These oolites rise to their highest point in this county in Shotover Hill, on the summit of which they are covered by the iron-sand and ochre. These beds are quarried at Garsington, not far from Oxford, on the south-west of Shotover Hill.

The surface occupied by these formations from the chalk marl inclusive forms an undulating tract without any lofty hills: each group of formations occupies a strip of surface of varying breadth, extending from north-east to south-west across that narrow part of the county which lies south of Oxford. The Kimmeridge clay does not appear on the east of Shotover Hill.

In the immediate neighbourhood of Oxford, to the east of that city, the coral rag, one of the formations of the middle division of oolites, forms an elevated platform between the valleys of the Charwell and the Thame. Beckley, on the northern edge of this platform, is its most elevated point: on the southern side it gradually subsides, the strata dipping in that direction. This formation is not found on the eastern side of the county, but on the western side it extends across the Thames into Berkshire: the Thames flows through what appears to be a breach formed by subsequent denudation in this range. The blue clay or Oxford clay, which forms the lowest member of the middle oolite group, separating the coral rag from the lower oolites, crops out from beneath the coral rag, and occupies the middle part of the county as far as Bicester, Woodstock, Witney, and Bampton, near which towns the line of junction between this and the subjacent formations may be traced. The tract occupied by the Oxford clay is for the most part low and flat. It forms the valley of the Isis or Thames above Oxford. On the eastern side of the county the Portland beds of the upper series of oolites rest immediately on the Oxford clay, the intermediate formations not being found.

The rest of the county, except the valley of the Charwell, from the neighbourhood of Banbury upward, is occupied by the lower division of the oolites. The upper beds of this division, which are probably cornbrash beds, are often of a pasty or chalky consistency and colour. The forest marble, another formation of this division, has obtained its name from Wichwood forest near Burford, where it is found. It is a limestone, susceptible of a tolerable polish, and occausually used as a coarse marble. It consists of thin slaty beds, seldom having a thickness of two or three feet, and parted by layers of clay varying in thickness from less than an inch to a foot. The calcareous slate of Stonesfield near Woodstock probably belongs to the same part of the series as the forest marble: it is remarkable for the singular variety of its organic remains, among which are the spoils of birds, land animals, amphibia, sea shells, and vegetables. The slate consists of two fissile beds of buff or grey oolitic limestone called 'pendle:' each bed is about two feet thick, and is separated by a bed of loose calcareo-siliceous sandstone called 'race.' The pendle, after being quarried, is exposed to the action of a winter's frosts; and the blocks, being struck on their edge with a mallet, freely separate into slates sufficiently thin to afford a light material for roofing. The quarries are in the valley of the Evenlode, near the village of Stonesfield, not far from Blenheim: they have been wrought from a remote period, and give employment at present to many labourers. The great oolite is quarried near Burford; and these quarries supplied the stone of which St. Paul's Cathedral (London) is built.

The lower division of the oolites form the mass of a well-defined range of hills rising from the valley occupied by the Oxford clay. The cornbrash is generally found on the first acclivity, rising above the valley; the forest marble and calcareous slate crop out from beneath the cornbrash, and form the slope above it; and the great oolite, emerging from beneath these, forms the highest part of the hills. In extensive districts however, both in Oxfordshire and in the adjacent county of Northampton, some causes have led to the denudation of the cap of the great oolite in several places, causing it to terminate on the north-west in a low terrace, and exposing the subjacent beds of ferruginous sands and sandstone. Numerous insulated masses of the great oolite are scattered throughout the space thus denuded, sometimes forming the caps of hills, and in the regular plane of the strata, at other times forming extensive masses in the valleys or low grounds, surrounded by sandy hills and disposed in considerably inclined planes, thus appearing as if they had been precipitated, perhaps by waters undermining the subjacent sandy beds, into their present situation. The denuded parts occupied by the ferruginous sands extend over the greater part of the county north of Deddington and Chipping-Norton, and occupy the greater part of the valley of the Evenlode. Between the great oolite and these sandy and sandstone beds a thick clay is generally found; and beneath the sands is found a sandy, gritty, micaceous marl, generally deriving a green colour from a copious admixture of silicate of iron, and containing beds of gritstone, some of which are decomposed by exposure to the atmosphere, while others are much harder, and are quarried for flagstones, troughs, and other coarse purposes. The district occupied by these oolitic and arenaceous formations contains some of the highest hills in the county. Epwell Hill, near the border of this county and Warwickshire, is 836 feet high. Edge Hill is close to the border, but just within Warwickshire.

The lias beds, which underlie the oolites, rise to the surface in the valley of the Charwell on the north-eastern border of the county, and again in a projecting portion on the north-western border near Chipping-Norton; but the extent of country occupied by them is very trifling.

Hydrography and Communications.—Oxfordshire is almost entirely comprehended in the basin of the Thames. The Stour, an affluent of the Warwickshire Avon, rises just within the north-western boundary; and the Ouse, in the upper part of its course, skirts the north-eastern boundary, and receives one of its smaller tributaries from that part of the county; but the districts watered by these streams are too small to require further notice.

The Thames, or, as it is sometimes called in the upper part of its course, the Isis, first touches the county a little below Lechlade in Gloucestershire, at which town the navigation commences. From below Lechlade it flows along the border between Berkshire and Oxfordshire, until it finally quits the latter county a little below Henley. The length of this part of its course may be estimated at about 71 miles. Its course from Lechlade is easterly to below the junction of the Windrush; then north-north-east to below the junction of the Evenlode; from thence south-south-east, though with many windings, past Oxford, where it receives the Charwell, Abingdon in Berkshire, where it receives the Ock, Dorchester, where it receives the Thame, and Wallingford in Berkshire, to the junction of the Kennet near Reading in Berkshire: below the junction of the Kennet its course is first north-east then north-west to Henley, just below which it leaves Oxfordshire altogether.

The Windrush, Evenlode, Charwell, and Thame belong chiefly to Oxfordshire. The Windrush rises in the Cotswold Hills, on the border of Worcestershire and Gloucestershire, and after flowing about 15 or 16 miles through the latter county, enters Oxfordshire, through which it has a further course of about the same length (making 32 to 36 miles in all), passing Burford and Witney into the Thames, into which it flows by several channels. It is not navigable, but turns many mills.

The Evenlode rises near Moreton-in-the-Marsh in Gloucestershire, and enters Oxfordshire about 9 miles from its source, having previously skirted the border for a short distance: its course through Oxfordshire may be computed at 22 miles, making about 31 altogether. It passes Charlbury. It receives several small tributaries; one (7 miles long) from Great Rollwright near Chipping-Norton, just as it enters the county, and one (the Glyme, 12 miles long) also from the neighbourhood of Chipping-Norton. The Glyme passes Woodstock and flows through Blenheim Park, where it expands into a large sheet of water. Neither the Evenlode nor any of its tributaries is navigable, but they turn many mills.

The Charwell rises near the village of Charwelton in Northamptonshire, and flows southward into the Thames. About 2 miles from its source it enters Oxfordshire near the northern extremity of that county, and has a farther course of about 37 miles (making 39 altogether) past Banbury to Oxford, where it joins the Thames; part of this course is on the border of Oxfordshire and Northamptonshire. It receives a number of small tributaries, the principal of which are the Sorbrook from the border of Warwickshire, and the Ray from the neighbourhood of Bicester. The Charwell is not navigable: there are many mills both on the river and its tributaries.

The Thame rises at Stewkley, between Aylesbury and Fenny-Stratford in Buckinghamshire, and flows south-west 17 *or* 18 miles to the town of Thame, where it touches the border of Oxfordshire: for about 5 miles farther it skirts the border, and then entering the county flows through it about 10 miles (making 32 *or* 33 miles altogether) into the Thames at Dorchester. It is navigable from Thame to Dorchester, 13 miles.

The Oxford Canal, the only one in the county, commences at Longford in Warwickshire, between Coventry and Nuneaton, where it unites with the Coventry Canal, 313½ feet above the level of the sea. It enters Oxfordshire near the northern extremity of the county, some miles north of Banbury, and follows the valley of the Charwell southward to Oxford, where it terminates in the Thames, 192 feet above the level of the sea. The first act for making this canal was passed A.D. 1769; the last act relating to it was passed in 1829. This canal forms part of one main line of inland navigation between London and the manufacturing towns of the midland iron district, Birmingham, Wolverhampton, &c.; also between London and Manchester and Liverpool. An immense quantity of coal is conveyed by it from the Warwickshire and South Staffordshire coal-fields to Oxford and other towns on the Thames.

The principal roads are from London to Oxford, and from thence to Gloucester, Worcester, and Birmingham. The road travelled by the Caermarthen and Gloucester mail enters the county at Henley-upon-Thames, and runs by Nettlebed, Bensington, and Dorchester to Oxford, and from thence by Witney and Burford into Gloucestershire. That traversed by the Ludlow and Worcester mail enters the county near Stokenchurch, and runs by Tetsworth and Shotover to Oxford, and from thence by Woodstock and Chipping-Norton to Moreton-in-the-Marsh, Gloucestershire. The road travelled by the Stroud mail branches off from the Caermarthen and Gloucester mail-road at Dorchester, and runs to Abingdon, just before entering which it crosses the Thames and quits the county. The road travelled by the Birmingham mail, before the formation of the rail-road, enters the county between Aylesbury and Bicester, and runs by Bicester and Banbury into Warwickshire. There are no rail-roads in Oxfordshire. The London and Birmingham line passes several miles to the north of it through Northamptonshire and Warwickshire.

Agriculture.—The climate of this county is, on the whole, colder than its situation in the central part of the island would lead one to expect. The hilly lands in the north-western part are exposed and bleak; and the influence of the winds is only partially checked by the low stone-walls which form the usual boundaries of the fields. The poorer chalky soils also on the slopes of the Chiltern Hills are late in bringing crops to maturity. But notwithstanding this circumstance, the county may be reckoned amongst the most productive agricultural counties of England; and some of the land is of a quality which can scarcely be surpassed anywhere.

The soil may be divided into four distinct classes:—the rich red loam, the *stonebrash*, the chalky, and the irregular loams; and sands and gravels, which cannot be classed with any of the foregoing. Arthur Young, in his Report of Oxfordshire, states the proportions of these soils as follows:—

Red land	79,635	acres.
Stonebrash	164,023	„
Chiltern chalk	64,778	„
Miscellaneous	166,400	„
Total	474,836	acres.

The red land is partly in old grass, in which state it is very valuable, and partly cultivated as arable land. A great portion of this division was formerly disposed in common fields and consequently poorly cultivated. The enclosure and division of these lands have, in many cases, doubled their annual produce. A finer tract of land than this red loam is scarcely to be found. It is neither heavy nor light, wet nor dry, but easily worked at all times; and the crops, with a very slight attention to the cultivation, amply repay the farmer for his trouble and outlay. The land lets at a high rent, but the tenant can well afford it, his crops being certain, and almost always very abundant.

The stonebrash district, which extends from the borders of Gloucestershire across the country to the north of Oxford and Whitney, is of inferior fertility to the red land; but it is easily worked, and, having a porous subsoil, is not often injured by rain. The soil is formed of decomposed stone, chiefly chalk and sandstone. The subsoil is generally porous. Very fine marl is frequently found at a small depth under the surface; and where the soil is of a light quality with little cohesion, the application of marl is highly advantageous.

The chalk district is in the south-eastern portion of the county. The chalk is generally covered to a certain depth with a light calcareous loam, evidently produced by the decomposition of the chalk and the mixture of organic matter in a state of decay. Flints of various shapes are mixed up with the loam, and in some places are supposed to be essential to the fertility. The low lands in the valleys through which the rivers flow are in many places covered with the finest herbage, and maintain much cattle. A part also is cultivated as arable land, and in the hands of regular gardeners would make excellent market-gardens; as it is, it produces great crops of barley, clover, beans, and wheat, and, when properly managed, heavy crops of turnips.

Besides these distinct soils, there are many of a mixed nature varying in texture and quality without any regularity. Where they are incumbent on a porous subsoil, they are mostly fertile. Some few consist of poor sands or wet clays, which form the extremes, and are very unproductive until they are corrected and improved by marling or draining.

The land in this county, as in many others, was formerly ploughed in high broad ridges, wherever the moisture could not readily sink through the subsoil. These ridges, so often described, were made by repeatedly ploughing towards the same line in the middle of the ridge. All the good soil was thus accumulated in the crown, and the deep furrows between the ridges were completely stripped to the subsoil. The consequence was, that much good soil was buried, and half the surface produced little or nothing. It was not an easy task to correct this and to lay the lands into neat and moderate stitches, so that the crown and furrow might alternately occupy the same line. It took some time to undo what many years had been employed in effecting, and some caution was required not to proceed too rashly in this reform. If the good soil of the crown were buried at once in the deep furrows in order to level the surface, the crops would be very deficient. The only rational plan is to proceed slowly, forming a narrow stitch in the old furrows and gradually widening it and raising it, till the old high stitch is divided into two moderate ones. Where the subsoil is porous or the land has been efficiently underdrained, it may be ploughed flat without risk or danger, and the crop will be better and more equal.

The implements of husbandry now in common use in Oxfordshire are greatly improved. The old plough with a straight wooden turn-furrow and a pair of wheels in front, which, with four horses, scarcely ploughed three-quarters of an acre in a summer's day, is now seldom met with. But more horses are still used than strict economy would warrant, and the time occupied in labour is seldom more than seven or at most eight hours in the day, except in harvest. The walk of the horses and men is sluggish.

Threshing-machines have been erected on many of the larger farms, but, from the great outcry against them, they are not in general use at this time on moderate-sized farms. The farmers prefer allowing their men to thresh by the task, as it keeps up a habit of industry and prevents their becoming idle when other work is slack. But if the time lost in threshing by the flail were applied to draining, marling, or burning the soil, the increased crops would soon show whether machinery employed in husbandry to lessen manual labour be profitable or not.

Improved implements, such as scarifiers, grubbers, and drilling-machines, of various constructions, are used in most districts, having been introduced by some spirited proprietor or extensive farmer. If they are not always found so useful as the inventors of them would wish the farmers to believe, they excite reflections and comparisons which tend greatly to the improvement of the old mode of cultivation and to the economy of labour.

There are some large estates in the county, the property of noblemen and men of fortune, and a considerable portion of the county belongs to ecclesiastical and other corporations. These last, being let for terms of years or lives renewable at different periods, are not in general so well cultivated or so highly improved as where the leases are more certain. Short leases with restrictive clauses are common in some parts of the county, but these are very little more advantageous to either landlord or tenant than when the farm is held at will. It is impossible to prescribe a certain course of crops without destroying every chance of improvement in the system adopted.

The course of crops on the light loams is based on the Norfolk rotation, but generally with the addition of an extra crop or two after the wheat, such as beans and oats. Although this gives more crops of corn in the six years, it is very doubtful whether on any but the richest land it is equally profitable, except where there are meadows attached to the farm on which the proper quantity of stock can be kept to produce sufficient manure. Where mangel-wurzel, tares, or other crops for cattle or sheep, are taken instead of turnips in the recurrence of the fallow crop, the four years' course will in general keep the light lands cleaner and in better heart at the least expense. In the heavier soils which have been drained, or have a porous subsoil, the convertible system, having half the land in artificial grass and half cropped, is preferable; in that case the course is—turnips or other roots,—barley or oats,—clover and grass seeds, to remain three years or more,—wheat,—beans; the beans first, if the soil is heavy, and drilled so as to admit the hoe freely. The manure is given to the turnips abundantly. A small dressing on the grass, when it is ploughed up for beans, may be advantageous to the succeeding wheat crop; but if the grass has been fed off more than once with sheep, this will not be required.

The turnips were, till within late years, almost invariably sown broadcast. The hoers were expert, and the ground appeared well covered, if the turnips escaped the fly. Many farmers could not be persuaded to try wide rows and ploughing between them; but the example of some gentlemen and opulent farmers has much shaken the faith in broadcast turnips; and wherever the row culture has been once fairly adopted, especially in the heavier loams, it has in no case been abandoned. It is not the superior weight of the turnip crop alone which renders this method preferable, but the more perfect stirring of the soil and deepening of its staple when laid in narrow and high ridges. When the turnips are given to sheep on the ground, they are cut into slices or strips by a machine, and given in troughs, which is a great improvement on the old method of folding: and if they are carted off to the cattle yard, the ridges give great facility to the carts, the wheels of which run in the furrows, as well as the horse which draws them. The introduction of the cultivation of mangel-wurzel, which is always in rows, has much diminished the prejudice against turnips in this way.

The corn crops are very generally drilled, and the hand-hoeing of wheat, just as it begins to tiller in spring, is gaining ground, and cannot fail to increase the average produce of this important grain.

On most of the stiff soils wheat is still most commonly sown on a complete fallow, and no doubt the finest crops are thus obtained. The only question is the expense. The soil is cleaner, requires less manure, and is in better condition after the wheat, than if a crop of beans or tares had preceded. But a whole year is lost every fourth year, and less food is produced for cattle; consequently less manure made. If all this be taken into consideration, the advantage of greater intervals between the fallows will soon be apparent; the best farmers find it so. Where the land has been fallowed for wheat, very good crops of barley are produced after the wheat, and this practice, however much condemned by the modern rules of agriculture, has notwithstanding many abettors. Good wheat land will produce heavier barley than light turnip land; and hence it is asserted by some that barley is better after wheat than after turnips, but no one who has had any experience of this crop will assert this to be the case on the lighter and poorer soils. The finest barley grows on good rich land after a fallow without manuring, but this is too expensive a plan, as the same land would produce a much more valuable crop of wheat.

Beans are usually dibbled across the stitches. Women put them in by a line with a short dibble. They are generally put in too close: the rows are seldom above a foot apart, and the beans about three or four inches distant in the rows. This is proved by their often dibbling nearly a sack to an acre. The land is ploughed before Christmas, and the beans are dibbled as early as the weather permits; sometimes in January, and generally before March. They are hoed by hand as soon as they have four leaves. By having the rows across the line of ploughing, the ground is more easily cut with the hoe and laid level. A second hoeing is given when the beans are a foot high, and the weeds which rise in the rows are pulled out carefully by hand. To have the work well done costs from ten to twelve shillings per acre for the two hoeings; it is often done for less, but there is little saving in having it done imperfectly. It often depends on the care taken in hoeing the beans whether a crop of wheat may be obtained after them on a single ploughing or not.

Clover and rye-grass are usually sown among the barley, either separately or mixed. The rye-grass alone is admirable food in spring for ewes and lambs. The clover is usually mown for hay, and when the two are mixed, the hay is not only more readily made, but the crop is heavier; the rye-grass shoots above the clover plant and interferes very little with its growth. Rye-grass however must not be allowed to form its seeds, for in that case it impoverishes the soil, and the wheat crop suffers in consequence.

The cultivation of sainfoin on the chalky loams is one of the great resources of the farmers on such soils. Wherever there is chalk, sainfoin will thrive, and continue to yield both hay and pasture for many years. When it wears out at last, and is ploughed up, the soil is found greatly improved for corn. By means of sainfoin many a poor chalky farm has become profitable, and yielded a double and triple rent of what it did before. Its value is fully appreciated in Oxfordshire.

The meadows in this county which lie along the banks of the rivers are productive of excellent herbage; and the hay of some of the upland meadows cannot be surpassed. This may be supposed from the fertile nature of the soil in many places. There are scarcely any irrigated water-meadows. The old pastures, which have been in that state from time immemorial, and which many would think it a sacrilege to break up, produce rich butter and good cheese with proper management. But many of the pastures are neglected: rank weeds are allowed to grow in them, and ant-hills occupy a considerable portion of the surface. A little attention would make them much more productive. In some situations, where the soil is light and friable, and where the herbage is not of the finest quality, the plough, in spite of prejudice, would greatly improve them even if laid down again in a few years. The dread of not obtaining a good sward again is removed by the improved method of laying down arable land to grass; and the experience of the value of newly-sown pastures, when fed off at first, soon reconciles the farmer to the ploughing of old grass. Many a rich meadow has no doubt been ruined by ploughing it up and taking successive crops of corn, but this is the abuse of the system. Rich grass may be let alone, but that which is inferior may be improved by a course of arable cultivation. Within a reasonable distance of Oxford, and between that city and London, the fatting of calves, by allowing them to suck the cows, is preferred to making butter. The trouble and expense are much less. There is no milking nor churning: a man and a boy can manage twenty cows easily. In summer there are more calves suckled than there are cows; and as the milk falls off the proportion is lessened, till it requires two or three cows to fatten a calf. They are of ready sale when fat; and young sucklers, three or four days old, are readily purchased from the dairies. A calf eight or nine weeks old, which costs about twenty shillings at first, will sell for 4*l.* 10*s.* to 5*l.*, giving 3*l.* 10*s.* to 4*l.* for the milk it has sucked. This is a considerable produce from one cow in full milk. Butter would not produce so much; but the value of the porkers fatted on the skimmed milk, when added to the produce of the butter, will give more than this. A careful dairyman who attends to his business makes the most that can well be got from the cows. Suckling requires less attention, and is therefore preferred by many.

The farm-horses in Oxfordshire are usually good and active; and if too many are often put together to a plough or waggon, they are the fatter and sleeker for it. If the farmer likes to spend part of his profits in having a team of fine fat horses, it is his concern; but if he prefer other comforts to the sight of a fine team, he may save a considerable portion of his expenditure, by making his horses do more work, and put out their whole strength. They must have plenty of corn inside, but not much fat on the ribs, to do a full day's work. The Oxfordshire waggons have nothing remarkable in them; they are light, and similar to the Berkshire. Single-horse carts, which are in general so much more handy and useful, are only used by a few of those proprietors and farmers who have laid aside old prejudices, and can appreciate improvements, from whatever quarter they may come. Light single-horse waggons, which have many advantages in some countries, are unknown in most parts of England: on a hard road they are even preferable to carts, both as to convenience and the load they will carry. The mode of feeding the horses in summer by soiling, chiefly with tares and cut clover, is very general, and to be commended. If the cows were kept in the stable during the heat of the day in summer, and in the cold nights of winter, more milk and butter would be produced, and the manure would well repay the trouble of giving them cut food. Some intelligent farmers have adopted this plan, and a very few feed the cows in stalls or sheds all the season.

The cows usually met with in this county are of various breeds, according to the fancy of the proprietors, some preferring the finely proportioned Devonshire cows, some the poor ill-shaped Alderneys, with their rich yellow cream. Some have cows of the old long-horned breed, but these are not now very common. The improved short-horns are now the favourite breed, both for the dairy and for calves: they fatten off readily, and always obtain fair prices. The small Ayrshire, than which a neater or more useful cow is scarcely to be found, is not very common, at least of the true breed; but those who have tried them, and reared them on the lands where they were afterwards to be fed, have had reason to be satisfied. They unite the qualities of the Alderneys and short-horns, and may probably be crossed with either, as rich milk or a good carcass is considered to be most desirable. It is a general observation in all dairies, that the cows bred at home are superior to those of the same breed brought from a distance. Most dairymen buy cows with their young calves, or ready to calve, and it is only the produce of some favourite cow which is reared now and then. These heifers having been well fed, winter and summer, from their birth, make fine cows, even if the breed be not the best. In the rich vale of the Thame the cows are chiefly of the short-horn breed, and purchased in calf at three years old. In these rich pastures they will thrive, wherever they may have been bred; but if they come from a rich country, and are transplanted on a poorer, they will not thrive so well. The short-horn breed is too large for a poor soil; the Ayrshire or North Devons are better in such situations. The latter are very good when they happen to milk well, but they often get fat at the expense of their milk. The Glamorgan cows are still in repute with some, but they are generally superseded by the short-horn and the Devon. For fatting calves, quantity of milk is of more importance than richness. In this respect the Teeswater breed is pre-eminent.

Arthur Young, in his 'View of the Agriculture of Oxfordshire,' reckons the average of butter made every week on rich pastures throughout the year at from 5lbs. to 6lbs. per cow. This will give from 260lbs. to 312lbs. per cow in the year, which is far above the highest average stated in any other county. We had occasion before to estimate the produce of a cow on very rich pasture in an adjoining county to be about 200lbs. in the year, and we are inclined to adhere to that opinion. [BUCKINGHAMSHIRE.] If we suppose his calculation to be for nine or ten months only, the two results will approach more nearly.

There are some teams of oxen for the plough, but they become fewer every year. In spite of all that has been said and written on the subject, and the many calculations of the expense of cultivation with oxen compared with horses, which are in favour of the former, every spirited farmer takes the first opportunity of getting rid of his ox-team, and using horses instead. The sluggish pace of the ox is not suited to the taste of a man who strives to introduce economy of time and active progress in his work. It is enough for him to see two active horses walking briskly with one plough, while four heavy oxen creep on with another, to become impatient of the slowness of the oxen. The oxen are fatted off without working; and if this does not give so fine-grained beef, it puts more money into the farmer's pocket, which is an irresistible argument.

Sheep are an important object with the Oxfordshire farmer, and are in general well managed. The breeds are chiefly the Leicester and South-down, and crosses between these and the Cotswold, which produces a good sheep for some situations. The pure breeds seem however to be preferred. Where fine mutton and good wool are an object, the South-downs stand foremost; where quantity of meat and wool are to be obtained in a short time, and at the least expense, the Leicesters have the preference. On short grass the South-downs thrive best; in rich meadows the Leicesters. The increased cultivation of turnips increases the number of sheep kept and fatted. On a moderately light soil with a porous subsoil, the farmer will thrive best who can maintain and feed the largest flock of sheep on his arable land. The turnips and sheep are the basis of all improved cultivation of such lands. The raising large crops of turnips on ridges, and cutting them all for the sheep and lambs, will enable a tenant to live and realise a fair profit where, without these two improvements, he would scarcely be able to pay a moderate rent.

Large hogs are prized in Oxfordshire, where enormous boars are reared and fatted to be converted into brawn. But experience proves that a moderate-sized pig, which is prolific, and at the same time fattens at an early age, is much more profitable. A cottager will have a profit on fatting his small hog to ten score, while the farmer will loose money with a huge animal which attains twenty or twenty-five score when fat. A cross with the small Chinese improves almost every native breed, by lessening the size and producing more numerous litters.

The following are the principal fairs in Oxfordshire:—

Brampton, March 26, Aug. 26; Banbury, Thursday after Jan. 18, second Thursday before Easter, Holy Thursday, Aug. 13, Oct. 30; Bicester, Friday in Easter week, Whit-Monday, Aug 5, Dec. 17; Burford, last Saturday in April, July 5; Charlbury, Jan. 1, second Friday in Lent, second Friday after May 12, Oct. 12; Chipping-Norton, March 7, May 6, July 18, Sept. 4, Oct. 3, Nov. 8; Deddingham, Aug. 21, Nov. 22; Henley, March 7, Holy Thursday; Oxford, May 3, Monday after Sept. 1; Thame, Easter Tuesday, Oct. 11; Watlington, April 5, Saturday before Oct. 10; Witney, Thursday in Easter week, Aug. 24, Thursday before Oct. 10, Thursday after Dec. 1; Woodstock, Tuesday after dlemas-day, April 5, Oct. 2, Dec. 17.

Divisions, Towns, &c.—Oxford is divided into fourteen ndreds, as follows:—

Hundreds.		Situation.	Acres.	Population.
Bampton	.	W.	42,070	14,710
Banbury	.	N.	21,230	11,449
Binfield	.	S.E.	23,040	8,607
Bloxham	.	N.	27,710	8,706
Bullington		Central & E.	46,630	12,857
Chadlington	.	N.W.	69,990	14,976
Dorchester	.	Central	11,280	3,257
Ewelme	.	S.	25,190	6,225
Langtree	.	S.	21,820	4,077
Lewknor	.	S.E.	19,780	5,096
Pirton	.	S.E.	14,190	3,319
Ploughley	.	N.E.	59,580	14,050
Thame	.	E.	10,580	4,734
Wootton	.	Central	67,590	17,907
City and Liberty of Oxford	.	Central	6,700	22,186
			467,380	152,156

Oxfordshire contains the city and university of Oxford, the borough and market towns of Banbury and Woodstock, and the market-towns of Bampton, Bicester, Burford, Chipping-Norton, Henley-upon-Thames, Thame, Watlington, and Witney. Of these, BAMPTON (population, in 1831, 1605), BANBURY (population, in 1831, 3737), BICESTER (population, in 1831, 2868), and WOODSTOCK (population, in 1831, 1380, but parliamentary limits much enlarged by Boundary Act), are described in their respective articles. The others we shall notice here.

Oxford is on the left or north-east bank of the Isis or Thames, just above the junction of the Charwell, which flows on the east side of the town. The Isis is divided at and near the town into several channels.

The origin of Oxford is unknown. The name is probably derived from there having been a ford or passage for oxen across the Thames here: it was written by the Saxons Oxnaꝼoꞃd, and in Domesday, Oxeneford. Early in the eighth century a monastery was founded here and dedicated to the Holy Trinity. Alfred is said to have coined at this town money which bore the inscription Ocsnafordia. In the Danish ravages Oxford was repeatedly injured or destroyed. Edmund Ironside died at Oxford in the year 1016, probably by assassination. Canute, his successor, frequently resided at Oxford, and held the great council of the nation here several times. Harold Harefoot, son and successor of Canute, was crowned and died at Oxford.

On the invasion of England by William the Conqueror, the townsmen of Oxford refused to admit the Normans, and in the year 1067 the town was stormed by William. In consequence of this disaster or of the other oppressive measures of the government, it suffered so much, that, according to Domesday Book, only 243 houses were able to pay the tax, while 478 houses were so 'wasted and decayed,' that they were not able to pay it; yet the unhappy townsmen were compelled to pay three times as much as in the time of Edward the Confessor. Further to bridle any attempt at revolt, a castle was built by Robert de Oilli, or Oilgi, on the site now partly occupied by the county gaol and the house of correction. The foundation of Oseney Abbey by Robert de Oilli, nephew of the builder of the castle, and the erection of a new hall or palace by Henry I., contributed to revive the prosperity of the town. In the beginning of the reign of Stephen (A.D. 1139), Oxford was the scene of a tumult, in which some persons of consequence were slain, and in consequence of which two bishops and other persons were apprehended. In the subsequent civil war, the Empress Maud was besieged in Oxford Castle by Stephen, but escaped in the night with three attendants, and the castle surrendered next morning. The ground was covered with snow, and the empress, with her attendants, clothed in white, passed unnoticed through the posts of the besiegers, and crossed the Thames, which was frozen over, on foot. The accommodation between Stephen and Henry II., by which the civil war between those princes was terminated, took place at a council held at Oxford. Several councils of state, or parliaments, were held at Oxford in the following reigns.

In the reign of Edward III. there were great dissensions arising from the theological or other disputes among the students, many of whom retired in a body to Stamford in Lincolnshire. The university and town suffered much at the same period from a pestilence, which carried off a fourth part of the students.

The doctrines propagated by Wickliffe occasioned, in the reigns of Richard II. and Henry IV. and V., much disputation and dissension at Oxford, insomuch that at one period the University was threatened with dissolution. These tumults, together with the civil war of the Roses, which occurred several years after, much depressed the place; and a dreadful pestilence soon after the accession of Henry VII. nearly depopulated the city and the colleges. The same reign was marked by the revival of the study of Greek by Erasmus, who was at Oxford in 1496. The tumults of the Reformation further tended to depress the University. In the martyrdoms of Mary's reign, those of bishops Ridley and Latimer (October, 1555), and a few months later that of archbishop Cranmer (March, 1556), took place at Oxford, in front of Baliol College.

In the reigns of Elizabeth, James I., and Charles I., the University, on which the prosperity of the town much depended, recovered in a great degree from its previous depression, and in the civil wars of Charles I., after once or twice changing masters, Oxford became the head-quarters of the king, who collected here those members of parliament who adhered to him. The members of the University supported the royal cause with great zeal; but Oxford was at last obliged to surrender, after the battle of Naseby, to the parliamentarians under Fairfax. The University was depressed under the Commonwealth, but revived on the Restoration, and in the reign of Charles II. two parliaments were held at Oxford, A.D. 1665 and 1681. In the reign of James II. the University firmly resisted the illegal proceedings of that prince, who paid Oxford a visit, and sternly rebuked and then expelled the contumacious members, whom however, from motives of fear, he afterwards restored. Subsequent to the Revolution, Oxford was regarded as the seat of Jacobite principles; and in 1715, during the rebellion in Scotland, General Pepper, with a body of dragoons, took possession of the city, confined the students to their respective colleges, and after apprehending some individuals and seizing the property of others, retired to Abingdon. A regiment of foot was afterwards quartered at Oxford to overawe the disaffected.

The city lies on a point of land nearly insulated. The city and liberty, exclusive of the borough of Woodstock and the extra-parochial district of Blenheim park, which are included in the liberty, comprehended, in 1831, an area of 1840 acres. On the east it is bounded by the Charwell or Cherwell, on the south by the main channel of the Isis, and on the west by the smaller channels of that river. It is irregularly laid out; the two principal lines of street are Bridge Street, Fish Street, the Corn Market, and St. Giles's Street, which form one line running from south to north, from the Abingdon road to the Woodstock and Birmingham road; and (Magdalen) Bridge Street and High Street, which run from the London road on the east into Fish Street and the Corn Market on the west, thus forming a ⊢ with the line just described. The other streets are for the most part parallel to these, or open into them at right angles. The town is nearly surrounded by meadows.

Oxford has much increased of late years; new streets, elegant houses, both in rows and detached, and a number of smaller tenements, have been erected. The streets are well paved and cleansed, and are lighted with gas. The police and night watch, which are regulated by the University authorities, and maintained at their expense, are very effective. The public buildings, chiefly connected with the University, are numerous, and many of them striking from their magnitude, antiquity, or beauty.

On entering the city on the east side by the London road, over Magdalen Bridge, the buildings of Magdalen College present themselves on the north side of Bridge Street, immediately adjacent to the banks of the Charwell. The college buildings are for the most part of the fifteenth century, and present some very curious features. The hall, chapel, cloisters, and entrance tower are antient; the tower is characterized by elegance and simplicity; it is crowned with eight rich pinnacles. Queen's College, in High Street, is of Grecian architecture. Nearly opposite to Queen's is University College; it presents a front of more than 260 feet to High Street, and has two gateways, each surmounted by a tower; the architecture presents some examples of Italian details mingled with more antient (or Gothic) forms. On the same side of High Street as Queen's is All Souls' College, at the corner of the opening from High Street into Radcliffe Square. It has a gateway, and some other Gothic portions of good perpendicular character, but these antient parts are mingled with others of later and incongruous architecture. Several parts of the interior, separately considered, are worthy of admiration. The opening from the High Street, just referred to, presents numerous edifices of striking character. The eastern side is occupied by All Souls' College, and the buildings of the now extinct foundation of Hertford College. On the western side is Brasen-Nose College, the buildings of which are chiefly of the earlier part of the sixteenth century, with some modern alterations or additions; the entrance-gate is a fine Gothic composition, with very good details. Between the eastern and western sides of the opening from the High Street are St. Mary's church, forming the south side of Radcliffe Square, the Radcliffe Library in the centre of the square, and the Schools forming the north side. Near the Schools the square communicates with Broad Street and Holywell Street, which form a line parallel to High Street. St. Mary's is a fine church, of good perpendicular character, except the steeple, which is of decorated character, and a porch which is of later and incongruous architecture, with twisted pillars. The church consists of a spacious nave and aisles, and a chancel without aisles. The steeple is plain, and is surmounted by a spire. The total height is 180 feet. The members of the University commonly attend divine service here. The building which contains the Radcliffe Library has a rustic basement, forming a regular polygon of sixteen sides, and of 100 feet diameter; from this basement rises a circular story divided into sixteen compartments by pairs of Corinthian columns, and surmounted by a balustrade, the compartments being occupied alternately by windows and niches. An upper circular story of much smaller diameter, surmounted by a cupola and lantern, completes the elevation. The interior is splendidly adorned, and the whole building constitutes one of the most striking edifices in the city. The 'Schools,' with the picture gallery and part of the Bodleian Library, form a quadrangle to which the rest of the Bodleian Library adjoins. The architecture of the Schools is chiefly Gothic, the exterior of a debased character, except some small portions, which are of fine composition; the interior of the Divinity School is fine, especially the roof. The Bodleian or public Library is one of the most valuable in Europe: the picture-gallery contains some interesting portraits. To the north of the Schools is an open square, the north side of which, towards Broad Street, is formed by the Clarendon (formerly the University) Printing-Office, a fine building of two stories, 115 feet long, with a Doric portico. The building was erected in 1711, from the designs of Vanbrugh. Near the Clarendon Printing-Office is 'the Theatre,' used for the more public or solemn assemblies of the University, and calculated to hold nearly 4000 persons. It is a commodious building; the part opposite the Divinity-School has a fine elevation adorned with Corinthian columns. The University press was formerly worked in the Theatre, and many of the books printed in it have a representation of the building as a vignette in the title-page.

The Museum, sometimes distinguished as the Ashmolean Museum, occupies a building adjacent to the Theatre. The collection was originally formed by the Tradescants, celebrated naturalists and herbalists of Lambeth near London, augmented by Ashmole, who presented it to the University [ASHMOLE], and further augmented by Dr. Plot and Edward Llwyd, the first keepers of the Museum, by Borlase, the historian of Cornwall, and by Reinhold Forster. The building was erected by Sir Christopher Wren. Not far from the Museum, situated back from the main streets, are Lincoln, Exeter, and Jesus Colleges. The chapel of Exeter College is a neat Gothic erection of perpendicular character. On the north side of the town, not far from the Clarendon Printing-Office, is Wadham College, the architecture of which presents an intermixture of Italian features with the elder Gothic style.

In the notice of the above-mentioned buildings we have arranged them according to their locality, proceeding from the London entrance into the centre of the town. The following are near the southern or Abingdon entrance, which is by a long bridge, or succession of bridges, over the arms of the Isis or Thames. Christ-Church College is on the eastern side of Fish Street, and consists of the great quadrangle, and another quadrangle called Peckwater, besides smaller portions. The buildings are partly of Gothic architecture and perpendicular date; but chiefly belong to a later period. The hall, built by Cardinal Wolsey, is very fine, and the entrance tower, containing the great bell, 'Tom of Oxford,' is much admired. Near the college is the cathedral of Christ-Church, which is so enclosed by college buildings and by gardens, that no good view of the whole can be well obtained. It formerly made part of the monastery of St. Frideswilde, founded about A.D. 727, for nuns, afterwards occupied by secular canons, and afterwards by regular canons of St. Austin. The monastery was suppressed by the Pope at the desire of Wolsey, in order to the establishment of the Cardinal's intended college of Christ-Church, and was subsequently (A.D. 1545), by Henry VIII., made the seat of a bishopric. The church, which is inferior to most of our cathedrals, is in the shape of a cross, with a tower and spire at the intersection of the nave and transepts. The nave and choir have each two side aisles; the north transept has an aisle on the west side; the south transept an aisle on the east side. The dimensions are given by Browne Willis as follows:—length 154 feet (155¼ feet Britton's *Cathedral Antiquities*); breadth of body and side aisles 54 feet (52 feet 10 inches, Britton); length of the transepts from north to south 102 feet; the north transept is longer than the south by one arch; the height of the roof in the western part is 41½ feet; in the eastern part or choir part, on account of the vaulting, 4 feet lower; the height of the steeple is 144 feet (146 feet, Britton). On the north side of the choir are two large chapels, the Dean's Chapel and the Latin Chapel; and on the south side of the building are the cloisters and the chapter-house, and some other apartments. The general character of the building is Norman (or, as it is sometimes called, 'Saxon'), with additions and insertions of later date. Some of our antiquaries have ascribed the erection of this church to Ethelred II. (A.D. 1002 or 1004); others, with better reason, fix the erection in the twelfth century. The chapter-house is of later date than the main building, and is a valuable specimen of the early English style, with a doorway of enriched Norman; the tower is of plain early English architecture, and the remains of the cloisters are of perpendicular date. The roof of the choir is curiously and beautifully groined, with pendants. The interior of the church has many portions deserving of attention; some of the most striking parts are of perpendicular character. The cathedral is not unfrequently overlooked by those who visit Oxford, their attention being drawn rather to the colleges than to this church. Oxford cathedral is the chapel of Christ-Church College.

In the same line of street with Christ-Church College are the churches of St. Aldate, St. Martin (or Carfax church), St. Michael, and St. Mary Magdalen, and St. John's College. The college is of mixed Gothic and Italian architecture; the church of St. Michael has an elegant though plain perpendicular porch, and some other antient portions; that of St. Mary Magdalen is mostly in the decorated style, and has some parts of remarkably beautiful composition. St. Giles's church, in the same line of street, near the northern entrance of the town, has various early English portions. The other buildings of Oxford lie back from the principal streets. New College is behind Queen's College and the late Hertford College; it has a hall, chapel, cloisters, and a bold bell-tower, of excellent perpendicular character; the chapel has been restored, and a rich screen and organ-case erected. Baliol and Trinity Colleges are near St. Mary Magdalen church; the former has some antient features. Corpus Christi, Oriel, Merton, and Pembroke Colleges are near Christ-Church College and the cathedral. Merton is rich in antient portions, and has one of the finest chapels in Oxford; it consists of the choir and transepts of a cruciform building, without any nave; there is a tower at the intersection. The choir is of decorated English character, the transepts and the tower are of perpendicular character; the tower is short and massy, surmounted by an elegant belfry story, with a pierced battlement and eight pinnacles. Worcester College is on the west side of the town. There are, besides the colleges, five halls. Of the churches, besides those already mentioned, the most worthy of notice is that of St. Peter in the east; it is originally of Norman architecture, with rich and well executed details. There is a fine Norman crypt beneath the choir. The additions are chiefly of perpendicular character.

There are some remains of Oxford castle and of the antient town wall, as well as of the works raised for the defence of the town in the civil war of Charles I. The town county hall is a spacious stone building; the county- is on the site of the castle, and there is a town-gaol or bridewell. The other chief public buildings are the Music-hall and the Radcliffe Infirmary. There are several alms-houses or school-houses, a Catholic chapel, and some Methodist or Dissenting places of worship. In the western part of the city are some remains of Rawley Abbey.

The population of the city of Oxford, in 1831, was 20,649, including the inmates of the several colleges, who amounted to 1634. The population of the adjacent parish of Binsey, which is in the liberty of the city, was 74. No particular manufacture is carried on. The prosperity of the town depends mainly on that of the University, and on its being the mart for the surrounding agricultural district. Considerable traffic is carried on, partly by land, partly by the river, or by the Oxford canal, which here communicates with it. Oxford claims to be a borough by prescription; the earliest known charter was granted by Henry II. The corporation, by the Municipal Reform Act, consists of ten aldermen and thirty councillors. Quarter-sessions for the city, petty sessions weekly, a mayor's court, and a court of hustings are held. The city magistrates have no jurisdiction over members of the University. The city is divided into five wards. Its boundary, both for municipal and parliamentary purposes, was enlarged by the Boundary and Municipal Reform Acts, the additions are not included in the statements of area and population given above. Two members are returned to parliament by the University; the right of election is in the doctors and masters of arts, the vice-chancellor being the returning officer; and two members are returned by the citizens; the number of qualified electors, in 1835-6, was 2506. The University first sent members in the reign of James I.; and the city has sent members from the commencement of our present system of popular representation.

The livings in the city are all of small value; four are in the presentation of the lord-chancellor, nine in that of one or other of the colleges. The living of Binsey, a village adjacent to Oxford, also of small value, is in the gift of Christ-Church College.

The Education Returns of 1833 give for the city three infant or dame schools, with 150 children of both sexes; fifty-three other day-schools of all kinds, containing 972 boys, 688 girls, and 252 children whose sex was not stated. There were besides two boarding-schools, and one or two schools connected with Dissenters, of which no return was obtained. Some of the day-schools were also Sunday-schools; and there were nine other Sunday-schools, with 182 boys, 261 girls, and 70 children whose sex was not stated. Binsey contains only one school, a small Sunday-school, with 10 children, supported by endowment.

Burford is in Bampton hundred, on the southern bank of the Windrush, 18 miles west by north of Oxford, through Witney. The area of the parish, including the hamlet of Upton and Signet, is 2170 acres; the population, in 1831, was 1620 for the town, above one-sixth agricultural; and 246 for the hamlet, about half agricultural: together 1866. Burford was the scene of conflict (A.D. 752) between the rival kings of Wessex and Mercia, Cuthred and Ethelbald; the latter was defeated, and his standard, a golden dragon, taken. The scene of the engagement is still distinguished as 'Battle Edge;' and Dr. Plot informs us that 'within memory' the towns-people were accustomed to have an annual procession on Midsummer-eve, in which the figures of a dragon and a giant were carried in procession, in commemoration, as he supposes, of Ethelbald's defeat. Burford was the native place of Dr. Peter Heylyn, a well-known writer of the time of Charles I.

The houses of the town are antient, and, with a few exceptions, irregular and ill-built. Some of them have antient Gothic doors of good composition, and there are some fine wooden gables with pannels and hanging tracery. Burford has diminished in wealth and importance from the decay of the coarse woollen manufacture and the malting business, which once flourished here, and from the diminished traffic along the line of road which passes through the town. The church is a large antient cruciform building; it has a central tower of Norman date, a fine Norman doorway at the west end, and various portions of Norman and early English adjacent to the tower; but the greater part of the church is of perpendicular character and of various dates. The tower is crowned with a spire of perpendicular character. There are several large chapels; a stone chapel in the nave, of good composition, is used as a seat, and there is a wooden chapel, also of good composition. The south porch is a fine specimen of late perpendicular. The roof of the nave, now much mutilated and altered, has been of remarkably fine wood-work. There are several antient monuments, a wooden pulpit, and some other portions of good wood-work, a fine circular font lined with lead, with niches and statues, and a few small portions of very good antient stained glass. Under part of the church is a crypt, used as a bone-house. There are in the town some dissenting places of worship, a school-house, an upper room in which is used as the town-hall, and several almshouses. There was anciently a small priory or hospital, dedicated to St. John the Evangelist, the revenue of which was valued at the dissolution at 13l. 6s. 6d.; its site is occupied by a mansion, still called 'The Priory,' interesting from its having been the property of the excellent Lord Falkland and of the Speaker Lenthal. Much of the old house has been taken down and rebuilt; the present mansion contains some interesting historical portraits by Holbein, Vandyke, and Cornelius Jansen.

The market is held on Saturday, and there are three yearly fairs. The town was incorporated by charter of Henry II., and is said to have sent a member to parliament for one session, and to have been relieved, on petition, of this (at that time) costly privilege. The corporation has no jurisdiction, and of late years the officers have not been regularly elected. The county magistrates hold a petty-session here. The living is a vicarage, united with the chapelry of Fulbrook, of the clear yearly value of 294l., with a glebe-house, in the gift of the bishop of Oxford.

There were, in 1833, an infant-school with 97 children; a free grammar-school, with 30 boys on the foundation and about 20 others; eight other day or boarding and day schools, with 53 boys and 87 girls; and three Sunday-schools, with 422 children. A parochial library is kept in the church vestry-room.

Chipping-Norton is in Chadlington hundred, near the head of the river Evenlode, 19½ miles north-west of Oxford by Woodstock. The town is of considerable antiquity, and is a corporate town, but has no historical interest. The area of the parish is 3440 acres, or including the hamlet of Over-Norton, 4720; the population, in 1831, was, for Chipping-Norton, 2282, about one-fifth agricultural, and for Over-Norton, 355, more than half agricultural; together, 2637. The town is situated on the slope of a considerable eminence. The streets are partially paved, but not lighted. The upper part of the town is the best built. The houses are chiefly of stone, and, though not regularly built, are many of them substantial and even ornamental. The church is a venerable Gothic building, with an embattled tower at the west end; it consists of a nave, with side aisles and a chancel. The nave is lofty, and has an oak roof richly carved and painted; it is separated from the chancel by a wooden screen. There are some remains of the antient rood-loft. To the north of the church is the elevated site of the keep of an old castle. There is a town-hall, with a lock-up-house beneath it, a free school-house, some dissenting places of worship, and some almshouses.

There is a manufactory of woollen girths and horse-cloths, which, in 1833, employed fifty persons. Some of the townsmen are engaged in the Woodstock glove trade, but the majority of the work-people reside at a distance from the town. The agricultural district is flourishing, and there is scarcely any other market-town in a circuit of 13 or 14 miles round. The market is on Wednesday, and there are several yearly fairs or great markets for cattle. The corporation has jurisdiction over the parish, except the hamlet of Over-Norton; but a more restricted boundary has been proposed. The corporate body, under the Municipal Reform Act, consists of four aldermen and twelve councillors. The borough was not to have a commission of the peace, except on petition and grant. The living is a vicarage, of the clear yearly value of 129l., with a glebe-house. There were in the whole parish, in 1833, a free grammar-school, with 16 boys; a Lancasterian school, with 40 girls; fourteen other day or boarding and day schools, with 125 boys, 119 girls, and 20 children whose sex was not distinguished; and three Sunday-schools, with 270 children.

Henley-upon-Thames is in Binfield hundred, 22 miles from Oxford. The area of the parish is 1720 acres: the population, in 1831, was 3618, not one-tenth agricultural. Henley was anciently called Hanleganc and Hanneburg. Some Roman coins have been found here, but no mention of the town occurs until after the Conquest. In 1643 it was the scene of a skirmish between the troops of Charles I. and those of the parliament. Henley is delightfully situated on a gentle ascent from the west or left bank of the Thames, amid hills covered with extensive beech woods and other plantations. The town consists of four principal streets, well paved and lighted, having a plain stone cross and conduit at their intersection: several of the houses are spacious and handsome. The entrance to the town on the east side is by a handsome stone bridge of five arches over the Thames. The church is in the eastern part of the town; it has a good tower, and several interesting portions both of decorated and perpendicular character. The east window has some good decorated tracery; and some parts of the masonry are of chequered work in flint and chalk. The town-hall in the High-street is supported by sixteen Doric columns, forming a piazza used as a market-house; the building contains a hall and council-chamber, with some rooms, and a place of temporary confinement in the basement. There are some dissenting places of worship, some almshouses, and a small theatre.

The market is on Thursday, and there are four yearly fairs. Henley is a corporate town. The boundaries of the borough are not co-extensive with those of the parish, but comprehend the greater part of the town. The officers consist of a mayor, recorder, ten aldermen, of whom the mayor is one; and sixteen burgesses, of whom the bridgemen are two. Quarter-sessions for the borough are held; the Court of Record has fallen into disuse. The borough was left untouched by the Municipal Reform Act. The living is a rectory, of the clear yearly value of 427l., with a glebe-house, in the patronage of the bishop of Rochester. There were, in 1833, an infant-school, with 165 children; a grammar-school, with 19 boys; a charity-school, with 64 boys; a national-school, with 124 boys and 72 girls; seven other day-schools, with 60 boys and 101 girls; and 'a few small schools kept by old people.' There is a savings' bank; and in the vestry of the church is the library of Dean Aldrich, rector of Henley, who died in 1737, and bequeathed his library for the free use of all the inhabitants paying church-rates. The Speaker Lenthal was a native of Henley.

Thame is in the hundred of Thame, and on the south bank of the river Thame, a feeder of the Thames, 47½ miles from the General Post-office, London, through High Wycombe and Stokenchurch. The area of the parish is 5310 acres; the population, in 1831, was 2885, about half agricultural. Thame suffered considerably in the Danish wars. In the civil war of Charles I. and the parliament, several skirmishes were fought near the town, which was surrounded by the garrisons of the contending parties. Thame consists chiefly of one long and spacious street: the market-place is tolerably commodious. The church is a large and handsome building, cruciform, and consists of a nave with side aisles, transepts, and chancel, with a fine embattled tower at the intersection of the nave and transepts, supported on four massive pillars. The architecture is early English. The entrance to the church is by a stone porch, adorned by a canopied niche, which once contained a statue of the patron saint; and the church contains several antient monuments. Near the church are the school-house, a large and noble building, with a fine school-room; and the ruins of the antient prebendal house of Thame. The school was founded by the will of Lord Williams of Thame (A.D. 1558), and among the persons educated in it were Bishop Fell, Pococke the Orientalist, Anthony à Wood, and others.

The market is held on Tuesday, and is a considerable market for corn and cattle. There are two yearly fairs, if not more. A little lace is made in the town. The river Thame is navigable from this place. The living is a vicarage, united with the vicarage of Towersey and the chapelries of Tetsworth and Sydenham, of the joint yearly value of 300l. There were in the parish, in 1833, a free-school, with 24 boys on the foundation and 30 others; a school, with 17 children, supported by subscription; and three other day or boarding schools, with 80 children; and four Sunday-schools, with 195 boys and 224 girls. The grammar-school had no pupils.

Watlington is in the hundred of Pirton, about 16 miles from Oxford. The parish has an area of 3440 acres; the population in 1831 was 1833, nearly half agricultural. The town consists of narrow streets, irregularly laid out; the houses are mean and ill built, chiefly of brick. The market-house is a substantial brick building. The church, an antient building on the north-west side of the town, contains some neat monuments. There are several Dissenting meeting-houses. A few females are engaged in lace-making, for which there is a school, attended by 30 or 40 girls: there are some corn-mills near the town. There is a small market on Saturday, and two yearly fairs. Petty sessions are held here once a fortnight. The living is a vicarage, of the clear yearly value of 175*l.* There were in the parish, in 1833, an endowed day-school, with 20 boys; two boarding-schools, with 19 boys and 20 girls; and three Sunday-schools, with 254 children.

Witney is in the hundred of Bampton, on the banks of the Windrush, chiefly on the western bank, 11 miles from Oxford. The area of that part of the parish in which the town stands is 440 acres; the population in 1831 was 3190, scarcely any part agricultural; there are beside this, the four hamlets of Crawley, Curbridge, Hailey, and Lew, with an aggregate area of 7010 acres, and a population of 2146, more than half agricultural: giving for the whole parish 7450 acres and 5336 inhabitants. Witney was a place of some consequence at an early period. It sent members to parliament in the time of Edward II., but discontinued doing so in the following reign. The manufacture of blankets was early established here, and Dr. Plot says that in his time 3000 persons were engaged in the weaving business, from children of eight years to decrepit old people. In the latter part of the last century, the manufacture declined greatly. The introduction of machinery has again extended it; and in 1831 it employed about 200 adult males in the town and 70 in the adjacent hamlets, besides females and children. The town is in a pleasant situation, and consists of two principal streets. The houses are generally of respectable appearance, and many of them spacious and handsome. Few towns containing so many inhabitants, especially with a large proportion of them engaged in manufacture, retain so quiet and rural an appearance. There are in the High Street a 'staple or blanket hall,' a handsome building, erected A.D. 1721; a town-hall, built of stone, with a piazza underneath for a market-house; and a market-cross, built A.D. 1683, and repaired A.D. 1811. The house for the free-school, comprehending a spacious school-room, a room annexed for the library, and the master's apartments, is a respectable building. 'The church is a large and handsome cross church, with a tower and a lofty spire at the intersection; the nave has aisles and a clerestory; the transepts are large, and the chancel small. The tower and chancel are early English, and the north transept decorated with a fine window of seven lights; the clerestory and some other parts are perpendicular.' (Rickman.) There are several dissenting meeting-houses. The manufacture of rough coatings, of tilts for barges, of felt for paper-makers, and of gloves, is carried on to a small extent; wool-stapling is extensively carried on, and there is a considerable malt-trade. The Witney blankets are of superior texture and good colour. The market is on Thursday, and there are several yearly fairs.

The living is a rectory, of the clear yearly value of 1290*l.*, in the gift of the bishop of Winchester. There were in the town of Witney, in 1833, one dame-school, with 15 children; the free grammar-school, with 16 boys; an endowed charity school, with 15 boys and 25 girls; two national schools, with 110 boys and 70 girls; five other day or boarding schools, with 47 boys and 97 girls; and two Sunday-schools, with 306 boys and 329 girls. The national schools were attended by 70 boys and 50 girls on Sundays.

Beside the above market-towns, the county contains several large villages. Ensham, or Eynsham, is on a hill on the northern bank of the Thames, in Wootton hundred, about five miles from Oxford on the road to Witney. The area of the parish is 5060 acres; the population in 1831 was 1859, two-thirds agricultural. The village is in a picturesque situation; it has two bridges, one of which is over the Thames. The parish church is a large Gothic building, with a substantially built western tower; and near the church is an antient cross, with a taper shaft of elegant proportions. Ensham had formerly a Benedictine Abbey, the yearly revenue of which, at the dissolution, was 441*l.* 12*s.* 2¾*d.* gross, or 421*l.* 16*s.* 1¾*d.* clear. There are some [illegible] remains of the building. The living is a vicarage, of yearly value of 178*l.*, with a glebe-house. There 833 an endowed school, with 14 boys and 4 girls; three other day or boarding schools, with 40 boys and 63 girls; and two Sunday-schools, with 90 children.

Deddington is in Wootton hundred, 17 miles from Oxford. The area of the parish is 2350 acres, or, including the hamlets of Clifton and Hempton, 3990 acres; the population in 1831 was 1590, or with the hamlets 2078. There was antiently a castle here, but only the earth-works and perhaps some traces of the foundations remain. It was at Deddington that the Earl of Warwick seized Piers Gaveston. It was at this time a market and corporate town, and sent members to parliament. It was relieved from the burden of sending members, on petition, in the following reign. The corporation has fallen into disuse, and the market has of late years been discontinued. There is a cattle-fair yearly. The houses of the village are, with few exceptions, small, and are built of an ordinary stone quarried in the neighbourhood. The church is antient, and contains some portions worthy of examination. The living is a vicarage, of the clear yearly value of 133*l.*, with a glebe-house. In the whole parish there were, in 1833, ten dame-schools, with about 110 children; a national school, with 100 boys and 90 girls (124 boys and 100 girls on Sunday); and a Sunday-school with 26 boys and 50 girls. Chief Justice Scroggs was a native of Deddington.

Hook-Norton is in Chadlington hundred, near Chipping-Norton. The area of the parish is 3730 acres; the population in 1831 was 1506, two-thirds agricultural. There was a battle fought here between the Saxons and Danes in the time of Edward the Elder; a barrow in the parish is thought to be a memorial of this engagement. The living is a perpetual curacy, of the clear yearly value of 180*l.* There were in the parish, in 1833, three dame-schools, with 22 boys and 23 girls; a national school, with 30 girls; four other day or boarding schools, with 55 boys and 37 girls; and two Sunday-schools, with above 200 children.

Charlbury is in a detached portion of Banbury hundred, between Chipping-Norton and Witney. The area of the parish is 4810 acres, or, including the dependent hamlets of Fawler, Finstock, and Walcott, and the chapelries of Chilson and Pudlicot, and of East Chadlington (with the tithing of West Chadlington), 11,320 acres; with a population, in 1831, of 1433, or including the dependencies, of 3027. There are four yearly fairs. The living is a vicarage united with the chapelries of Chadlington and Shorthampton, of the joint yearly value of 800*l.*, with a glebe-house, in the gift of St. John's College, Oxford. There were in 1833, in the whole parish, four dame-schools, with 28 children; a Lancasterian school, partly supported by endowment, with 94 boys and 76 girls; a school supported by subscription, with 10 boys and 10 girls; eight other day-schools, with 63 boys, 45 girls, and 109 children of sex not distinguished; and seven Sunday-schools, with 328 children. There is a valuable endowment for a grammar-school, but the school is not kept up. There is a lending library at Charlbury.

Headington is in Bullington hundred, about 1½ mile north-east of Oxford. The parish has an area of [illegible] acres, with a population, in 1831, of 1388, about one-fourth agricultural. Headington is supposed to have been a royal residence under the Saxon dynasty. The village is pleasantly situated on a hill, which commands a fine view of Oxford; and contains some neat and commodious buildings. The church is antient, but the tower was rebuilt A.D. 1689; there is a lofty shaft of a cross in the church-yard. A short distance from the village is a stone-quarry from which much of the stone has been taken for the various buildings at Oxford; it is however only suited to the more substantial parts, being too porous and too coarse in the grain for ornamental work. The living is a rectory, of the clear yearly value of 118*l.* The were in 1833, an endowed school, with 20 boys and 10 girls; five other day-schools, with 36 boys and 36 girls; and two Sunday-schools, with 39 boys and 31 girls.

Caversham is in Binfield hundred, on the north bank of the Thames, about one mile from Reading in Berkshire. Here was formerly a cell of regular canons of St. Austin, belonging to Noctele or Nutley Abbey in Buckinghamshire, to which abbey the church also belonged. This church is small, and some parts are of great antiquity. Caversham was the scene of a smart skirmish during the siege of Reading by the Parliamentarians in the civil war of Charles I. The area of the parish is 5100 acres; the population in 1831 was 1362, about half agricultural. The living is a perpetual curacy, of the clear yearly value of 116l., with a glebe-house. There were in 1833, a national school, with 98 boys and 53 girls; and three other day or boarding schools, with 51 girls and 15 boys; and two Sunday-schools, with 103 children.

Bloxham, in Bloxham hundred, near Banbury, has an area of 2980 acres, or, including the chapelry of Milcombe, 4740 acres: the population of Bloxham in 1831 was 1348, of Milcombe 225; together 1573. The village of Bloxham is of considerable extent. The church is a handsome building, with a lofty and elegant tower and spire; the west door has some curious carving in stone, representing the Day of Judgment. The living is a vicarage united with the chapelry of Milcombe, of the clear yearly value of 660l., with a glebe-house. There were in the whole parish, in 1833, three dame-schools, with 46 children; an endowed free-school with 35 boys; four other boarding or day schools, with 18 boys, 76 girls, and 20 children of sex not distinguished; and six Sunday-schools, with 92 boys, 75 girls, and 90 children of sex not distinguished.

Stokenchurch is in Lewknor hundred, on the road from London by High Wycombe to Oxford, 18 miles from Oxford. The area of the parish is 4060 acres; the population in 1831 was 1276, above one-third agricultural. The church is ancient and presents some peculiar features. Several Roman urns were dug up about a century ago. About 70 men in this parish and the adjacent parish of Chinnor (area 1790 acres, or, with the liberty of Henton, 2760 acres; population in all 1255) are employed in chair-making. The living of Stokenchurch is a chapelry united with the vicarage of Aston Rowant, of the joint yearly value of 176l., with a glebe-house. There were in 1833, one dame-school, with 20 children; two boarding or day schools, with 45 children; six lace-making schools, with 90 children; and three Sunday-schools, with 231 children.

Bensington, in speaking usually shortened into Benson, is in the hundred of Ewelme, on the road from London, by Henley-on-Thames, to Oxford. It is on the left or east bank of the Thames, a little above Wallingford. Bensington was a place of importance in early times. It was taken from the Britons by the West Saxons under Cuthwin, brother of Ceawlin, king of Wessex, A.D. 572. The West Saxons built a castle here for the defence of their frontier; this castle was reduced by the Mercians under Offa, who defeated Cynewulf of Wessex here, A.D. 775. The village has some good houses; the church is ancient, it has an east window of decorated character; the tower is modern. The living is a perpetual curacy, of the clear yearly value of 119l., with a glebe-house. There were in 1833, two day-schools, with 70 children; two day and Sunday schools, with 100 children; and one Sunday school, with 30 children.

Dorchester, at the junction of the Thame and the Isis or Thames, is in the hundred of Dorchester; the area of the parish is 900 acres; the population in 1831 was 888, chiefly agricultural. The termination 'chester' indicates that it was a Roman station; and it appears to have been the Durocina of Richard of Cirencester. The foundations of an ancient town wall (whether Roman or not our authorities do not state) are frequently dug up; an extensive embankment called Dykehills, near the village, has given scope for much conjecture; and Dorchester and its immediate neighbourhood have yielded an abundant harvest of coins and other relics of antiquity. The town appears to have been at the height of its prosperity in the seventh century, when it was made the seat of a bishopric, which comprehended the two kingdoms of Mercia and Wessex. The bishopric was subsequently diminished by the formation of new sees, but was still the largest in England, when the seat of it was removed to Lincoln, A.D. 1086. The place had however previously declined, owing to the ravages of the Danes. There was a castle built here, in the middle ages, of which little yet remains. In the year 1140 an abbey of Black Canons was founded here, which had at the dissolution a yearly revenue of 219l. 12s. 0d. Some parts of the building yet remain near the church. The church of Dorchester is a large and curious church, with portions of different dates mixed together. The building is imperfect and the plan of it very irregular. There are portions in all the varying styles of Gothic architecture, and other portions in which there is a transition from one style to another. The door at the western end of the north aisle is Norman, but the greater part of the church is of later date. There are some good antient monuments, and a very antient font. The fragment of the antient abbey has been converted into a cottage. There is a modern bridge over the Thames at Dorchester, built of Headington stone. The living of Dorchester is a perpetual curacy, in the jurisdiction of the peculiar court of Dorchester, of the clear yearly value of 100l. There were in the parish, in 1833, an endowed school, with 40 boys and 10 girls; two other day-schools, with 10 boys and 23 girls; and one Sunday-school, with 18 boys and 30 girls.

Divisions for Ecclesiastical and Legal Purposes.—This county is in the diocese of Oxford, of which, till lately, it constituted the whole. By virtue of an order in council, the archdeaconry of Berks has been transferred from the see of Salisbury, pursuant to the recommendation of the Ecclesiastical Commissioners; and it is further proposed to add the archdeaconry of Bucks, now in the diocese of Lincoln. All these are in the ecclesiastical province of Canterbury.

The diocese of Oxford is of late origin. After the dissolution of the monasteries, Henry VIII. proposed to establish eleven new bishoprics, of which he actually established six, the embarrassments consequent on his extravagance having interfered with the execution of the remainder of his project. Of the six bishoprics thus established, Oxford was one. The seat of it was at first fixed (A.D. 1542) in the magnificent abbey church of Osney, from which it was shortly afterward (A.D. 1546) removed to the far inferior structure in which it is now fixed. The diocese consisted of the county of Oxford, and formed one archdeaconry, that of Oxford, with the exception of ten parishes which are in the peculiar jurisdiction of Dorchester (formerly under Dorchester abbey), and a few other parishes, which are peculiars, or otherwise exempt. The archdeaconry is subdivided into the rural deaneries of Aston, Burcester or Bicester, Chipping-Norton, Cuddesden, Deddington, Henley, Witney, and Woodstock, and the deanery of the city of Oxford. The number of parishes in the diocese, including those of exempt jurisdiction, was given by Browne Willis (A.D. 1742) at one hundred and ninety-five; the number of churches and chapels was given by the same authority at two hundred and fifty, some of them however in ruins. The number of livings, in 1831, according to the Parliamentary Returns, was two hundred and six; the number of churches at the same period was one hundred and ninety-seven, of chapels thirty-one. The revenue of the bishopric, on the average of three years ending 1831, was returned at 3106l. gross, or 2648l. net; but it was expected materially to decrease. The revenue of the cathedral church is so united with that of Christ-Church College that it cannot be separately stated; the gross revenue at the above-mentioned period was 26,893l., the net revenue 12,203l., beside houses for the dean and canons. The establishment of the cathedral comprehends the bishop, dean, archdeacon, and eight canons, beside chaplains, clerks, choristers, and almsmen. The dean and canons have no separate revenues. The archdeaconry of Berkshire, now added to the diocese, comprehends the four rural deaneries of Abingdon, Newbury, Reading, and Wallingford.

The county is in the Oxford circuit. The assizes and quarter-sessions are held at Oxford, where the county gaol and house of correction stands. This prison can contain 137 prisoners, with separate sleeping-cells, or 308 when more prisoners than one sleep in a cell. The number of offenders committed for trial or bailed in the county, in 1837, was 272, of whom 89 were not prosecuted, or had no true bill found against them, or were acquitted on their trial; and 183 were convicted, 4 for capital offences. More than half the offenders were charged with simple larceny. Of the offenders, 101 were entirely ignorant, 139 could read and write imperfectly, and 22 could read and write well; the degree of instruction received by the rest could not be ascertained. There were 6 offenders under twelve years of age, and 27 more under sixteen. There is no county lunatic asylum.

Before the Reform Act, Oxfordshire returned nine members to parliament, viz. two for the county, who were elected at Oxford; two for Oxford city, and two for the University; two for the borough of Woodstock, and one for the borough of Banbury. By the Reform Act three members were to be returned by the county, the place of election continuing as before at Oxford; and the polling-stations being Oxford, Deddington, Witney, and Nettlebed, between Henley and Oxford. Woodstock was reduced to one member; so that the total number remained as before.

History and Antiquities.—The county was probably divided between the two Celtic nations, the Catyeuchlani and the Dobuni; of whom the former held the eastern and the latter the western parts. The Dobuni were in subjection to the Catyeuchlani, and upon the approach of the Romans, under the propraetor Aulus Plautius, readily submitted to him. In the Roman division of the island, Oxfordshire was included in the province of Flavia Cæsariensis.

The most remarkable monument of this early period, if indeed it may be referred to it, is the singular group of Rollrich or Rowldrich stones, about three miles north-west from Chipping-Norton. These stones are near the north-western slope of the long range of hills which skirt the county on that side, along the border of Gloucestershire and Warwickshire. They form a ring, not exactly circular, of about one hundred feet diameter, and appear to have been originally sixty in number; there are now however only twenty-four that are more than one foot above the level of the soil, nor do any rise more than five feet above the ground, except one, precisely at the northern point, which exceeds seven feet; the thickness of this stone is considerable, but not uniform; the thickness of the others rarely exceeds thirteen or fourteen inches. The whole appear to have been taken from a neighbouring quarry and placed in their present situation in a rude and unformed state. The entrance to the circle appears to have been on the north-east; but there are no marks of any surrounding trench, or any avenue of approach; neither have any indications of burial been discovered. About two hundred and fifty feet north-east of the circle, opposite the entrance, is a single stone, popularly termed 'the king-stone,' nine feet in height; and on the east are the remains of another group, called 'the Five Knights.' The conjectures of antiquaries as to the origin of this monument are very contradictory, and some of them sufficiently absurd.

Several antient British or Roman roads crossed this county. Icknield Street or Way crossed the narrow part of it just under the Chiltern Hills, passing near the town of Watlington to the banks of the Thames at Goring, between Wallingford and Reading. Akeman Street crossed it in the wider part, passing through the Roman station at Alchester, near Bicester; and then passing near Woodstock, Witney, and Burford. Another road ran northward from Dorchester on the Thames to Alchester, and from thence into Northamptonshire; and one road from Londinium (London) ran north-westward to Alchester, while another, crossing the Thames north of Henley, ran to Wallingford. None of the towns or stations mentioned by Ptolemy, or in the 'Antonine Itinerary,' were in this county. At Alchester are the remains of a square camp or station, with a ditch and bank, the sides facing the four cardinal points. It is said (Reynolds, *Iter Britanniarum*) that many parts of the streets can be traced. Some have proposed to fix here the station Isanavatia, which others identify with Burnt Walls, near Daventry [NORTHAMPTONSHIRE]; but it seems more likely to have been the Aelia Castra of Richard of Cirencester. Numerous coins and other antiquities have been discovered here; Roman bricks are frequently found in the fields, and foundations are turned up by the plough. The neighbouring town of Bicester and the village of Great Chesterton bear in their names traces of Roman occupation. Dorchester on the Thames was probably the Dorocina of Richard. No other Roman town or station has been identified, but urns, coins, and other antiquities have been found at various places. There are traces of a Roman camp near Chadlington, in the neighbourhood of Chipping-Norton, and of another near Kiddington, between Chipping-Norton and Woodstock; the latter is in excellent preservation, though little noticed. Remains of tessellated pavements have been dug up at Steeple Aston, between Deddington and Woodstock, at Great Tew and Wigginton, between Deddington and Chipping-Norton, and at Stonesfield, near Woodstock; the latter was thirty-five feet by twenty, and the tessellæ were of seven different colours. Many years after this discovery, the areas of several large partments with tessellated pavements were found on the me spot, together with a brick hypocaust with funnels and a bath with lead pipes in the sides covered with plaster painted red. The Roman bricks appeared fresh and sound. At Wilcot, south of Charlbury, are the vestiges of a Roman work for making bricks, tiles, and stucco; also a tumulus with fragments of Roman bricks and cement. Wilcot, Stonesfield, and Alchester are all near the line of Akeman Street.

In the conquest of the island by the Saxons, Oxfordshire was the scene of conflict on different occasions. The West Saxons, under Cynric, their second king, and his son Ceaulin, or Ceawlin, or Cealwin, defeated the Britons at Beranbyrig, perhaps Banbury (A.D. 556). In the following reign of Ceawlin, or Cealwin (A.D. 571 or 572), Bensington and Eynsham were taken from the Britons; but the acquisitions of the West Saxons north of the Thames appear never to have been permanent. Cynegils, and his brother or son Cwichelm, joint kings of Wessex, defeated the Britons at Beamdune, or Bampton (A.D. 614); and the circumstance of the Britons being parties to this conflict, renders it probable that the county had not yet been wrested from them. The extension of the Mercian power under Penda probably led to its subjugation. The see of Dorchester (established about 635 or 638) is said to have comprehended the two kingdoms of Wessex and Mercia: it is therefore probable that Mercia by this time comprehended Oxfordshire, in which case the see was appropriately fixed on the frontier of the two kingdoms. In the year 752 a battle was fought at Burford between Cuthred of Wessex and Ethelbald of Mercia, in which the former, who had revolted against the supremacy of Ethelbald, was victorious, and regained his independence. Probably also he succeeded in uniting some parts of Oxfordshire to Wessex; for in 775 Offa took Bensington from the West Saxons, after gaining a victory over the king Cynewulf. When the Anglo-Saxon kingdoms were destroyed, either by the growing power of Wessex or the invasion of the Danes, Oxfordshire was included in that part of Mercia which was under the West Saxon crown; but on the death of Ethelred, ealdorman of Mercia, Edward the Elder, the West Saxon king, took Oxford under his immediate government, leaving the rest of the county to Ethelfleda, his sister, the widow of Ethelred. The county suffered much in the struggle which Ethelred I. and Edward the Elder had to maintain against the Danes: it suffered again when the struggle was renewed, in the reigns of Ethelred II. and Edmund Ironside. Upon the division of the kingdom between the latter and Canute (A.D. 1016), Oxfordshire appears to have fallen to Canute; and about this time (A.D. 1015 and 1018) two great councils or assemblies of Danes and English were held at Oxford. In the time of the Confessor, Oxfordshire was included in the earldom of Gurth, the brother of Harold. (Palgrave's *Rise and Progress of the English Commonwealth*, *Proofs and Illustrations*)

Of this troubled period there are several memorials in the encampments, which may be traced in different parts of the county. There are camps or other earthworks on Britwell Hill, near Watlington; at Dyke Hills, near Dorchester; near Bensington; near Wootton, in the neighbourhood of Woodstock; at Knollbury Banks, between Chadlington and Saresden, in the neighbourhood of Chipping-Norton; at Madmarston, or Mad Mason, and in another place near Tadmarton, between Banbury and Chipping Norton. The authors and date of these works cannot now be ascertained. The works at Dyke Hills consist of a double entrenchment, three-quarters of a mile long, the banks are sixty feet asunder at bottom, and their perpendicular height is twenty feet: the entrenchment constitutes the chord of an arc formed by the junction of the Thame and the Isis or Thames, to which it is adjacent. The vallum of the camp at Knollbury Banks is very steep, and is composed of rubble-stone cemented, and coated with turf. At Mongewell, on the Thames, below Wallingford, is a remarkable vallum or high ridgeway, extending south by east nearly two miles and a half in the direction of Nuffield, near which the bank becomes double, with a deep trench between. It is called Grimes Dyke, or popularly, Grime's Ditch, or Devil's Ditch. Dr. Plot was told that it held on its course to the Thames below Henley, where it crossed the river into Berkshire; but it cannot now be traced beyond Nuffield in that direction. There are several barrows in the county, chiefly on the north-western side.

The subsequent events which occurred in the county until the War of the Roses were chiefly connected with the town or castle of Oxford, and have been noticed above. In the reign of Richard II., Robert de Vere, earl of Oxford, was defeated at Radcot Bridge, near Bampton, by the insurgent nobles (A.D. 1387). In the War of the Roses, a great battle was fought near Banbury (A.D. 1469), between the northern insurgents, under their captain, Robin of Redesdale, and the Yorkist or royalist army, under Herbert, earl of Pembroke. The earl had quarrelled with his coadjutor, Lord Stafford, by whom he was abandoned. He was defeated and taken, and next day beheaded by the rebels. No other event of interest occurred in the county before the Reformation.

Of the Anglo-Norman period there are several monuments in the ruins of castles and religious edifices, but none of them of great extent. Of Oxford and Banbury castles there are scarcely any traces; Dorchester Castle has entirely disappeared. Of Bampton Castle there are some remains, now converted into a farm-house: this castle was probably of the date of Edward II. or III., but the interior has some ornaments of later date, especially a representation of the Red and White Roses united. Broughton Castle, near Banbury, is surrounded by a broad and deep moat, crossed by a bridge of two arches. An antient tower forms the entrance to the court, and several other parts of the antient edifice are standing, to which some additions of a later date have been made. There are castellated or other antient mansions at Castleton, near Chipping-Norton; the High Lodge, near Woodstock; at Astall, or Asthall, near Witney; in Holton Park (the old mansion), between Stokenchurch and Oxford; and at Stanton Harcourt, near Bampton, where is a kitchen resembling the abbot's kitchen at Glastonbury.

There are some fragments of Minster Lovel House, near Witney. The chief part of the mansion was pulled down nearly a century ago: but the current story of the body of Lord Lovel (one of the supporters of Perkin Warbeck, supposed to have been killed in the battle of Stoke by Newark, A.D. 1487) [NOTTINGHAMSHIRE] having been found in a vault, is without solid foundation.

The chief ecclesiastical buildings are the churches of Oxford (the cathedral especially), Burford, Henley, Dorchester, and Witney, mentioned above. Iffley Church is principally Norman, with an addition to the chancel of early English character, and some inserted windows of decorated and perpendicular date. The Norman portion is remarkably well executed: it has a groined chancel, three fine doorways, and a handsome west end. The churches of Hanborough, Swinbrook, and Great Tew, and Whiteford Chapel near Burford, have early Norman portions. The more antient buildings of the colleges at Oxford have been noticed. Of monastic remains there are but few, and those not striking. Of Osney Abbey, once so magnificent, and of Godstow Nunnery, near Oxford, the ruins are small; those of Godstow consist of ranges of wall on the north, south, and east sides of an extensive area, and a small building at one angle. Godstow has some historical interest, from its being the scene of the early life of Rosamond, daughter of Lord Clifford, the 'fair Rosamond' of Henry II., and the place of her interment. The story of her being poisoned by the jealous Eleanor, Henry's queen, is a popular fiction. Henry placed Rosamond during the continuance of their amour in a house, or, as it was anciently termed, 'a bower,' which he had at Woodstock. It seems however that their intercourse was broken off on Henry's marriage, and Rosamond retired to Godstow, where she lived in penitence and seclusion till her death. She was buried at first before the high altar; but her remains were afterwards removed out of the church into the chapter-house, which is probably the building at the angle of the enclosure yet remaining. At the Reformation her bones were taken up and the tomb destroyed. Leland, who mentions this fact, says that her bones were closed in leather, and outside that with lead; and that when these were opened, 'a sweet smell came out.' Of an antient hospital at Banbury there are some remains, now converted into a barn; part of the priory of Cogges, near Witney, is now converted into a farm-house; of Bruern Abbey and Goring Nunnery there are some slight remains; and the fragments of Thame Abbey, which are considerable, are connected with the modern mansion erected on their site. Part of the shell of a small alien priory at Minster Lovel is yet standing.

In the civil war of Charles I. this county was the scene of several severe actions. Oxford was seized by Sir John Byron, a royalist, at the beginning of the contest: he however was driven from it by Lord Say, then lieutenant of the county; but the king recovered it after the battle of Edge-hill, A.D. 1642. He also took Banbury and Broughton castles, the former with a strong garrison. At Oxford, Charles assembled those members of the two houses who adhered to him, and formed them into a parliament of his own, which met in the great hall of Christ Church College. Here the commissioners of the parliament waited on the king (A.D. 1643) with proposals of peace, but these negotiations were soon broken off. In the same year a severe skirmish took place at Caversham Bridge between a body of the parliamentary army, then besieging Reading, and a body of the king's troops, under Prince Rupert and General Ruthven, who attempted to relieve the town; and about two months after occurred the skirmish of Chalgrove Field, near Watlington. Prince Rupert had beaten up the quarters of the parliamentary army near Thame, and was returning to Oxford with many prisoners, when he was overtaken by the parliamentarians, whom he repulsed. It was in this skirmish that Hampden was mortally wounded: he died at Thame three weeks after. In the summer of 1644, Waller and the parliamentary armies of Essex besieged Oxford, but retired from the city on learning that the king had left it. An indecisive skirmish was fought soon after at Cropredy, near Banbury, between the king's army and that of Waller. Banbury Castle was subsequently besieged by a body of parliamentarians under Colonel Fiennes, but the siege was raised on the approach of a royalist detachment under the earl of Northampton. In April, 1645, Cromwell beat a body of royalist cavalry at Islip Bridge, between Oxford and Bicester, and obliged Colonel Windebank, who occupied Bletchingdon House with a garrison of two hundred men, to surrender. Oxford was soon after besieged by Fairfax; but the siege was raised, in consequence of the king's attack upon Leicester; and the king, after his defeat at Naseby, found shelter in this city all the winter. In 1646 the parliamentarians took Woodstock manor-house and Banbury Castle by capitulation; and the garrison of Oxford, which was again besieged by Fairfax, surrendered by order of the king, who had given himself up into the hands of his enemies. No political event of interest has occurred since, except the occupation of the city of Oxford by a regiment of dragoons in the rebellion of 1715.

STATISTICS.

Population.—Oxfordshire is chiefly an agricultural county, it being the eleventh in the list of agricultural counties. Of 39,023 male inhabitants twenty years of age and upwards, 19,500 are engaged in agricultural pursuits, while only 711 are employed in manufactures or in making manufacturing machinery. Of these latter, 290 men were employed, in 1831, at Witney, in making blankets; 60 at Hailey, and 11 at Crawley. In Banbury and its vicinity, 125 men were employed in plush and girth making, and 40 at West Shefford, Bourton, and Wardington. There were some few weavers at Bloxham, Adderbury, and elsewhere. Glove-making gives employment to some of the population in the vicinity of Woodstock. Many females are occupied in this work; and about 57 men are noticed as being thus employed. Horse-clothing is made at Chipping-Norton, and a small number of men are employed in some few other manufactures.

The population of Oxfordshire, at each of the four following periods, was:—

	Males.	Females.	Total.	Increase per cent.
1801	53,786	55,834	109,620	..
1811	59,132	60,059	119,191	8·73
1821	68,817	68,154	136,971	14·91
1831	75,957	75,769	151,726	10·77

shewing an increase between the first and last periods of 42,106, or about 38½ per cent. on the whole population, being 19½ per cent. below the whole rate of increase throughout England.

The following table exhibits a summary of the population, &c., of every hundred, as taken in 1831.

HUNDREDS, CITY, AND LIBERTY.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.

Totals .	29,334	31,770	197	849	15,304	9,454	7,012	76,387	75,769	152,156	39,023

County Expenses, Crime, &c.—The sums expended for the relief of the poor, at the four dates of—

		£.		s.	d.	
1801	were	88,689,	being	16	2	for each inhabitant.
1811	. .	143,108	„	24	0	„
1821	. .	115,646	„	16	10	„
1831	. .	130,043	„	17	1	„

The sum expended for the same purpose for the year ending March, 1838, was 64,314*l.*; and assuming that the population had increased from 1831 to 1838 in the same rate of progression as in the ten years preceding 1831, the above sum gives an average of about *7s.* 11*d.* for each inhabitant. These averages are above those for the whole of England and Wales.

The sum raised in this county for poor-rate, county-rate, and other local purposes, in the year ending 25th March, 1833, was 158,630*l.*, and was levied upon the various descriptions of property as follows:—

On land . .	£128,375	9*s.*
Dwelling-houses .	26,964	0
Mills, factories, &c. .	1,462	5
Manorial profits, navigation, &c.	1,848	9
Total	£158,630	3

The amount expended was—

For the relief of the poor . .	£130,607	7*s.*
In suits of law, removal of paupers, &c.	4,278	10
For other purposes . .	23,698	19
Total money expended	£158,584	16

In the Returns made up for subsequent years, the descriptions of property assessed are not specified. In the years 1834, 1835, 1836, 1837, and 1838, there were raised 150,335*l.* 6*s.*, 129,482*l.* 5*s.*, 95,547*l.* 10*s.*, (not stated for 1837), and 78,742*l.* respectively; and the expenditure of each year was as follows:—

	1834.	1835.	1836.	1837.	1838.
	£	£	£	£	£
For the relief of the poor	129,615	106,640	77,322	66,483	64,314
In suits of law, removal of paupers &c. .	4,441	2,150	1,823	1,134	1,102
Payments towards the county rate . .	15,392	8,491	9,145	not given	7,996
For all other purposes		11,695	7,167	4,795	7,026
Total money expended	£149,448	128,976	95,457		80,438

The saving effected in the sum expended in 1838, as compared with that expended in 1834, was therefore 69,010*l.* 11*s.*, or about 46 per cent.; and the sum expended for the relief of the poor in 1838 was less than that in 1834 by 56,301*l.*, or about 46½ per cent.

The number of turnpike trusts in Oxfordshire, as ascertained in 1836, under the Acts 3 and 4 Wm. IV., c. 80, was 21; the number of miles of road under their charge was 342. The annual income arising from tolls and parish compositions in lieu of statute duty in 1836 was 24,784*l.* 4*s.* and the annual expenditure in the same year was as follows:—

	£.	s.	d.
Manual labour . . .	9,975	7	0
Team labour and carriage of materials	638	2	0
Materials for surface repairs .	2,114	1	0
Land purchased . . .	38	0	0
Damages done in obtaining materials	308	12	0
Tradesmen's bills . .	1,006	17	0
Salaries of treasurer, clerk, and surveyor	1,123	0	0
Law charges . . .	1,293	3	0
Interest of debt . . .	5,230	16	0
Improvements . . .	1,576	5	0
Debts paid off . . .	773	8	0
Incidental expenses . .	596	8	0
Estimated value of statute duty performed . . .	151	16	0
Total expenditure	£24,835	15	0

The county expenditure in 1834, exclusive of that for the relief of the poor, was 8775*l.*, disbursed as follows:—

	£.	s.	d.
Bridges, building, repairs, &c.	933	15	0
Gaols, houses of correction, &c., and maintaining prisoners, &c. .	3,091	5	0
Shire-halls and courts of justice, building, repairing, &c. . .	29	15	0
Prosecutions . . .	1,804	19	0
Clerk of the peace . .	691	1	0
Conveyance of prisoners before trial	491	1	0
Conveyance of transports .	128	2	0
Vagrants, apprehending and conveying	191	2	0
Constables, high and special .	1,006	13	0
Coroner . . .	177	12	0
Miscellaneous . . .	229	15	0
Total expenditure	£8,775	0	0

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 746, 942, and 1425 respectively, making an average of 106 annually in the first period, of 134 in the second period, and of 203 in the third period. The number of persons tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 87, 60, and 65 respectively. Among the persons charged with offences there were committed for—

	1831.	1832.	1833.
Felonies . .	65	50	59
Misdemeanors .	22	10	6

The total number of committals in each of the same years was 168, 101, and 124 respectively.

	[illegible]	[illegible]	[illegible]
The number convicted was	117	87	71
The number acquitted was	36	14	29
Discharged by proclamation	15	[illegible]	24

There were 277 persons charged with crimes at the assizes and sessions in Oxfordshire in 1836. Of these 25 were charged with offences against the person, 15 of which were common assaults; 10 were charged with offences against property committed with violence; 222 with offences against property committed without violence; 3 for malicious offences against property; 3 for forging and uttering counterfeit coin; and 14 for various misdemeanors.

Of the whole number committed, 192 were convicted, 56 were acquitted, 4 were not prosecuted, and no bill was found against 25. Of those convicted, 2 were sentenced to transportation for life, and 47 for various other periods; 2 were sentenced to imprisonment for two years or above one year; 24 for one year or above six months; and 117 for six months or under; [illegible] were fined. Of the whole number of offenders, 243 were males and 34 females; 98 could neither read nor write; 148 could read and write imperfectly; 22 could read and write well; the degree of instruction of the remaining 19 could not be ascertained.

The number of persons registered in 1837 to vote for county members was 5249. Of these, 3793 were freeholders, 131 leaseholders, 208 copyholders, and 1117 occupying tenants: being 1 in 29 of the whole population, and 1 in 7 of the male population twenty years of age and upwards, as taken in 1831.

Oxfordshire contains five savings' banks: the number of depositors and amount of deposits on the 20th of November, in each of the following years, were as under:—

	[illegible]	[illegible]	[illegible]	[illegible]
Number of depositors	[illegible]	[illegible]	[illegible]	[illegible]
Amount of deposits	[illegible]	[illegible]	[illegible]	[illegible]

The various sums placed in the savings' banks in 1836, 1837, and 1838, were distributed as under:—

	1836.		1837.		1838.	
	Depositors.	Deposits.	Depositors.	Deposits.	Depositors.	Deposits.

Education.—The following summary is taken from the Parliamentary Returns on Education made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant schools	68		
Number of children at such schools; ages from 2 to 7 years:—			
Males		335	
Females		374	
Sex not specified		602	
			1,311
Daily schools	510		
Number of children at such schools; ages from 4 to 14 years:—			
Males		6,450	
Females		5,730	
Sex not specified		2,378	
			14,558
Schools	578		
Total of children under daily instruction			15,869
Sunday schools	384		
Number of children at such schools; ages from 4 to 15 years:—			
Males		6,800	
Females		7,161	
Sex not specified		2,771	
			16,732

Assuming that the population between the ages of 2 and 15 years has increased in the same proportion as the whole of the population since 1821, and that the whole population has increased in the same ratio since 1831 as in the ten years preceding that time, the approximate number of children between the ages of 2 and 15 years thus found residing in Oxfordshire, in 1833, was about 51,732. Twenty-three Sunday-schools are returned from places where no other school exists, and the children, 765 in number, who are instructed therein cannot be supposed to attend any other school; at all other places Sunday-school children have opportunity of resorting to other schools also, but in what number or in what proportion duplicate entry is thus produced, must remain uncertain. Fifty-five schools, containing 3347 children, which are both daily and Sunday schools, are returned from various places, and duplicate entry is therefore known to have been thus far created. Making allowance for this uncertainty therefore, we may perhaps fairly estimate that little more than one-half of the children between the ages of 2 and 15 years are under instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscription and payment from scholars.

Daily Schools	71	[illegible]	[illegible]	[illegible]	361	[illegible]	[illegible]	[illegible]
Sunday Schools	10	[illegible]	236	14,455	—	—	[illegible]	[illegible]
Total	82	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

The schools established by Dissenters, included in the above statement, are—

		Scholars.
Infant-schools	1, containing	76
Daily-schools	11	561
Sunday-schools	57	3,823

The schools established since 1818 are—

Infant and other daily schools	264, containing	9,280
Sunday-schools	166	11,595

Thirty-nine boarding-schools are included in the number of daily-schools given above. No school in this county appears to be confined to the children of parents of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists and Roman Catholics.

Lending-libraries of books are attached to 25 schools in this county.

OXPECKERS. [Buphaga; Onyhovys.]

OXUS is the antient name of the river Amoo or Jihon. This river rises in the mountains which form the northern boundary of India, and flows into the Sea of Aral. According to most of the antient writers, it flowed direct into the Caspian; and this statement is said to be confirmed by the existence of its former channel. Herodotus speaks of this river under the name of Araxes (i. 201, 202, 205; iv. 11, 40); though it must be remarked that many commentators suppose that the Araxes of Herodotus is the river of the same name in Armenia; while others suppose that it is either the Volga or the Jaxartes. It appears almost certain however that this Araxes should be looked for in the east of the Caspian, though it would be difficult to determine whether it should be regarded as the same as the Oxus or the Jaxartes. Herodotus appears to have confounded it with the Araxes of Armenia, since he says that it rises in the country of the Matieni (i. 202) and flows towards the east (iv. 40). According to his account there were many islands in it, some as large as Lesbos, and it emptied itself by forty mouths, which were all lost in marshes, with the exception of one, which flowed into the Caspian (i. 202). Strabo says that the Oxus rose in the Indian mountains and flowed into the Caspian (Strabo, xi., p. 509, 519); which is also the opinion of Mela (iii. 5) and Ptolemy. Pliny (vi. 18) makes it rise in a lake called Oxus; but it is not improbable that, with his usual carelessness in matters relating to geography, he confounded its source with its termination.

The Oxus is a broad and rapid river, and receives many affluents, of which the most important mentioned by the antients was the Ochus, which, according to most accounts, flowed into the Oxus near its mouth; though, according to some, it flowed into the Caspian by a separate channel. (Strabo, xi. 509, 518.) There is however considerable difficulty in the statements of the antient writers on this subject. Strabo states that it rises in the same mountains as the Oxus (xi. 509); which must be a mistake, unless, as is probably the case, the Oxus and the Ochus are to be regarded as the same river.

The Oxus has exercised an important influence upon the history and civilization of Asia. It has in almost all ages formed the boundary between the great monarchies of south-western Asia and the wandering hordes of Scythia and Tartary. The conquests of Cyrus were terminated by its banks, and those of the Macedonians were few and unimportant beyond it. The Oxus appears to have formed one of the earliest channels for the conveyance of the produce of India to the western countries of Asia. Strabo informs us (xi., p. 509), on the authority of Aristobulus, that goods were conveyed from India down the Oxus to the Caspian, and were thence carried by the river Cyrus into Albania and the countries bordering on the Euxine. This account is also confirmed by the statement of Varro (quoted by Plin., vi. 19), who informs us that Pompey learned, in the war with Mithridates, that Indian goods were carried by the Oxus into the Caspian, and thence through the Caspian to the river Cyrus, from which river they were conveyed by a journey of five days to the river Phasis in Pontus.

The breadth of the Oxus immediately to the north of Balkh is 800 yards, and its depth 20 feet (Burnes's *Travels into Bokhara*, vol. i., p. 249); but south of Bokhara the river is only 650 yards wide, but from 25 to 29 feet deep. (Burnes, vol. ii., p. 5.)

OXYGEN, an elementary body, the properties of which are best known and most remarkable in its elastic or aëriform state, in which it is termed *Oxygen gas*. The most important discovery of this substance was made by Dr. Priestley on the 1st of August, 1774, and of his numerous contributions to chemical science, this is at once the most splendid and the most solid, and has rendered his name imperishable.

Dr. Priestley has stated, with his usual candour, that the discovery was also made, quite independently, though later, by Scheele, and he has refuted the unjust claim of Lavoisier to be also one of the discoverers of this element. To this gas Dr. Priestley gave the name of *dephlogisticated air*, Scheele called it *empyreal air*, and Condorcet *vital air*. Lavoisier gave it the name of *oxygen*, from the Greek words ὀξὺς, *acid*, and the root γεν, to *generate*, because he considered it as the sole cause of acidity; this appellation it still retains, although it is now well known that there are acids which do not contain it and alkalis which do.

Dr. Priestley first procured this gaseous body by heating the binoxide of mercury, then called *mercurius præcipitatus per se*, in an air-jar, over mercury, by means of a lens, and he afterwards obtained it from other substances.

It is now prepared in various ways, according to the purposes to which it is intended to be applied. These ways we shall briefly state and explain, and also describe the production of the gas from the binoxide of mercury, first used by Dr. Priestley.

When mercury is heated, and at the same time exposed to atmospheric air, it is found that the volume of the air is diminished, and the weight of the mercury increased, and that it becomes during the operation a red crystalline body, which is the binoxide of mercury, formed by the metal combining with the oxygen of the air.

When this substance is subjected in a retort to a higher temperature than that required for its formation, the affinity between the metal and the oxygen is overcome; the former returns to its metallic state, and the latter to its gaseous form; and if added to the residual atmospheric air, its volume is restored.

If it be quite pure, and the operation be accurately performed, 218 grains (1 equivalent) of binoxide of mercury should be separated by the agency of heat into 202 grains, one equivalent of mercury, and 16 grains, two equivalents of oxygen, measuring 46·5 cubic inches.

By this process then oxygen gas is, though indirectly, obtained from atmospheric air: but there is a natural metallic oxide, the *binoxide of manganese*, which is found plentifully, and which also yields it by the mere application of heat, and the quantity of gas obtained is dependent upon the degree of heat employed; in this case however, unlike that of the binoxide of mercury, the metal is not reduced. The equivalent of binoxide of manganese [MANGANESE] is 44, consisting of 28 of metal and 2 equivalents of oxygen = 16; and when 44 grains are heated to moderate redness in a coated glass retort, half an equivalent of oxygen, or 4 grains, measuring 11·62 cubic inches, are expelled, and there remains in the retort an equivalent of sesquioxide of manganese, composed of 28 metal and 12 oxygen = 40. But if the equivalent of binoxide be strongly heated in an iron retort, it is then converted into red oxide, consisting of one equivalent of metal, and one and one-third of oxygen, while two-thirds of an equivalent of oxygen are expelled, weighing 5·32 grains and measuring 15·5 cubic inches.

Another but less eligible method of obtaining oxygen from the binoxide of manganese, is to heat it with sulphuric acid in a retort; in this case an equivalent of the binoxide =44, loses a whole equivalent of oxygen = 8 grains, or 23·25 cubic inches, and there remain in the retort protoxide of manganese combined with the sulphuric acid, forming protosulphate of manganese. It is to be observed that these statements of the quantities of oxygen procurable from a given quantity of the binoxide of manganese are made on the supposition of its being quite pure, which is hardly ever the case; the binoxide of commerce very commonly contains 20 per cent. of impurity.

Red or deutoxide of lead also, when heated, either with or without sulphuric acid, yields oxygen gas, but the quantity obtained is small, and the processes are on several accounts ineligible. When nitrate of potash also is heated to redness, it gives out a considerable quantity of oxygen gas, from the decomposition of the nitric acid; but as it comes over mixed at different periods of the operation with variable quantities of the azotic gas of the nitric acid, this is not a method usually resorted to.

The oxygen gas obtained from binoxide of manganese is sufficiently pure for all the usual purposes of experiments intended merely to illustrate the properties of the gas; but when the gas is required for chemical analysis or accurate investigations, it is then obtained from the salt formerly called oxymuriate of potash, but now chlorate of potash.

Chlorate of potash is composed of one equivalent of chloric acid 76, and one of potash 48 = 124; and when 124 grains are heated in a retort, they are resolved into an equivalent of chloride of potassium 76, which remains in the retort, and 6 equivalents of oxygen, 5 from the acid and 1 from the potash = 48, which measure nearly 140 cubic inches, so that there is scarcely any other substance which yields so much oxygen gas or of so great purity.

Oxygen possesses great power of combination with other elementary bodies, there being scarcely one with which it is not known to combine either by direct union or indirect chemical action. The compounds to which it gives rise by combining, for example, with certain metals, and also indeed with some other bodies, may be classed under the three heads of oxides, acids, and alkalis. There are many bodies which, by a moderate degree of oxidation, become first oxides, and by an increased degree, acids; such substances are charcoal, phosphorus, chromium, &c.: but there is no instance of its forming with different proportions of the same element an acid and an alkali.

The properties of oxygen gas are, that it is devoid of colour, taste, or smell, and being transparent, it is also invisible. It possesses the mechanical properties of common air; it is capable of being respired, and a given volume of it will support life much longer than an equal bulk of common air; on this account the name of vital air was bestowed upon it. It is heavier than atmospheric air, 100 cubic inches at a medium temperature and pressure weighing 34·4 grains, whereas an equal volume of atmospheric air weighs 31 grains. It is but slightly soluble in water, requiring about 27 times its bulk for solution. Light has no effect upon this gas; by heat, like all gaseous bodies, it is merely expanded; and electricity is incapable of effecting any change in its properties. Oxygen gas has not been rendered either liquid or solid by the united agency of cold and pressure, and not having been divided into two or more kinds of matter, it is considered as elementary in its nature. Its equivalent, atomic or combining weight, is 8.

It will be proper here to notice the production of oxygen gas by the action of electricity, especially voltaic electricity, which, as is well known, possesses the power of evolving both oxygen and hydrogen from water. Oxygen gas is also evolved by the action of the sun's rays on the moistened leaves of trees, which by this agency decompose the carbonic acid diffused in the atmosphere from various sources, and by combining it with their carbon, flourish and increase in size. When compounds containing oxygen are decomposed by voltaic electricity, the oxygen is evolved in the gaseous state at the anode or positive pole.

The most remarkable property of oxygen gas, and that on account of which it has been called *fire-air*, is the facility and splendour with which bodies, when previously ignited, burn in it. Substances which do not undergo combustion in the air, will readily do so, and with great brilliancy, in oxygen gas; iron for example burns very readily in it when previously made red-hot. The intensity of the light emitted by burning phosphorus in oxygen gas is such as to be scarcely tolerable.

In conclusion, we may remark, that until after the discovery of this gas nothing was or could be known respecting the nature of the air, of water, or of earth, all of which, formerly reckoned as elementary bodies, are now known to be compound, and to contain oxygen as one of their constituents. It has also thrown great and unexpected light on the nature of combustion and respiration.

The compounds which oxygen forms with metals and other elementary bodies, are treated of under their respective heads, whether they are oxides, acids, or alkalis.

OXYLOPHUS. [CUCULIDÆ, vol. viii., p. 209.]

OXYMURIATIC ACID. [CHLORINE.]

OXYNOTUS, Mr. Swainson's name for a genus of *Ceblepyrinæ*, or *Caterpillar-Catchers*. [SHRIKES.]

OXYRHYNCHS, a name given by M. Latreille to a great division of Brachyurous crustaceans, consisting of the *Notopodes*, the *Oxystomes*, and many of the *Anomoures* (Anomourous) of M. Milne Edwards. The latter zoologist however remarks that as the classification in which the term was employed has been long abandoned even by its author, he (M. Milne Edwards) had thought that it would not be inconvenient to apply it to the family about to be noticed, and so avoid the necessity of adding a new name to zoological nomenclature, which is already so vast.

The natural group, then, to which M. Milne Edwards applies the name '*Oxyrhinques*' is that which presents a nervous system more centralised than he has as yet discovered among the crustaceans, and it is principally for that reason that he places the Oxyrhynchs at the head of the series formed by these animals. In fact, he observes, the different medullary ganglions of the thorax do not, in this instance, form more than a single solid mass in the form of a disk, whilst in the other Decapods, of which the internal anatomy is known, these same ganglions remain more or less distinct, and only unite so as to form a circular ring. In many of the Oxyrhynchs, M. Milne Edwards has also remarked that the two portions of the *liver*, instead of being completely separated as in the other Decapods, are united on the median line by an unequal lobe: this viscus is well developed and extends over a great part of the vault of the branchial cavity. The number of *branchiæ* is always nine on each side of the thorax; seven of these organs, the last of which is inserted above the third foot, are very much developed, and rest on the vault of the sides, whilst the two others are often reduced to the rudimentary state, and are hidden at the base of the first. Lastly, the vault of the *respiratory cavity* is but slightly elevated, and, throughout its extent, nearly comes in contact with the upper surface of the branchiæ. The rest of the internal organization offers nothing peculiar.

But the same assertion cannot be made with regard to the external organization of these animals. The general form of their body approximates to that of a triangle, of which the base is rounded and turned backwards. The *carapace* is nearly always very unequal, rough with spines or hairs, and remarkably longer than it is wide; the regions, with the exception of the hepatic, are ordinarily distinct; the stomachal region is nearly always longer than it is wide, although it occupies all the width of the post-orbital part of the carapace, and is never divided into two on the median line by a nearly linear prolongation of the genital region, as is seen in the greater number of the *Cyclometopes* and the *Catometopes*. The last-named region is, in general, but little developed, and is confounded more or less completely with the stomachal region, or is truncated anteriorly. The hepatic regions are rudimentary and indistinct, but the branchial regions are very much developed, and extend beyond the edge of the anterior border of the sternal plastron; they are convex, and it is always towards their middle that the carapace presents the greatest width. Nothing particular is observable in the cardial and intestinal regions. The *front* is always narrow, and, in general, advanced so as to constitute a very projecting *rostrum*. The *orbits* are directed more or less obliquely outwards, and are often so small and so little in proportion to the length of the ocular stems, that those organs cannot bend back; the post-foraminal portion of these cavities is rather deep, and extends, as usual, rather far outwards, that the eyes may be entirely hidden therein. The *antennæ* of the first pair exhibit nothing remarkable in form; but their moveable stem is fairly developed; they bend back, nearly always, longitudinally, and are lodged in receptacles equally longitudinal and completely separated from the *orbital cavities*. In nearly all the *Brachyura* the first joint of the external antennæ is extremely developed, and completely soldered to the front and to the neighbouring parts of the pterygostomian regions; it constitutes a considerable portion of the lower wall of the orbit, and presents at its base a circular aperture, which is filled by a calcareous disk belonging to the auditory apparatus; the two succeeding joints are, in general, perfectly free, and support a rather long terminal stem. The *epistome* is, in general, nearly square; the *antennary region* very much developed, and the edge of the *buccal frame*, which terminates it posteriorly, is nearly straight and projects much. The *pterygostomian regions*, on the contrary, are not extended, and are in general rather clearly divided into two portions, one corresponding with the efferent canal of the respiratory cavity, and the other situated in front of and outside the first; finally, the curved line which indicates the point of junction of the dorsal piece of the carapace with the lateral flaws, terminates towards the base of the third foot. The *external jaw-feet* never reach beyond the anterior border of the buccal frame; their first joint is large, and serves as a valvule to close the aperture which is seen immediately before the anterior feet, and conducts to the branchial cavity; it supports at its internal extremity a palp and a stem, of which the two first joints are very large and cover the rest of the buccal apparatus, of which the three last pieces are by much the least: the general form of this species of opercula varies, but is never triangular. The *jaw-feet* of the second pair present nothing remarkable; the first joint of the palp of those of the third is always longer than the corneous blade, which represents the external portion of the stem. The other appendages of the mouth offer nothing particular. In general, the *sternal plastron* is nearly circular, and the space which separates the posterior feet inconsiderable. The median *apodeme* of the thorax ordinarily only occupies the last ring: the sella Turcica is not much elevated, and the sternal *apodemes*, which separate the corresponding cells from the external jaw-feet and the thoracic three first pair, are far from extending near to the median line of the body. The first pair of *feet* are generally of the same size on each side; but their dimensions are very different in some species and also in the sexes. The succeeding feet are often of enormous length, and are nearly always slender and cylindrical; this disposition is even carried so far in some of the Oxyrhynchs that it has obtained for them the name of *Sea-spiders*. The second or third last pairs are sometimes subcheliform; but these organs never take the form of natatory fins, and in general those of the three last pairs diminish gradually in length.

It is in the basilary joint of the posterior feet that the apertures which give a passage to the intromissive organs of the male are situated: these organs are in immediate relationship with the abdominal members, and are never lodged in a transversal canal of the sternum. The disposition of the *abdomen* varies much; sometimes it presents seven distinct pieces; sometimes that of the female only offers six, five, or even four; whilst that of the males remains composed of seven separate rings; sometimes the males have only six segments. It is also worthy of note that in the males the space comprised between the posterior feet is entirely covered by the abdomen. With regard to the appendages of this part of the body, they present nothing particular in the female, and in the male those of the first pair are in general slender, styliform, truncated at the end, nearly straight, and rather long; whilst those of the second pair are rudimentary.

Habits, Food, &c.—The Oxyrhynchs are all essentially marine. None are known to live in fresh-water or to frequent the shores of the sea; but all inhabit great depths, and are generally obtained when dredging for large fish. Their long feet would convey an idea of nimbleness, but these crustacea are in general slow in their motions, and soon die out of water. No swimmers are known among them.

⁂ No fossil Oxyrhynchs have as yet been detected.

(M. Edwards.) M. Milne Edwards divides this family, which embraces a considerable number of genera, into three tribes—the *Macropodians*, the *Maians* or *Maiadæ*, and the *Parthenopians*. The reader will find the two first treated of in this work under their respective titles, and the *Parthenopians* will be described under that name.

OXYRHYNCHUS, M. Temminck's name for a genus of birds placed by Mr. Swainson under the family *Picidæ*. [Woodpeckers.]

OXYRHYNCHUS. [Egypt.]

OXY'STOMA. The *Oxystomes* of M. de Blainville form the fifth family of his *Asiphonobranchiata*. [Janthina.]

OXYSTOMES, the name applied by M. Milne Edwards to the fourth and last family of Brachyurous crustaceans (type, *Leucosia*, Fabr.), comprising all the crustacea which most resemble the type in their general organization, and especially in the conformation of the buccal apparatus.

The apertures for the passage of the intromissive organs of the males are hollowed out in the basilary joint of the posterior feet, as in the Oxyrhynchs and the Cyclometopes. The disposition of the branchiæ is also nearly the same as in the last-named group, but sometimes the number of these organs is less considerable, and does not amount to more than six on each side. In most of these crustaceans the branchial cavity does not present at the base of the feet any aperture for the entrance of the water necessary for respiration, and this liquid only arrives there by a gutter hollowed out on each side of the prelabial space, serving as a passage for the water expelled from the branchial cavity. This canal is very long in nearly all the Oxystomes, and is converted into a species of tube by a prolongation of the anterior jaw-feet. The internal soft parts have not as yet been discovered to present any particular organization.

The *Carapace* is generally more or less circular, but sometimes it is curved anteriorly only, and much resembles that of some of the Cyclometopes. The *eyes* are ordinarily small. The disposition of the *antennæ* varies, but in most cases the region occupied by these appendages is of small extent. The *buccal frame* is in most of the family entirely triangular, and terminates anteriorly by a narrow summit, which is much prolonged, often to a level with the eyes and close to the front. The external *jaw-feet* which fill this have also ordinarily the form of an elongated triangle, and do not permit the terminal stemlet to be perceived externally; they advance then near to the extremity of the buccal frame, but never reach it, so that there is always at this point a gaping aperture which serves for the passage of the water necessary for respiration; in other cases the external jaw-feet are much shorter than the buccal frame; the lamellar appendage of the *internal jaw-feet* much exceeds it, and their third joint, which is narrow and more or less tapered anteriorly, does not cover the three small terminal joints. The *anterior feet* are nearly always short, and in the greater part of the family the hand is compressed, more or less elevated above in the form of a crest, and disposed so as to be capable of exact application against the buccal frame. M. Milne Edwards divides the family into the following tribes—the *Leucosians*, the *Calappians*, the *Corystians*, and the *Dorippians*.

Leucosians. (M. Edwards.)

Carapace, in general circular, presenting anteriorly a rather strong projection, at the extremity of which is often found the front and the orbits. *Front* narrow, and orbital cavities very small and nearly circular. The *internal antennæ* bend back nearly always transversely or very obliquely under the front; and the *external antennæ*, which are inserted in a narrow but deep notch of the orbitary internal angle, are nearly rudimentary. The *buccal frame* is in general regularly triangular, and the external *jaw-feet* of the same form do not show uncovered the stemlet which supports their third joint; the palp or lateral branch of these organs is very large, and their base is separated from that of the anterior feet by a prolongation of the pterygostomian region, which is soldered into the sternal plastron. The result is that the aperture situated ordinarily at this point, and serving for the entrance of the water into the respiratory cavity, is here wanting, and that liquid only arrives at the branchiæ by means of two canals hollowed on each side of the prelabial space and parallel to the efferent canals of the respiratory cavity. The second pair of jaw-feet present nothing remarkable; but the first pair have the terminal joint of their stem lamellar, and sufficiently long to arrive at the anterior extremity of the buccal frame.

The *sternal plastron* is nearly circular, and the legs are slender. The number of abdominal joints is three or four. (M. E.)

M. Milne Edwards arranges the following genera under this tribe—*Arcania*, *Philyra*, *Myra*, *Ilia Guaia*, *Leucosia*, *Persephona*, *Nursia*, *Ebalia*, *Oreophorus*, *Iphis*, and *Ixa*. We shall endeavour to illustrate two of these genera in a subsequent part of the work.

Calappians.

Carapace sometimes circular, sometimes very much widened, and always more or less convex. *Front* of moderate width, and the lateral borders of the carapace delicate and more or less dentilated. *External antennæ* small, but very distinct. External or first pair of *feet* strong, compressed, curved so as to apply themselves against the buccal region, and armed above with a more or less elevated crest. The apertures by which the water arrives in the respiratory cavities are disposed in the ordinary manner in front of the base of the anterior feet, and the number of branchiæ is normal.

The genera arranged by M. Milne Edwards under this tribe are, *Calappa*, *Platymera*, *Mursia*, *Orythia*, *Matuta*, and *Hepatus*. *Calappa* and *Hepatus* have already been illustrated in this work.

Corystians.

M. Milne Edwards is of opinion that the crustaceans which compose this group establish the passage between the Cancerians and the Calappians on one side, and the Anurous Decapods (*Decapodes Anoures*) on the other. The *buccal frame* is not so narrow anteriorly as it is in the greater part of the *Oxystomes*, and the *jaw-feet* do not close it exactly. The *external antennæ* are very large, and the *sternal plastron* is very narrow.

The following genera come under this tribe in the system of M. Milne Edwards: *Atelycyclus*, *Thia*, *Polydectus*, *Corystes*, *Nautilocorystes*, and *Pseudocorystes*. Of these genera, *Corystes* has already been described and illustrated in this work.

Dorippians.

Carapace very much depressed, truncated anteriorly, a little widened behind, nearly quadrilateral, and in general too short to cover the whole body. *Front* wide; eyes of the ordinary size. Disposition of the *mouth* approximating nearly to that in *Calappa*, *Mursia*, &c. The water reaches the branchiæ by two apertures situated in front of the base of the anterior feet. The *sternal plastron* is circular and strongly recurved up towards its posterior part. The *anterior feet* are short; those of the two succeeding pairs are long and terminated by a styliform joint. The last or the two last pair are inserted above the others, upon the back, so to speak, and are nearly always much smaller than the preceding: they are terminated in general by a hooked joint, so disposed as to be capable of acting as a prehensile organ. (M. E.)

M. Milne Edwards arranges the following genera under this tribe: *Dorippe*, *Cymopolia*, *Caphyra*, and *Ethusa*. Of these, *Dorippe* and *Ethusa* have been already described and illustrated in this work.

OXY'STOMUS, Mr. Swainson's name for a genus of birds arranged by him among the typical *Starlings*. [Sturnidæ.]

OXYU'RUS, Mr. Swainson's name for a genus of birds placed by him under the subfamily *Certhianæ*, with the following

Generic Character.—Bill short, straight, very slender, resembling that of a *Sylvia*; the sides compressed and the margin inflexed; the tips entire. Wings rather lengthened; the outer quills graduated, the fourth and fifth equal. Feet large. Middle toe of the same length as the hinder; lateral toes unequal, the outer connected to the middle as far as the first point; inner toe shortest. Tail graduated, rigid: the inner web broad, and abruptly sinuated at the end; outer web very narrow; tips of the shafts hard and naked as in *Dendrocolaptes*.

Locality.—South America. (Sw.)

Examples, *Oxyurus ornatus* and *Oxyurus Australis*. (Lath., 'Syn.')

OYER AND TERMINER. These words in antient law French denote a commission forming a court of criminal judicature, the distinguishing character of which is described by them. The substance of the commission, or writ as it was anciently called, is an authority given by the king to certain persons judicially to *hear and determine* (*oyer et terminer*) certain specified offences. The commissions of oyer and terminer are the most comprehensive of the several commissions which constitute the authority of the judges of assize on the circuits. On these occasions they are usually directed to the lord chancellor, several high officers of state, two judges of the courts of Westminster, the king's counsel, the serjeants-at-law, and the associates; but (excepting on the Northern Circuit, where all the commissioners but one are of the *quorum*) the judges, king's counsel, and serjeants are always of the *quorum*, so that the other commissioners cannot act without the presence of one of them. Justices of oyer and terminer at the assizes have, by the terms of their commissions, jurisdiction to inquire into the truth of all treasons, misprisions of treason, felonies, and misdemeanors committed within the several counties and places which constitute their circuits, and also to *hear and determine* the same on certain days and at certain places to be appointed by themselves. Besides these ordinary courts of oyer and terminer at the assizes, special commissions of oyer and terminer are sometimes issued upon urgent occasions where offences of a dangerous tendency have been committed in particular districts, and where the public peace and security require immediate inquiry and punishment. So also special commissions have been sometimes issued where from particular circumstances the incompetency of the ordinary tribunals would occasion a failure of justice. A remarkable instance of this kind occurred when Mr. Dunning, afterwards Lord Ashburton, was recorder of Bristol and sole criminal judge under the charters of the city. A forgery of Mr. Dunning's name to a bill of exchange having been committed in Bristol, he properly refused to try a case in which he was a party interested, and it was therefore necessary to issue a special commission for the purpose of hearing and determining this single offence. Upon special commissions of oyer and terminer the course of the proceedings is nearly the same as upon ordinary or general commissions.

OYSTER-CATCHER. [SEA-PIE.]

OYSTERS, or OSTRACEANS, a family of monomyarian conchifers. According to Lamarck, the definition of the family is, 'Ligament interior or demi-interior. Shell irregular and foliated, sometimes papyraceous.'

Linnæus defined his genus *Ostrea* as '*Animal* Tethys. *Shell* bivalve, inequivalve, subauriculated. *Hinge* edentulous, with a hollow ovate little excavation and lateral transverse striæ;' and he divided the genus into the following sections:—

* Pectines auriculati, æquilateri.

Under this section come those Pectens which have nearly equilateral auriculations, as *Pecten maximus, Jacobæus, Ziczac, minuta, Pleuronectes, Radula, Pica.*

** Pectines auriculâ alterâ intus ciliato spinosa.

Under which are arranged *Pecten Pallium, nodosus, Pes felis, pellucens, obliterata, sanguinea, varia, Pusio, glabra, opercularis, gibba.*

*** Pectines valvulis altero latere magis gibbis,

consisting of *P.* [illegible], [illegible], *Lima.*

**** Rudes, vulgo Ostreæ dictæ,

comprising *Ostrea Malleus,* [illegible], *Folium, orbicularis,* [illegible], *Perna, Isognomum,* and *Ephippium.*

Lamarck's *Pectinides* consisted of the genera *Pedum, Lima, Plagiostoma, Pecten, Plicatula, Spondylus,* and *Podopsis.*

The Ostraceans of the same author consist of the genera *Gryphæa, Ostrea, Vulsella, Placuna,* and *Anomia.*

Cuvier, under his *Huîtres* (Ostrea, Linn.), arranges *Ostrea, Gryphæa, Pecten, Lima,* and *Pedum*; and he adds, that the following fossil genera—*Dianchora, Plagiostoma,* *Podopsis,* [illegible], and [illegible], might here find a place.

Appertaining to the Oysters, although multivalve, should be, in his opinion, the *Anomia* of Bruguière. He then proceeds to *Placuna*, a genus related to *Anomia*, and makes the Thorny Oysters, *Spondylus*, Linn. (with *Plicatula*, Lamarck), follow. To these succeed *Malleus, Vulsella, Perna,* &c.

The Ostraceans of M. de Blainville consist of *Anomia, Placuna, Harpax, Ostrea,* and *Gryphæa*) and his *Subostraceans*, of the genera [illegible], *Spondylus, Plicatula, Hinnites, Pecten, Pedum,* and *Lima.*

Of these arrangements that of Linnæus, to a certain extent, appears to us as natural as any; and the *Oysters*, properly so called, *Pectens*, and *Limæ*, are treated of in this work under the article PECTINIDÆ. We see no good reason why *Gryphæa* (*Anomia Gryphus*, Linn.) and *Anomia* should not be associated with that family.

OZANAM, JACQUES, was born in the year 1640, at Bouligneux, in the present department of the Ain. His family, though of Jewish extraction, had long been members of the Roman Catholic Church; and his father was possessed of considerable landed property, to which some ecclesiastical patronage was attached. Jacques, being the younger of two sons, was designed for the church, and accordingly began the necessary studies, but less from his own inclination than to comply with the wishes of his father. His biographers describe him as naturally pious, generous, witty, and gallant; but he certainly was too tolerant for a churchman of his day. The theological writings to which his attention was directed gave him little satisfaction. Other subjects of investigation, such as chemistry, mechanics, &c., which seemed to admit of more useful application, attracted his notice, and thenceforward his theological studies were attended to solely from compulsion or a sense of duty. The tutor to whose care he had been confided possessed some slight acquaintance with the mathematics, and from him he may have received some assistance in reading them; but, with this exception, he was self-taught; and although he never attained to any great eminence as a mathematician, he was the author of several useful works, which became extremely popular, and passed through many editions.

The death of his father, which took place about four years after he commenced reading for the church, left him free to follow whatever occupation he chose. He accordingly removed to Lyon, where he began teaching the mathematics gratuitously, regarding it as a degradation to receive payment for his instruction. It is probable that he did not long act under this impression, as his pecuniary means were limited, and his attachment to games of chance frequently led him to the gaming-table.

At the invitation of the chancellor of France, he removed to the French capital, where his amours soon drew so heavily upon his resources, that he determined upon marrying, as the most effectual way of curtailing his expenditure. His wife was without fortune, but possessed of so many excellent qualities, that his greatest affliction was occasioned by her death in 1701. By her he had twelve children. At Paris he had for many years considerable success as a mathematical tutor, though he was patronised much more by foreigners than by his own countrymen. Most of the former were obliged to leave the country upon the breaking out of the war of the Spanish Succession, the same year as that in which his wife died; and from that time, the income he derived from his profession was both small and uncertain. Montucla, speaking of his scientific productions, remarks, 'He promoted the mathematics by his treatise upon lines of the second order; and had he pursued the same branch of research, he would have acquired a more solid reputation than by the publication of his "Course," "Recreations," or "Mathematical Dictionary;" but having to look to the support of himself and family, he wisely consulted the taste of his purchasers rather than his own.' (*Histoire des Mathém.*, ii., p. 168.) When far advanced in years he was admitted an élève of the Academy of Sciences, and died at Paris, of apoplexy, April 3, 1717. The following is a list of his works, in the order of publication:—

1, 'Méthode pour tracer les Cadrans,' 8vo., Paris, 1673-85-1730; 2, 'Géométrie pratique,' 12mo., Paris, 1684-89-1736-64; 3, 'Tables des Sinus, Tangentes, &c.,' 8vo., Paris, 1685-1720-41; 4, 'Traité des Lignes du premier genre,' 8vo., Paris, 1687; 5, 'Usage de l'Instrument universel pour résoudre promptement tous les Problèmes de la Géométrie pratique,' 12mo., Paris, 1688, 1700-36-48-94 (the instrument referred to is the proportional compass); 6, 'Méthode de lever les Plans et les Cartes de Terre et de Mer,' 12mo., Paris, 1693-1750 (the same improved by Audierne, 12mo., Paris, 1782); 7, 'Dictionnaire Mathématique,' 4to., Amst., 1691 (the same translated and abridged by Raphson, 8vo., London, 1702); 8, 'Cours de Mathématique,' 5 vols. 8vo., Paris, 1693, Amst., 1699; 9, 'Récréations mathématiques et physiques,' 4 vols. 8vo., Paris, 1694-1720-25-35-77 (the same improved and augmented by Montucla, 8vo., Paris, 1778-90; the same in English by Dr. Hutton, 8vo., Lond., 1803); 10, 'Traité de la Fortification,' 8vo., Paris, 1694-1720 (the same translated by Desaguliers, 8vo., Oxf., Lond., 1711); 11, 'Trigonométrie,' 12mo., Paris, 1698; 12, 'Méthode facile pour arpenter et mesurer toutes sortes de Superficies, &c.,' 12mo., Paris, 1699-1725-47-58-79; 13, 'Elémens d'Algèbre,' 8vo., Amst., 1702; 14, 'Géographie et Cosmographie,' 8vo., Paris, 1711; 15, 'La Perspective, théorique et pratique,' 8vo., Paris, 1711-20. In the 'Memoirs of the Academy of Sciences' for 1707 there is a paper by him entitled 'Observations sur un Problème de Trigonométrie spherique.' To the 'Journal des Savans' he contributed: 1, 'Proof of the Theorem that neither the sum nor the difference of two fourth powers can be a fourth power,' May, 1680; 2, 'Answer to a Problem proposed by M. Comiers,' Nov., 1681; 3, 'Proof of a Theorem relative to Imaginary Roots,' April, 1683; 4, 'Method of determining the cubic and sursolid roots of a Binomial.' At his death he left a treatise in MS. upon the Diophantine Analysis, which came into the possession of M. Aguesseau. He also published a corrected and augmented edition of Vlacq's 'Trigonometry,' 8vo., Paris, 1720-65.

(*Eloge, par Fontenelle*; *Œuvres diverses*, La Haye, 1728-29, fol. iii., p. [illegible]; *Biographie Universelle*; &c.)

OZARK MOUNTAINS, THE, constitute an extensive mountain region in the United States of America, west of the Mississippi. They occupy more than half the state of Arkansas and a considerable portion of the state of Missouri south of the Missouri river. Their northern extremity forms the elevated shores of the Missouri river between the mouths of the Osage and Gasconade rivers, where the river begins to run eastward: the hilly country also, which extends between the confluence of the Missouri and Mississippi, and along the west side of the latter river to Cape Girardeau, may be considered as the eastern declivity of the northern portion of this mountain region. The mountains extend south-west from the banks of the Missouri to the banks of the Arkansas river, which may be considered as breaking through the region south of the Arkansas river a mountainous country extends as far south as the Red River. It is not known if the elevated tract which runs along the southern banks of the last mentioned river, and in which the numerous rivers of Texas have their origin, is so connected with the Ozark Mountains that it may be considered as a portion of them. But this seems to be the only continuous elevated ground which unites the Ozarks with the Chippewyan or Rocky Mountains.

This mountain region extends, from south-west to north-east, from the Red River to the Missouri, more than 350 miles in length. If the country about the upper branches of White River, which is covered with high hills, is considered as a portion of the Ozarks, their width from west to east cannot fall short of 100 miles. Thus the Ozarks cover a surface of rather more than 36,000 square miles, or more than two thirds of the area of England, between 90° and 97° W. long. and between 34° and 39° N. lat.

The Ozarks, unlike the Apallachian Mountains, do not consist of parallel ridges. It seems that it is only towards the western edge of the mountain region that a continuous ridge occurs.

At the northern extremity, near the mouth of the Gasconade river, this range is of moderate elevation, hardly exceeding 500 or 600 feet above the sea-level, but its elevation increases farther south. Its highest point is about the sources of the White and Osage rivers, the two most considerable rivers which originate in these mountains. Farther south the range again decreases in elevation, until it terminates on the Arkansas west of Fort Smith, in some tolerably high hills. The mountains between the Arkansas and Red River form a continuous range, running east and west, and the highest summits, Mount Cerne, the Sugar-Loaf Mountains, and Cavaniol Mountain, attain an elevation of between 2000 and 3000 feet above the sea-level. The last-mentioned range is called the Masserne Mountains.

The country north of the Masserne Mountains and east running along the western edge of the Ozarks, vered with high hills, which extend eastward wn from the eastern extremity of the Masserne Mountains, near Little Rock or Arkopolis in Arkansas, to the town of St. Genevieve on the Mississippi (38° N. lat.). This extensive region, which constitutes the eastern broad slope of the Ozark, has an extremely broken surface. The hills and mountains, which are scattered over it in confusion, rise from 800 to 1800 feet above the sea-level, and from 500 to 1500 feet above their base. They are exceedingly numerous, and are divided into a multiplicity of knobs and peaks, which have rounded summits, and descend with perpendicular cliffs and abrupt precipices. Sandstone is the principal component of these mountains, but their surface is frequently strewed with a profusion of flinty fragments, and in many places it is covered by compact limestone. The hills, which are covered with limestone, contain forests of pine and cedar; those of sandstone are usually overgrown with scrub oak, hiccory, haws, and brambles. The poverty of the soil in some instances and the scarcity of it in others prevent a more luxuriant vegetation from springing up. The valleys between these hills are rather narrow, but have uniformly a fertile soil. They are however occasionally subject to excessive floods, which are brought down from the mountains by the rivers, a circumstance which renders their cultivation very precarious.

As this extensive mountain region has been very imperfectly explored, we are not acquainted with its mineral wealth. Coal and iron certainly occur in many places. Copper-ore has also been observed. Lead is abundant, especially towards the most north-eastern extremity of the region, which contains the rich lead-mines near Potosi in Missouri. [MISSOURI.] Rock-salt appears to occur in the Masserne Mountains; abundant salt-springs are found on the upper branches of the Washita river. These parts also contain hot-springs. [ARKANSAS.]

The origin of the word Ozarks seems rather doubtful. It does not appear to be a pure Indian form. It has been conjectured that it is derived from the French expression, 'Aux Arkansas,' abbreviated into 'Aux Ark,' the pronunciation of which is exactly represented in the English language by 'Ozark.'

(James's *Account of an Expedition to the Rocky Mountains, performed by Major Long*; and Nuttal's *Arkansas*.)

OZEROV, VLADISLAV ALEXANDROVITCH, the most distinguished tragic poet that Russia has hitherto produced, was born in the government of Tver, Sept. 29 (Oct. 11), 1770. After passing through the usual course of military service, in which, besides otherwise distinguishing himself, he rose to the rank of major-general, he exchanged it for a civil appointment, which he held till 1807, when he retired from public life. Instead however of devoting himself the more closely to his literary studies, he shortly after abandoned them, or at least discontinued writing, 'Polyxena,' which was first performed in May, 1809, being his last dramatic production. From that time to his death, which happened in November, 1816, he only composed three acts of an unfinished tragedy, entitled 'Medea,' and sketched the plans of two others, one of which had for its subject the siege of Damascus, and is said to have been founded on Hughes's English tragedy of the same name.

After a long and very severe illness, he was carried off at the age of forty-six.

All that can be gathered from what Prince Viazemsky says in his memoir of him, as to the cause of his doing nothing for so many years, is, that he was disgusted with the world on account of the mean enmity which his talents had raised up against him, though his productions had been most favourably received by the public.

Although the pieces upon which his fame rests do not amount to more than four, his first drama, entitled 'The Death of Oleg,' bearing no comparison with his succeeding ones, Ozerov may be considered not merely as the reformer, but as in a manner the creator of Russian tragedy. Kniazhin had improved upon Sumarokov, but chiefly in regard to style and manner: neither genuine poetry nor masterly delineation of character is to be met with in their tragedies. It was reserved for Ozerov to infuse vitality into the previously cold and lifeless form. His 'Œdipus,' 'Fingal,' Demetrii Donskoi,' and 'Polyxena,' are all severally masterpieces, full of poetry; and although simple in plan, and with more of dialogue than action, strikingly dramatic in some of the situations.

P.

P is the tenuis or thin letter of the labial series. For the various symbols employed to denote this letter see ALPHABET.

This letter is interchangeable with those which belong to the same organ, that is, the lips, and with some others. Thus

1. P is convertible with *b*. The Latin, like the Welsh, was fond of the thin letters, in consequence of which there are very few words in that language which begin with a *b*, while those commencing with *p* form a numerous class. It will often be found that the *p* in Latin words becomes a *b* in the related languages. Thus *apicula*, the diminutive of *apis*, a bee, is in French *abeille*; *septem* is in German *sieben*. The German language often confounds *b* and *p*, more particularly when the former is final. Perhaps, too, even in Latin, the written *b* was pronounced as a *p* in the prepositions *ab*, *sub*, *ob*, which correspond to the Greek ἀπο, ὑπο, ἐπι.

2. *P* with *m*, somewhat rare. Thus the Greek preposition μετα is in the Æolic dialect πεδα. Again, the Greek μολυβδος is essentially the same word with the Latin *plumbum*. Allied to this change is the insertion of a *p* between either *m* and *s* or *m* and *t*, as in the Latin *sumpsi*, *sumptus*, for *sumsi*, *sumtus*, and *temptare* for *tentare*.

3. *P* with *v*. This change is more particularly to be observed in the derivation of French from Latin. Thus from *capillus*, hair, *episcopus*, a bishop, *decipere*, deceive, &c., *aperire*, open, *opera*, work, *lepus*, hare, *pauper*, poor, *piper*, pepper, *Aprilis*, April, the French have deduced their *cheveu*, *evêque*, *decevoir*, &c., *ouvrir*, *œuvre*, *lièvre*, *pauvre*, *poivre*, *Avril*.

4. *P* with *f*. Two or three examples are given under F. To these may be added *pro*, *for*; *pater*, *father*; *piscis*, *fish*; *pauci*, *few*; *lupus*, *wolf*. So the Greek πορφυρα, πομφολυξ, Φοινιξ, have the aspirate, while the Latin, as usual, prefers the tenuis in *purpura*, *pustula*, *Poenus*.

5. *P* with *pf*. The latter form is often preferred by the German, where our own tongue has the single letter. Thus the English words *pound*, *peach*, *pepper*, *pea-cock*, *penny*, *apple*, are written by the Germans *pfund*, *pfirsche*, *pfeffer*, *pfau*, *pfennig*, *apfel*.

6. *P* with *c*, *k*, or *q*. See C.

7. *P* with *t*, as πως, in Latin *quo*. The Greek interrogative words beginning with a π, as πως, πη, ποτερος, &c., are related on the one hand to the Ionic forms κως, κη, κοτερος, and on the other to the demonstratives that commonly take a τ at the beginning. And in fact the latter are often used as relatives.

8. *P* with *pt*. The latter is common in Greek, as in τυπτω, κοπτω, &c., which form their other tenses for the most part without a τ. So too at the beginning of words. Thus πτολις and πτολεμος coexist with πολις and πολεμος; and it seems probable that it was an unsuccessful attempt to pronounce the initial *pt* which led to the formation of the Latin words *populus*, a state, and *populari*, to devastate with war.

9. *Ps* with *sp*. This change it will be more convenient to consider under the letter S.

10. *Pi* before a vowel with *ch*. Thus *sapiam*, in Latin, becomes *sache* in French. The word *roche*, too, was probably formed from a barbarous Latin word *rupia*; and *Rutupiae*, in the county of Kent, appears upon this principle to have changed its name to *Rich*-borough.

PAAMUTO ISLANDS. This is the native name of a great number of islands, or rather clusters of islands, scattered in the Pacific Ocean between 13° and 23° S. lat. and 130° and 150° W. long. On our charts they bear the name of the Dangerous Archipelago.

These islands are very numerous, and it is supposed that all of them have not been seen by Europeans. They constitute, according to Capt. Fitzroy, between seventy and eighty groups. Each group surrounds a lagoon, and is based on the coral reefs which enclose the lagoon. The islands are very little above the level of the sea. Their form is generally that of a crescent, the convex side being turned to the trade-winds. The highest part of the islands is in most cases on the most eastern part of the curvature, but it rarely exceeds six feet above high-water mark. The coral reefs which surround the lagoon have usually one opening or more, by which the enclosed sea may be entered. By far the largest number of these groups have at least one harbour in each cluster accessible to shipping; and a considerable trade has been carried on with the natives for pearl oyster-shells. Fish and shell-fish, hogs, and cocoa-nuts are the principal sources of subsistence to the natives. The natives are of the Malay race, and resemble the Otaheitans in person and language, though the languages differ so much that the Otaheitans and they do not easily understand one another. The question has often been asked, how the Malays could have spread to these remote lands against the direction of the trade-wind. Capt. Fitzroy solves this problem by stating that during the settled weather and a steady trade-wind (south-easterly) the surface waters in general move westward from five to twenty miles a day; but that in the rainy season from October to March, when westerly winds, squalls, and rain are frequent, the currents vary considerably, and occasionally set *eastward*, at the rate of from half a mile to two miles an hour. Thus it happens that canoes are drifted out of their course even several hundred miles by currents and westerly winds. The same seaman estimates the population of these islands at not less than 10,000, and not more than 20,000, exclusive of children; but he found them less advanced in civilisation than the inhabitants of the mountainous islands. The inhabitants of the Paamuto Islands, which are not very remote from Otaheite, receive laws from the sovereign of Otaheite; they have however no resident authority among them except the head of each family. The navigation between these islands is very dangerous, as many coral reefs, which are either dry or only just covered with water, are dispersed among them, and the sea surrounding the lagoons has no soundings.

(Fitzroy, in the *Narrative of the Surveying Voyages of the Adventure and Beagle*; Beechey, *Voyage to the Pacific and Behring's Strait*; Krusenstern's *Mémoires*, &c.)

PACA. [CŒLOGENYS.]

PACE (*Passus*), a measure of the Roman system, being in fact their unit of itinerary measure, to which the *mille passus*, or MILE, was referred. The word *passus* is connected with the root of *pandere*, to extend, and Paucton curiously enough derives it *à passis manibus*, from the length between the extended hands, instead of *à passis pedibus*. There is however reason to believe that the mille passus came into use from the practice of measuring distances in new countries from the number of paces marched by the soldiery, of which a rough reckoning was kept, but whether by actually counting the paces, or by the time of marching compared with the previously known number of paces in a given time, is not known. It is well known that with disciplined soldiers either method would give very good practical results. Vitruvius describes a machine to be fastened to the wheel of a chariot (an invention revived in our own day), by which its number of revolutions was registered; but this was probably a late invention.

The pace was not, as persons in general suppose, the step, or the distance from heel to heel when the feet are at their utmost ordinary extension; this, which the French metrologists call *pas simple*, was the *gradus* or *gressus*. The passus, or *pas double* of the same writers, was two gradus, or the distance from the point which the heel leaves to that on which it is set down. Assuming the Roman foot at 11·62 English inches, the pace, which was five feet, must have been 58·1 inches or 4·84 English feet.

Here we might have stopped, if it had not been necessary to explain something relative to what it pleased the writers of the middle ages to call the *geometrical* pace, composed of five geometrical feet. What they meant by this measure is not easily understood, except by the supposition (which some of their writings confirm) that they imagined a fixed and universal measure of length to exist in nature, and to have been actually obtained. At the beginning of the sixteenth century the Roman mile, at least the mile of 5000 feet or 1000 paces, was generally used by writers [MILE], and itinerary measures were more often written about than verified. The stadium, or eighth part of this mile, had also been introduced (into books) from the Greek system, and it was the common opinion, derived from Ptolemy, that the degree of latitude was exactly 500 stadia, or 62½ miles. This made the pace, or the 125th part of the stadium, stand forward as a proper universal measure, being the 62500th part of that which all believed the degree of latitude to be. But though this may be a probable origin of the geometrical pace, it is certain that writers did not adhere uniformly to it, so that the later metrologists have formed different notions of its length. We shall give the accounts of several modern writers.

Dr. Bernard makes the geometrical pace (which he also calls the land-surveyor's pace) to be five English feet. Greaves supposes that a pace of upwards of 69 inches was once in use in England. Ozanam makes the geometrical pace to be the same as the Roman pace. Eysenschmidt does not mention the measure at all. Paucton (who has a theory about the derivation of measures from parts of the human body) makes it only 4¼ Roman feet. Romé de L'Isle, who contends that Paucton has several times confounded the Greek Olympic foot with the Roman foot, makes it 4¼ Olympic feet, that is, 4¼ English feet very nearly. An older writer, Samson d'Abbeville, cited by Paucton, lays down the geometrical pace at 5 French feet, and nevertheless makes the Roman mile to contain a thousand such paces. The conclusion is, that the geometrical pace was an invention of the old writers, a needless addition to the confusion in which their accounts of antient measures were already enveloped.

There is a pace mentioned in ecclesiastical writers called *passus ecclesiasticus*, or *dexter* (see Ducange, at the word Dextri), which Dr. Bernard, without stating any authority, makes of the same length as the English yard.

PACHO'MIUS. [MONACHISM.]

PACHYCE'PHALA. [VIREONINÆ.]

PACHYCEPHALI'NÆ, Mr. Swainson's name for the Great-headed Chatterers, which form, according to his first arrangement in his *Classification of Birds*, the second subfamily of the *Ampelidæ*, or family of Chatterers, and are placed between *Leiotrichanæ* (Long-legged Chatterers) and *Bombycillinæ* (Swallow Chatterers), the other two subfamilies being the *Ampelinæ*, or True Chatterers, and the *Piprinæ*, or Manakin Chatterers. Of these subfamilies he considers *Leiotrichanæ*, *Pachycephalinæ*, and *Bombycillinæ* to be aberrant.

In the *Synopsis* in the same vol. (2), the family *Ampelidæ* are made to consist of the following subfamilies:—*Leiotrichanæ*, Silky Chatterers?; *Vireoinæ*, Greenlets and Thickheads; *Bombycillinæ*; *Ampelinæ*, Typical Chatterers; and *Piprinæ*, Manakins, subtypical.

In this last arrangement, *Pachycephala* is placed under the subfamily *Vireoinæ*. [VIREONINÆ.]

PACHYDE'RMATA (literally *Thick-Hides*; *Dickhäuter* of the Germans; *Pachydermes* of the French), the seventh order of mammiferous quadrupeds according to the system of Cuvier as set forth in his *Règne Animal*.

The *first* family of Pachyderms in this arrangement consists of those which have a proboscis and tusks, and which are named *Proboscideans*.

The *Proboscideans*, in the opinion of Cuvier, have many resemblances to certain *Rodents*: for instance, their great incisors (so to speak); their jaws, which are often formed of parallel laminæ; the form of many of their bones, &c. The whole of this family have five toes on each foot, completely formed in the skeleton, but so incrusted in the callous skin which surrounds the foot, that there is no appearance of them externally, except as they may be traced by the nails attached to the border of this species of shoe. The canines and incisors, strictly speaking, are wanting; but there are two tusks implanted in the incisive bones, which two tusks project from the mouth, and often grow to an enormous size. The proportions necessary for the alveoli or sockets of these tusks, render the upper jaw so high, and so much shorten the bones of the nose, that the nostrils are found in the skeleton towards the upper part of the face; but, in the living animal, they are prolonged into the well known proboscis or trunk, of which the reader will find a description under the article ELEPHANT. The parietes of the cranium contain large spaces for rendering l light; and the lower jaw has no incisors; as may n the same article. The intestines are voluminous, ich simple, and the cæcum enormous. The *mammæ*, two in number, are situated on the breast; and the young suck with the mouth, and not with the trunk, as some had erroneously supposed. The only living genus of Proboscideans is *Elephas*. [ELEPHANT.]

The other genus is extinct, and consists of the *Mastodons*. [MASTODON.]

The *second* family, *The Ordinary Pachyderms*, have either four, three, or two toes.

*

Those which have the toes equal are in some sort cloven-footed, and, in many respects, approximate the ruminants in the skeleton and in the complication of the stomach.

Living genera, *Hippopotamus* [see the article] and *Sus* (Linn.). [SUIDÆ.] Extinct genus, ANOPLOTHERIUM.

**

Those which are not cloven-footed form genera which very much resemble each other in the jaws, in having on each side seven upper molars with square crowns and various projecting lineaments, and seven lower ones with a double crescent on the crown, the last of all having a triple crescent; but their incisors are different.

Genera.—*Rhinoceros*; *Hyrax*; *Palæotherium*; *Lophiodon*; and *Tapir*. [See the articles.]

The third family consists of the *Solidungula*, which apparently have but one toe and a single hoof or shoe to each foot, but on each side of the metacarpus and the metatarsus are bony points or processes which represent two lateral toes.

Genus *Equus*, Linn. [HORSE.]

To these may be added the following extinct genera:—*Chalicotherium*, allied to the Tapirs [TAPIR]; *Chæropotamus*, belonging to the SUIDÆ; *Anthracotherium*, allied to *Chæropotamus* and the *Dichobunes* (*Palæotherium*); *Elasmotherium*, placed by Fischer between *Rhinoceros* and *Hyrax*; *Cœlodonta*, arranged by Meyer between *Rhinoceros* and *Dinotherium*; *Caïnotherium*, placed by Meyer between *Anoplotherium* and *Palæotherium*; and *Adapis* [ADAPIS]; and *Hippotherium*, an animal allied to the horse. [HIPPOTHERIUM.] *Dinotherium* is considered by Professor Kaup and others to be nearly allied to the *Tapirs*, in which case the extinct animal must doubtless find a place among the *Pachydermata*. [DINOTHERIUM; TAPIR.]

PACHY'MERES. [BYZANTINE HISTORIANS, p. 82.]

PACHYMY'A, Mr. James Sowerby's name for a genus of fossil conchifers thus characterised:—

Shell bivalved, transversely elongated, very thick, subbilobate, with the beaks near the anterior extremity. Ligament partly immersed, attached to prominent processes or fulcra. (J. S.)

To *Modiola* it bears much analogy in the position of the umbones or beaks, the elongated form of the valves, and the partial separation of the anterior portion into an imperfect lobe. It is distinguished from the thin shells allied to *Mytilus* by its comparatively short ligament fixed upon a strong prominent part of the shell within the edge. [MYTILIDÆ.] The genus is founded on a species, *Pachymya Gigas*, from the lowest part of the chalk formation near Lyme Regis. (*Min. Con.*)

PACHY'PTILA. [LARIDÆ, vol. xiii., p. 334; PETRELS.]

PACHYRYNCHUS. [PSARIANÆ.]

PACHY'STOMA, the Rev. Lansdown Guilding's name for a genus of his *Ampullariadæ*. The shell is described as having a thick marginated lip, frequently channelled, and a testaceous operculum. The genus is divided by Mr. Guilding into two sections: 1, consisting of the species which have a small umbilicus and a globose shell (*Ampullariæ globosa*, *corrugata*, and *puncticulata*, Sw.); 2, containing only one species (*Ampullaria crassa*, Sw.) with an evanescent umbilicus.

PACHY'TES. [DIANCHORA; SPONDYLUS.]

PACHYTHE'RIUM. M. Lund's name for an extinct genus of mammiferous quadrupeds approaching *Hoplophorus*, but of larger proportions than that genus. [MEGATHERIIDÆ, vol. xv., p. 73.]

PACIFIC OCEAN, THE, extends between America on the east, and Asia and Australia on the west. It received this name from Magalhaens, the first European who traversed it, and who, having experienced bad weather and heavy gales in the Strait of Magalhaens, sailed into the wide expanse of this ocean with a moderate south-east trade-wind, and enjoyed fair weather without interruption. He accordingly called it the Pacific. It is also called the South Sea, because vessels sailing from Europe can only enter it after a long southerly course. The name of South Sea has been limited in later times to the southern portion of the Pacific.

The Pacific is the greatest expanse of water on the globe, of which it covers more than one half of the surface. The area is roughly estimated at more than a hundred millions of square miles. Behring's Strait, which may be considered as its most northern boundary, lies between East Cape in Asia and Cape Prince of Wales, near 66° N. lat., and is less than 50 miles wide. From this point southward, the coasts of both continents, which enclose the Pacific, recede rapidly from one another, and at 55° 30′ N. lat., between the western point of the peninsula of Alashka and Cape Kronotskoi Noss in Kamtchatka, they are upwards of 1200 miles apart. Near the northern tropic, Cape S. Lucas in California is about 8000 miles from the coast of China east of Canton; and this may be considered as nearly the average width of the Pacific between the tropics. Near the southern tropic, Sandy Cape in Australia is about 8200 miles from the northern coast of Chile. Towards the southern extremity the Pacific is divided from the Atlantic by a line drawn from Cape Horn to the antarctic pole, and from the Indian Ocean by another line drawn from South-West Cape in Tasmania (Van Diemen's Land) to the same pole.

The Pacific does not, like the Atlantic and Indian Oceans, send off branches, which penetrate deeply into the adjacent continents; but extensive peninsulas project from the continents which border on it, and these, together with some adjacent rows of islands stretching far into the sea, separate considerable portions of it from the main body of the ocean. This is less the case on the American than on the Asiatic side. Only two peninsulas project from the American continent. The peninsula of California divides the Gulf of California [CALIFORNIA, GULF OF] and the peninsula of Alashka with the Aleutian Islands divides the Kamtchatka Sea, from the Pacific. The peninsula of Kamtchatka, which projects from the continent of Asia, divides the Kamtchatka Sea from the Sea of Okhotzk, which latter is separated from the open expanse of the Pacific by the Kurile Islands. The western shores of the Sea of Okhotzk are partly formed by the island or peninsula of Tarakai (or Saghalien), which projects at a very acute angle from the continent of Asia; and the islands of Jesso and Nipon and the peninsula of Corea enclose the Japan Sea on the north, east, and south. The Yellow Sea, or Hoang-hai, which is farther south, is less distinctly separated from the Pacific than the seas farther north; still the boundary-line between both seas is marked by a series of islands, which extend from the most southern extremity of the island of Kiusiu to the northern extremity of Formosa. This remarkable formation continues still farther south, and the Chinese Sea, which extends from the island of Formosa on the northern tropic to the equator, though it properly belongs to the Indian Ocean, must be considered as the last link in this chain of sea-basins. On the north the Chinese Sea is separated from the Pacific by a single row of islands, and farther south by a double and triple row. Thus we find, that though the continent of Asia forms the western boundary of the Pacific north of the equator, no part of it is immediately washed by that ocean, and its shores can only be reached by passing through one of these subordinate sea-basins.

This peculiarity of formation in the western parts of the Pacific appears to be mainly, if not exclusively, the effect of volcanic agency, when we consider that the peninsulas and islands, which separate the smaller basins from the main body of the sea, are either generally composed of volcanic rocks, or exhibit frequent and unequivocal traces of having been convulsed by subterraneous fire. Active volcanoes are still very numerous on them, and they form a continuous series which encircles the eastern coast of Asia like a girdle. The most northern of these active volcanoes which is known is that of Schiwelutschkaja in Kamtchatka (near 56° N. lat.), and it is followed by 13 or 15 others, all of which lie close to the shores of the Kamtchatka Sea on the eastern coast of the peninsula. The volcanic chain continues in the same direction, south-westward, nearly in a straight line to the island of Formosa on the tropic of Cancer. It forms the base of the Kurile Islands, on which at least ten active volcanoes are known to exist; appears in several places on the eastern and southern coasts of Jesso, and in the islands of Nipon and Kiusiu; and terminates in that direction with three if not more volcanoes on the island of Formosa. From the last-mentioned island the volcanic chain runs southward to the island of Luzon, where it declines a little to the east, traversing the peninsula of Camarinas (the southern part of Luzon), the other Philippine Islands and Mindanao, whence it passes to the north-eastern extremity of Celebes and the Moluccas. The last-mentioned islands exhibit everywhere traces of volcanic action, and contain several active volcanoes near 8° S. lat. The volcanic chain seems to terminate in that direction, or rather it turns westward nearly at a right angle, and continues through the Indian Ocean along the chain of the Sunda Islands. But near the equator, a branch of the chain runs off to the east along the northern coasts of Papua, or New Guinea, and continues through New Britain and the New Georgian Archipelago, where it begins to decline to the south. It is traced through the New Hebrides to the island of Tana. The most southern point of this lateral volcanic chain seems to be the small island called Matthew's Rock, south-south-east of Tana (22° 20′ S. lat. and 171° 15′ E. long.). In the northern island of New Zealand there are also unequivocal traces of volcanic agency. Thus we find that the western part of the Pacific is traversed by a volcanic chain, which extends from the neighbourhood of the northern polar circle nearly to the southern tropic.

Another series of volcanoes surrounds the Pacific on the east, but they are situated on the continent of America. These volcanoes do not constitute a continuous chain: they rather occur in extensive groups, at great distances from one another, but each group by itself may be considered as a chain. It is still doubtful whether active volcanoes exist on Tierra del Fuego. The British officers who surveyed these coasts some years ago do not appear to confirm the opinion of volcanoes existing on that group of islands. Near 50° S. lat. there are extensive fields of lava on the banks of the river Santa Cruz, but no active volcano has been observed in the Andes south of the volcano of S. Clemente, which is near 46° S. lat. With this summit begins the group of the Chilian volcanoes, which extends northward to 30° S. lat., where it terminates in the small volcano of Coquimbo. The number of active volcanoes in this group is about twenty; ten of them are between 40° and 35° S. lat. The most elevated is that of Aconcagua, near 32° 30′, which, according to the most recent information, attains an elevation of nearly 24,000 feet above the sea-level, and is the highest volcano on the globe. No active volcanoes occur in the Andes between 30° and 22° S. lat. Between 22° and 21° S. lat. is the Volcano de Atacama, the commencement of the Bolivian volcanoes, which extend northward nearly to 15° S. lat., and terminate with the extinct volcano of Chacani. The number of active volcanoes is five or six, and all of them are situated in the chain of the Andes west of the valley of Titicaca. Another break follows, which extends to near 2° S. lat., where the volcano of Sangay forms the commencement of the group of the equatorial volcanoes, which extend to about 5° N. lat., or to the Paramo de Ruiz, which was active in 1828. The number of active volcanoes, or of those whose eruptions are on record, is about ten; the most northern are in the chain of the Central Andes, between the valleys of the rivers Magdalena and Cauca. These are the three volcanic groups in the Andes of South America. On the Mexican Isthmus three groups of volcanoes occur between 9° 30′ and 19° 30′ N. lat. and 83° 30′ and 104° W. long. The most eastern are the volcanoes of Costa Rica. On the table-land of that name, between 9° 20′ and 10°, there are at least six active volcanoes close together. North of 11° N. lat. begins that chain of volcanoes which surrounds the Lake Nicaragua on the south, west, and north, and continues along the shores of the Pacific, and at no great distance from it, to the volcano of Soconusco (near 15° N. lat. and 94° W. long.). The number of active volcanoes may be about ten. The third group lies across the Isthmus near 19° N. lat. and contains six active volcanoes. On the peninsula of California, one of the three summits called the Virgins is an active volcano, but it appears to stand alone. Mount S. Helens, situated at some distance from the northern banks of the Columbia river, is also said to be an active volcano. The chain of the Aleutian Islands, which contains more than twenty active volcanoes, connects as it were the American volcanoes with those of Asia. The most western volcano, situated on the island of Little Sitkhin, is not much more than 500 miles from the series of volcanoes which line the eastern coast of Kamtchatka. The volcanoes of the Aleutian Islands also partake more of the nature of the Asiatic chains than of the American groups.

Though the Pacific covers more than one half of the surface of the globe, it receives the drainage of a comparatively small portion of the land. In South America, the watershed between the rivers which run into the Pacific and the Atlantic is hardly a few miles from the shores of the former towards the southern extremity of that continent. North of 40° S. lat. it is widest, the Andes being nearly 100 miles from the coast opposite the mouth of the Rio Biobio in Chile (37° S. lat.), but as they advance north, they approach nearer, and in all the remainder of South America the watershed is never more than 60 miles distant from the Pacific Ocean. Thus the Pacific receives hardly more than one twenty-fifth part of the drainage of South America. In the Mexican isthmus, as far west as the isthmus of Tehuantepec, the watershed continues at a short distance from the Pacific, never receding more than 40 miles, and frequently approaching it within less than 10 miles. West of the isthmus of Tehuantepec it gradually recedes farther, and at 20° N. lat. it is more than 300 miles from the shores of the Pacific; but farther north it again approaches to a distance varying between 120 and 200 miles. The countries of the Mexican isthmus, which send their drainage to the Pacific, probably constitute not more than one-eighth of that division of America. In North America (north of 32° N. lat.) the watershed lies much more towards the interior of the continent, being between 35° and 45° about 750 miles from the Pacific; but farther north it is only about 350 miles from it. The area of the countries of North America whose drainage runs to the Pacific probably does not exceed one-fifth of the whole surface. According to this rough estimate, the Pacific receives not quite one-tenth of the drainage of America.

In Asia, the watershed between the rivers which fall into the Arctic Ocean on one side and into the Pacific on the other is likewise at no great distance from the latter, north of the mouth of the river Amur, but the basin of this river extends above 1200 miles into the interior of Asia, and it is followed on the south by the basins of the rivers Hoang-ho and Yantse-kiang, which reach somewhat farther inland. The basins of these three rivers, added to those of a few others of inconsiderable extent, may comprehend nearly one-seventh part of the area of Asia, and so much of the drainage of that continent enters the Pacific. In Australia, as far as the country has been explored, the line which divides the waters which run into the Pacific from those which flow off in another direction is hardly anywhere more than 100 miles from the great ocean, and we may suppose that only one-tenth of the drainage of that continent is poured into that sea.

The shores of the continents which are washed by the Pacific are in general high and rocky. Along the coast of South America, south of the equator, they generally rise several hundred feet, except at the embouchures of the small rivers. No part of this coast presents an alluvium of any great extent. Along the Bay of Choco, which begins on the south near 3° N. lat., the shores are low but rocky; they rise a few feet above high water-mark, and the rocks are covered with an alluvial soil. The low shores continue through the Isthmus of Panama, but they rise again to a considerable height where the table-land of Veragua projects like a vast promontory into the ocean. This high coast reaches as far west as the vicinity of Realejo, where a sandy shore extends for several miles. High volcanic mountains surround the Bay of Conchagua, but west of it follows a low rocky coast covered with alluvium, which extends to the town of Tehuantepec. On the shores farther west the high land again comes close to the sea, forming a rocky coast of considerable elevation, which extends beyond 103° W. long. Then follows a low but probably rocky coast for nearly a hundred miles, which is succeeded by a more elevated coast extending to the port of San Blas. The eastern coasts of the Gulf of California are of moderate elevation and not rocky, and north of 28° N. lat. they become low and sandy; but the western shores of that gulf are rocky and elevated, except north of 30° N. lat., where a flat sandy beach extends to the mouth of the Rio Colorado. The western coasts of the peninsula of California rise with a steep rocky ascent to a considerable elevation, and the coasts preserve this character through the whole extent of North America, with the exception of the country surrounding the Bay of S. Francisco and a comparatively small tract of low country at the mouth of the Columbia river. North of the peninsula of Alashka, along the Kamtchatka Sea, the shores are of moderate elevation, and in general not rocky.

The coast of Asia along the western side of the Kamtchatka Sea is very rocky, and in many places of great elevation; this description applies likewise to the coasts of the Sea of Okhotzk and the Japanese Sea. The western coast of the peninsula of Corea is likewise high and rocky, but the western shores of the Yellow Sea, or Hoang-hai, are, with the exception of the peninsula of Shantong, very low, and consist partly of sand and partly of an alluvial earth; the latter principally occurs between the mouths of the Hoang-ho and Yantse-kiang. South of 30° N. lat. the coast of China is rocky, but in general of no great height. The eastern coast of Australia, as far as it is known, is chiefly rocky, but it does not attain a great elevation.

Turning from the countries which surround the Pacific to the interior of the ocean, we find that the eastern, northern, and southern portions are remarkably free from islands. In an extent of sea far exceeding the Atlantic in area, and bordering on the western shores of America, only a few isolated islands occur, and one considerable group, the Galapagos Islands. Between the coast of South America and Australia, south of 24° S. lat., only the large islands called New Zealand are situated; and in their vicinity there are a few small groups and islets: in the remainder of this vast extent of sea hardly four or five islands or diminutive groups are known to exist. But another portion of the ocean is abundantly diversified with islands of various dimensions. This portion of the sea lies between the two tropics, and extends from the western boundary of the Pacific eastward to 135° W. long., or over more than half the width of the ocean. To the north of the equator the islands and groups, though numerous, are much less so than to the south of the line. The islands of the Pacific are both low and elevated. The low islands are of very small extent, and are based on coral reefs, which encircle a small space of sea. This enclosed space resembles a lagoon, and these islands are often called Lagoon Islands. It was formerly supposed that these islands owed their origin entirely to the madrepores and other marine animals; but since it has been ascertained that these animals cannot exist in a depth of more than about ten fathoms, and as the islands rise with great steepness from a sea usually more than 300 fathoms deep, the question of the origin of these islands has engaged still more the attention of several naturalists. [Reefs.] The volcanic islands are of moderate extent, and generally rise to a great elevation in their centre. Besides the different groups which lie in a line from the eastern extremity of Papua to Matthew's Rock, and which have been already mentioned, several groups of volcanic islands are dispersed in the ocean. The groups of this description north of the equator are the Bonin Sima, Ladrone, and Sandwich Islands. The Galapagos are traversed by the equator. South of the equator are the volcanic groups of the Marquesas, Society, Navigator, and Friendly Islands, and the solitary Easter Island. Some of these volcanic islands are encircled by coral-reefs, as the Society, Navigator, and Friendly Islands: others have not such a circle of reefs, as the Sandwich, Ladrone, Bonin Sima, Galapagos, New Georgian Archipelago, and New Hebrides. The islands which do not belong to the volcanic or lagoon islands are few in number: the largest of them is New Caledonia, for the northern of the New Zealand islands is volcanic; as to the southern, we know nothing of it. A portion of the Pacific has a peculiar character. Flinders calls it the Corallian Sea, and determines its extent by assigning Papua and Luisiade as its northern boundary; whilst the north-eastern coast of Australia up to Sandy Point (21° 40′ S. lat.) encloses it on the west, and on the south a line drawn from Sandy Point to the Island of Pines near the southern coast of New Caledonia. On the east it seems to terminate at some distance from the New Hebrides. It extends more than 1000 miles in length, and about 600 in width. The whole space is covered with innumerable coral-reefs and banks, which have only a few feet of water on them, and are very dangerous to the navigator. This is probably both the largest and the most extraordinary reef in any part of the world. It is divided from the continent of Australia by a space of sea free from islands, in general from 20 to 30 miles and in some places even 60 and 70 miles coast. The area of the sea has generally a depth of between ten and twenty fathoms, but this depth increases towards the south to forty and even sixty fathoms.

The islands of the Pacific are inhabited by two, or, if the large island of Papua is included, by three races of men. *Papua* contains two different nations, the Papuas and the Haraforas or Alfoers [PAPUA]; and it is not improbable that these two races are also to be met with on the larger islands east of Papua, as in New Britain and New Ireland. The islands forming the volcanic chain which stretches from Papua eastward and afterwards inclines to the south-east and south, together with the large island of New Caledonia, are inhabited by a race resembling the negroes, and hence they have obtained the name of Austral negroes. It is generally supposed that the black inhabitants of these islands and the natives of the continent of Australia are of the same origin; but this point has not been well established. The Papuas, as the inhabitants of the islands are usually called, certainly resemble, in their hair, colour, and some other features, the natives of Australia; but the whole frame of their bodies is different, and, as it appears, the facial line also. They are still more distinguished by their mental qualities and the higher state of civilization which they have attained. Whilst the Australians have remained in a state little above that of animals, living without dwellings and covering, and using for food the crude productions of nature, shell-fish, and the fruits of wild bushes and trees, the Papuas build large houses, which are well arranged, cover a part of their body with stuffs made from the bark of trees, and cultivate several plants and trees for food. This superiority of the Papuas over the Australians is not less evident in the skill with which they make their arms, and especially in the construction of their boats, which are frequently fifty and sixty feet long, and so well built that voyages of a hundred miles are made in them. The Australians, we believe, have never ventured to leave their shores, and never built any boats. The Papuas also rear several domestic animals, as hogs, dogs, and fowls. The Australians never seem to have made any attempt of the kind. The former live in regular political societies, whilst the Australians do not seem to know any other bond than that of the union of families. Our knowledge of the languages spoken by the different societies of the Papuas is far from being sufficient to enable us to determine whether there is such a similarity between them as to lead to the inference of their being derived from one common stock.

All the islands east and north of the volcanic chain, as well as the large islands, including New Zealand, are inhabited by a race which, in their physical character and in the different dialects spoken by them, so strongly resemble the Malays, or inhabitants of the Indian Archipelago, that there can be no doubt of their common origin. In that part of the ocean where most of these islands are scattered, the direction of the winds and currents during the whole year is from the east to the west, and accordingly it seems difficult to understand how this race has spread from the west to the east against both winds and currents; and it may be supposed that the migration has taken place in the contrary direction. But the migration from the west to east is proved by the fact that, in proceeding in that direction, the number of species of cultivated plants and domestic animals is decreasing, which shows that those who migrated in that direction were not always able to take with them to their new abode all the plants and animals belonging to the place which they left. It is also to be observed that all the plants and animals in these islands are natives of the Indian Archipelago, and hardly any one of them was found in South America before the arrival of the Europeans. To show the possibility of the migration in an eastern direction, Capt. Fitzroy observes that we are too little acquainted with the direction of the currents between 10° and 20° S. lat. to say more than that in settled weather and a steady trade-wind (south-easterly), the surface-waters in general move westward from five to twenty miles a day; and that in the rainy season (from October to March), when westerly winds, squalls, and rains are frequent, the currents vary most, and occasionally set eastward at the rate of from half a mile to two miles an hour. He adds that there are numerous instances on record of canoes being drifted several hundred miles out of their course by currents and westerly winds, and that this fact may explain how the remote islands, as for instance Easter Island, may have been first peopled from the west.

Before the beginning of the present century only a few vessels visited the Pacific, and the number has only increased considerably since the independence of South America was established in 1820; our knowledge of those points which more immediately affect the navigation, the winds and currents, is therefore far from being so complete as that which we possess of the Atlantic in these respects. Still enough has been ascertained to make us acquainted with the principal facts.

The north-east trade-wind seems to be more regular than in the Atlantic, and its northern boundary does not vary so much. It is true that Cook, in passing from the Sandwich Islands to the coast of the North American continent, found the trade-wind as far north as 30° in the month of February; but as other navigators have not met it higher than 26° N. lat., it is probable that the wind which retarded the progress of Cook was a north-eastern wind of a changeable nature. Many later navigators met the trade-wind when the sun was in the southern hemisphere between 19° and 20° N. lat. From these facts it appears that in summer this wind extends to 26° N. lat., and in winter only to 20° N. lat.; and that the mean boundary may be placed at 23° N. lat., from which it does not recede more than three degrees. As to the southern boundary of this wind, our information is very scanty, a circumstance which seems to be due to the fact that navigators are seldom obliged to pass through the region of calms which intervenes between the two trade-winds, and that they avoid a course which is always attended with great delay. In the Atlantic the case is different, as every vessel sailing to South America or the Cape of Good Hope is obliged to pass the region of calms. It is therefore merely a conjecture when it is stated that the southern boundary of the north-east trade-wind varies between 3° and 7° N. lat., and that the mean boundary is between 4° and 5° N. lat.

Respecting the south-eastern trade-wind, Capt. B. Hall states that near the continent of South America, when the sun is in the southern hemisphere, the trade-wind extends to between 30° and 31° S. lat., and that in the opposite season it is met with four or five degrees farther north, near 25° S. lat. But Cook found that in the interior of the Pacific this trade-wind does not extend south of 20° S. lat., at least not when the sun is in the northern hemisphere. When the sun is in the opposite hemisphere, the regular trade-wind seems to advance to 25° or 26° S. lat. But according to several statements, it would appear that this wind is by no means so regular along its southern border as in the Atlantic, and that it is frequently interrupted by winds from the west and south-west.

In the Pacific, as in the Atlantic, the south-east trade-wind extends some degrees north of the equator when the sun is in the northern hemisphere. In the beginning of July, Capt. B. Hall met with it in 3° 30′ N. lat.; and this is the season in which it may be considered as advancing farthest to the north. The last-mentioned navigator observes that towards their northern boundary these winds blow from the south, but farther south gradually draw more to the east, and at their southern limit are quite easterly. In the opposite season, the south-east trade-wind seems to recede from one to two degrees south of the equator, as is the case in the Atlantic Ocean.

The want of exact information respecting the southern boundary of the north-east trade-wind renders it impossible to compare the extent of the Region of Calms in the Pacific with that in the Atlantic. It is certain that in the Pacific the central line of this region is north of the equator, but probably nearer to the line than in the Atlantic; perhaps between 2° and 3° N. lat. In passing this region the navigator meets with calms, interrupted by short squalls and accompanied by a little rain.

The south-east trade-wind is not met with near the coasts of South America, but only at a distance of from 300 to 400 miles. In the intervening space the wind always blows in the direction of the Andes from the south, changing during the day a few points to the west, and in the night freshening off from the land. These winds are always very light, and sometimes interrupted by calms. North of Guayaquil the winds always blow from the south-south-east, and are steady. The north-east trade-wind does not approach the coasts of the Mexican isthmus nearer than the south-east shore of South America. It is only met with at a distance of above 700 miles from the land. In the tract of sea lying between their eastern limit and the coast different winds prevail in the different seasons. From June to November, both included, the prevailing wind is from the north-west and west; it is very boisterous, and frequently comes in heavy gales, and tornados or furious squalls, which are accompanied by deluges of rain and most dangerous thunderstorms; they are sometimes interrupted by calms. These winds set in earlier at the eastern parts of the isthmus than in the western. At Panama they are expected in March, and at S. Blas in the middle of June. During this season the navigation along this coast is very dangerous; there are also few good harbours, and even most of them are abandoned by the inhabitants on account of their unhealthiness. In the opposite season, from December to May included, the prevalent winds between Panama and Cape Blanco de Nicoya are north-west and northerly, and they are pretty steady. From Cape Blanco de Nicoya to some distance east of Acapulco the winds blow from east and north-east, generally with moderate strength, but they are sometimes interrupted by hard gales from the north-east, which are called Papayagos, and are experienced between Cape Blanco (9° 30′ lat.) and Cape S. Catherine. They last for several days, with a clear sky overhead and a dense red haze near the horizon. Other gales of a similar description sometimes occur in this season east of Acapulco, opposite the isthmus of Tehuantepec, whence they are called Tehuantepec gales. They blow from the north. West of Acapulco, and from 60 to 100 miles from the land, the winds are variable, but the prevailing winds blow between south-south-east, and west-south-west. Nearer the coast, land and sea breezes are met with, blowing from the north-west during the day, and from north-east at night. They are experienced also east of Acapulco to a distance of about one hundred miles.

It seems that the trade-winds cease at a considerable distance from the eastern coasts of Asia, and that in the tract of sea bordering on these coasts they are replaced by variable winds blowing generally from north-west and south-west, and also from south-east. But our information on this point is far too scanty to entitle us to speak even with a moderate degree of certainty. We are likewise entirely ignorant of the limits where these winds cease opposite the eastern coasts of Australia. They seem to blow as far west as the Corallian Sea, a portion of the ocean which is very seldom visited by vessels. Along the coasts of Australia the winds are very variable.

In the region of the *variable* winds, south of the trade-winds, the weather and the turn and succession of the winds are, according to Capt. Fitzroy, remarkably uniform. According to his account, north-westerly winds prevail, bringing clouds and rain in abundance. South-westerly succeed them, and partially clear the sky with their fury; then the wind moderates and blows from the south-east quarter, where, after a short interval of fine weather, it dies away. Light airs spring up from the north-east, freshening as they wear round to north, and augment the store of moisture which they always bring. From the north they soon shift to the usual quarter, north-west, and between that point and the south-west they shift back sometimes for weeks before they take another turn round. It never blows hard from east, rarely with any strength from north-east, but occasional gales may be expected in winter (between June and August) from south-east. Heavy tempests blow from west-north-west to south-west. In the region of the variable winds north of the trade-winds, the winds usually blow from the north-west and west, and frequently in gales. When not strong, they are accompanied with heavy fogs. It seems however that in the subordinate basins along the coasts of Asia, the Yellow, Japanese, and Okhotzk Seas, easterly winds are prevalent. In the last-mentioned basin at least, east and south-east winds are constant in summer, and in winter are more frequent than other winds.

Respecting the *Currents* of the Pacific our information is still more scanty and doubtful. The facts which have been recorded, though numerous, are few when the immensity of the subject and the difficulties which arise from its peculiar nature are considered. These facts are also mostly disjoined, so that in many instances they cannot be connected without conjecture and hypothesis. Consequently little can be said on this subject.

It is certain that near the southern polar circle a con[illegible] portion of the surface of the ocean is in motion [illegible] north. This portion is situated between 140° and 200° W. long. North of 60° S. lat. it gradually turns eastward, and between 45° and 35° S. lat. it sets towards the coast of South America, where it seems to divide in the tract of sea west of the island of Mocha (38° S. lat.) and Cape Rumena (37°). The more narrow branch runs off southward towards Tierra del Fuego. It is frequently strong north of 40° S. lat., but feeble farther south, except during and before strong or lasting southerly winds. It continues along the southern coasts of Tierra del Fuego to Cape Horn westward, and is found in this part to run with an average rate of a mile an hour. Its strength is greater during westerly winds, and sometimes during easterly winds is nearly imperceptible. As the current sets rather from the land, it diminishes the dangers which attend the navigation along such a rocky coast. Opposite the island of Mocha and Cape Rumena, and some distance west of them, the current, according to Capt. Fitzroy, usually runs to the north-west at the rate of from half a mile to a mile and a half an hour. But the current is not wide; and from 20 to 30 miles from the land, it is hardly perceptible. This however seems to be the beginning of the Peruvian current, which runs hence northward along the western coast of America as far north as Punta de Pariña (near 5° S. lat.). The current extends about 100 miles from the coast, and is of moderate velocity, generally not exceeding a mile an hour. It is however remarkable on account of the cold water which it carries from the south to the north. The difference of the temperature of the water within the current and that of the surface of the ocean without the current is considerable. At Callao the former indicates 62° Fahr., whilst in the same latitude, but about 300 miles from the coast, the temperature of the sea is between 77° and 79°. From the Punta de Pariña the current recedes from the coast, running off in a north-western direction to the islands of Galapagos, enlarging in width, but increasing in velocity. Near these islands Capt. Fitzroy found the current setting north-west, and running between two and five miles an hour. Though the current has now reached the equator, its temperature has not increased. Along the southern shores of Albemarle Island, one of the Galapagos, the thermometer immersed in the sea only indicates 60°, while on the northern shores it stands at 80°. The high temperature of the water on the north side seems to be the common temperature of the sea near the equator, but Capt. Fitzroy ascribes it to a warmer body of water issuing from the Bay of Panama, which he considers as a sort of Gulf-stream. From the Galapagos the current runs westward towards the centre of the ocean, and it increases considerably in width, the northern border advancing some degrees north of the equator, while the southern runs south-west, and passes 10° S. lat. But its velocity decreases gradually as it proceeds westward, whilst its temperature increases. About the meridian of 103° W. lat., Capt. Beechey found it still running 28 miles a day. A difference between the water of the current and that of the sea without it is still sensible as far west as 150° and 160° W. long., where the former is about 77° and the latter is increased to 85°. Before the current reaches 180° W. long. it is lost in the drift-current, which appears in the ocean as far as the trade-winds prevail, and the difference of the temperature is no longer perceptible. Along the northern border of the Peruvian current, between 120° and 150° W. long. and between 5° and 10° N. lat., a current has been observed, which sets in an opposite direction eastward, but the facts are still too few to enable us to determine whether it is only the counter-current of the Peruvian current or a separate current.

The body of warm water which, according to Capt. Fitzroy, joins the Peruvian current near the Galapagos Islands, and which issues from the Bay of Panama, has been already mentioned. This body of water may be connected with the Mexican current, which runs along the coast of Central America and Mexico between 85° and 105° W. long. It is perceptible as far as 100 miles from the coast, but the current alternates. From December to April it runs eastward, and from May to December westward. The velocity is moderate, never exceeding one mile and a half in an hour. The temperature of the water has not been determined, but it is supposed that it is warmer than that of the sea farther west. Capt. Beechey found a girdle of warm water between the equator and 14° 22′ N. lat., in 102° W. long. This is the last permanent current which requires to be mentioned in the eastern portion of the Pacific south of the northern tropic.

The drift-current of the trade-winds seems to be much less rapid than in the Atlantic. According to Capt. Beechey it does not exceed five miles per day. But where this drift-current approaches the western borders of the Pacific, especially the islands which lie between the north-eastern part of Australia and the south-eastern coasts of China, and which occupy a space of 35 degrees of latitude, it begins to divide into several currents of greater velocity, among which three are noticed particularly. The most southern seems to separate from the drift-current between the Friendly and Fidjee or Viti Islands, between 170° and 180° W. long., and to run to the New Hebrides and New Caledonia, but it appears to be lost before it reaches the Corallian Sea. Little is known of it. The second lies much farther north, between the equator and 8° or 9° N. lat., and runs along the northern coast of Papua, or rather at some distance from it. It begins near 140° E. long., and terminates in the straits which divide the western extremity of Papua from Gilolo. This current is influenced by the monsoons prevalent in that sea, so that during the south-west monsoon it sets eastward, and westward during the north-east monsoon. It frequently runs with great velocity, especially in the western portion. The third current, which branches off from the drift-current of the trade-winds, is observed along the northern border of this region. It sets westward with moderate strength, until it is lost in the sea between the Philippine Islands and Japan opposite the island of Formosa. Its width is not well ascertained.

South of the trade-winds and without their reach, a current is observed along the eastern coast of Australia south of Sandy Point. It has been asserted that this current always sets southward; but the more accurate investigation of Jeffreys shows, that from 28° S. lat. to the southern extremity of Tasmania, or Van Diemen's Land, the current during the summer, or from August or September to April or May, sets along the coast, and seaward to a distance of 15 or 18 miles, to the west of south, with a force of about one mile and a quarter in an hour; but at the distance of between 18 and 50 miles, to the east of north, running about three-quarters of a mile in an hour. In winter, these currents run in the opposite direction. This is partly confirmed by Captain Fitzroy, who says, that in the passage from New Zealand to Sidney he found alternately northerly and south-easterly currents, and that while the stream set from the north the temperature of the water was 72°, but when the current ran from the south only 67°.

North of the drift of the trade-winds, a constant current is found to set along the southern coast of Japan eastward, and to decline at about 145° E. long. to the north. It runs with considerable strength, and is perceptible at a great distance from the shores. Whether this current, like the Gulf-stream in the Atlantic, traverses the whole breadth of the Pacific, is not known; but a strong current setting in an easterly direction in this portion of the Pacific was experienced by Kotzebue, who found that near 40° N. lat. he had been set five degrees of longitude in 15 days, or about 15 miles a day; and a current of similar strength seems to run along the northern coast of America from 55° to 30° N. lat., but along these shores it sets south-east.

It does not appear whether the last-mentioned current is connected with the current in Behring's Strait, but it is certain that a strong current sets through this strait northward, or rather north-north-east. It is strongest on the Asiatic shore, where it runs from two to three miles an hour, but on the American shore only one mile and a half on an average. This current prevents the masses of ice which surround the arctic pole from advancing southward and spreading into the Kamtchatka Sea: it presses them together between the northern shores of America and Asia, where they constitute an impenetrable barrier, and render abortive the attempts of the most skilful and boldest navigators to advance nearer to the pole.

The tracks kept by vessels in navigating a sea are of course determined by the knowledge which the seaman possesses of the direction of the winds and currents. We shall mention the most important of these tracks. Vessels bound from Valparaiso or any other port of Chile, for Callao or Guayaquil, keep along the shore of South America at no great distance from the land, as in these parts both winds and currents are always in their favour, both being to the north. But in the voyage from Callao and Guayaquil both the wind and current are contrary, and accordingly vessels after leaving these ports sail south-west or west-south-west, until, having obtained a distance of 300 or 400 miles from the land, they meet the trade-wind, by means of which they make southing until they get out of the trade-wind into the region of the variable winds, where they direct their course to the place for which they are bound. In winter therefore they sail southward to 30° or 31° S. lat., before they endeavour to make some port, and in summer only to 25° S. lat.

In sailing from the ports of Peru and Chile to those of Acapulco, S. Blas, and Guaymas, three different tracks are followed. From December to May, their course from Peru to Mexico generally lies near the continent and within the Mexican current, as this current sets westward during this season, and the winds along this coast are partly favourable. But in returning in the same season from Acapulco to Guayaquil or Callao, the vessels get out of the current by a southerly course and then sail parallel to the continent, but about 300 miles from it, until they come opposite the Bay of Panama, when they shape their course to the place of destination. This track is called by the seamen of the adjacent countries, *navigacion por el meridiano*. But from May to November the track of the sea along this coast is subject to hard gales and squalls and extremely bad weather, and the navigation is accordingly unsafe, and is avoided. During this season the vessels draw off from the shores to the distance of a thousand miles and more, and then, by means of the trade-winds and the prevalent currents, they try to make southing or northing, according to the direction of their voyage. This tract is called *navigacion por altura*. This course is chiefly kept by vessels sailing between the ports of Mexico and Chile. Those which sail from Mexico to Guayaquil or Callao keep closer to the shores of Central America, and when they have passed the Bay of Panama, they shape their course to Guayaquil and Lima.

The track most frequented in traversing the whole expanse of the Pacific from east to west and west to east, lies in the eastern portion of the ocean, in a south-eastern and north-western direction. Vessels leaving the ports of Mexico sail westward, but those from South America sail north-west, until they reach 20° N. lat., about ten degrees east of the Sandwich Islands. These islands, lying nearly in the middle of the track between South America and the Chinese Sea, are commonly resorted to for refreshments. From the Sandwich Islands the direction of the track is nearly west, between 15° and 20° N. lat., and the Chinese Sea is entered by the straits between the island of Luzon and that of Formosa. This is the northern track across the Pacific, and it is considered the shorter, because the voyage is thus made in less time than by the southern track; the latter is really somewhat shorter, but as it lies through a sea beset with numerous low islands and reefs, the vessels are exposed to much more danger, and the precautions necessary to avoid them cause a delay which renders the voyages longer than by the northern track. This southern great thoroughfare across the Pacific runs between the Paumoto Islands on the south and the Marquesas on the north, and lies mostly in the southern hemisphere, cutting the equator near 165° E. long., whence it continues north-west and joins the northern track between Luzon and Japan. These two lines are followed by vessels from the coast of South America; the northern also is followed by those from Central America and Mexico bound for China and the East Indies. But in these parts of the ocean the winds and currents being to the west, vessels which follow them on their return to America would meet with great delays, and therefore the tracks which they follow in sailing eastward lie beyond the limit of the trade-winds and their drift-current, either north of 30° N. lat. or south of 30° S. lat. Vessels sailing from the Chinese Sea to the ports of Mexico or the western coast of North America, and having passed either to the south or north of the island of Formosa, and usually on the north during the south-west monsoon, soon reach by a north-eastern course the sea where the trade-winds and their currents are not felt. In keeping north of 30° N. lat. they traverse a sea free from islands and dangers, and make the coast of the peninsula of California south of 36°, whence they direct their course to the port for which they are bound. Vessels sailing from Sidney to South America pass between New Zealand on the south and Norfolk Island on the north, and keep an easterly course until they enter the sea near the coast of South America, where the trade-winds do not blow and the current sets north. On arriving there, they reach their destination by the tracks already mentioned.

With respect to vessels sailing from Sidney to the Indian Archipelago, they may make the Western Passage, which lies through Bass's Strait and round Australia through the Indian Sea, or they may make the Eastern Passage. The Inner Eastern Passage lies along the north-eastern coast of Australia and leads through Torres Strait. This passage is far the shortest, but it is rarely used by vessels sailing to India, on account of the numerous dangers to be encountered in the long and narrow strait between the rocky coasts of Australia and the numerous reefs of the Corallian Sea, though this part of the sea has been surveyed and laid down with great accuracy by Flinders. In the only season in which it could be navigated with advantage, that is during the north-west monsoon, the dangers are increased by frequent fogs of long continuance and by variable winds. The Outer Eastern Passage however is frequently used by vessels sailing from Sidney to India. In sailing along this track, a vessel after leaving Sidney runs eastward till it has passed to the east of the Corallian Sea; it then turns northward, leaving New Caledonia and the New Hebrides on the east, until it gets near the New Georgian Archipelago. It then sails along the southern borders of this archipelago, but at some distance from it, and passes through St. George's Channel between New Britain and New Ireland, whence it runs along the northern coasts of Papua and enters the Indian Sea either by Gallowa Strait between Papua and the small island of Sallawatty, or by Pitt's Strait between Sallawatty and Battante, another small island. Though this track is frequently taken by vessels bound from Sidney to the Indian Archipelago or Bengal, it is not used by vessels sailing in an opposite direction, which always prefer the Western Passage round Australia.

It has been already observed, that the current which sets northward through Behring's Strait prevents the ice of the Arctic Polar Sea from passing southward into the Kamtchatka Sea. It may be added, that the floating masses of ice of the Antarctic Polar Sea are frequently met with towards the American coast, but beyond the southerly current, between 50° and 60°, and between 140° and 200° W. long., and even north of 50°. Farther west, in the sea south of Australia, it is supposed that ice never passes beyond 60° S. lat.

PA'CIO, GIULIO, born in 1550, at Vicenza, in the Venetian state, learned Latin, Greek, and Hebrew at an early age, and became well acquainted with every branch of classical learning. Being accused before the ecclesiastical authorities of reading books forbidden by the church of Rome, he became alarmed, and escaped to Switzerland, where he earned his livelihood as a teacher. He was afterwards appointed professor of philosophy at Heidelberg, where he assumed the name of 'Pacius à Beriga,' from a country-house belonging to his family near Vicenza. He travelled through Germany and Hungary, and after some years he was invited by the duke of Bouillon to his newly established university of Sédan, where he taught philosophy with great success; but the civil wars raging in that part of the country, he removed to Nismes, and thence to Montpellier, where he was made professor of law in that university about the year 1600. The afterwards celebrated Peiresc was one of his disciples. Henri IV. bestowed on Pacius the honorary rank of king's counsellor. Pacius had long professed the reformed religion, and Peiresc earnestly but unsuccessfully attempted to induce him to settle near him at Aix, and to return to Catholicism. From Montpellier, Pacius removed to the university of Valence in Dauphiné, where his reputation as a jurist increased and spread throughout Europe. He was offered chairs at Leyden, Pisa, and Padua. He chose the last university, where he was received with great honours, and the Venetian senate made him a knight of St. Mark. After some time however he returned to his family, which he had left at Valence, where he died in 1635. A friend wrote the following distich for his monument:—

Itala dat cunas tellus, Germanica famam,
Gallica jus civis: dic mihi quæ patria?

Pacio wrote many treatises and commentaries on the Roman law; among others: 1, 'De Juris Methodo Libri Duo.' 2, 'Juris Civilis Romani Initia et Progressus,' consisting of a Commentary on the twelve Tables, of Notes on Fragments of Ulpian and Gaius, on Pomponius 'De Origine Juris,' and upon the last two titles of the Pandects. 3, 'Picturæ duæ de Gradibus secundum Jus Civile et Canonicum.' 4, 'De Contractibus.' 5, 'De Pactis et Transactionibus.' 6, 'In Decretales Libri V.' 7, 'Consuetudines Feudorum.' Pacius edited also the following works:—8, 'Corpus Juris Civilis cum Notis et Legum Argumentis,' fol., Geneva, 1580. 9, 'Justiniani Imperatoris Institutionum Libri IV.' 10, 'Sapientissimi Curopalatæ de Officialibus Palatii Constantinopolitani et Officiis Magnæ Ecclesiæ Libellus,' Greek and Latin, Heidelberg, 1589. He also published several editions of the 'Organon' of Aristotle, of which he made a new Latin translation. He also edited the works of Aristotle, in 2 vols. 8vo., 1597. His other works on various subjects are: 11, 'In Porphyrii Isagogen et Aristotelis Organum Commentarius analyticus,' 4to., Frankfort, 1597. 12, 'De Dominio Maris Hadriatici inter Serenissimum Regem Hispaniarum ob Regnum Neapolitanum et Serenissimam Rempublicam Venetam,' Lyons, 1619. In this curious work he defends with great skill the dominion asserted by the Venetian republic over the Adriatic Sea as far as Cape Leuca, on the several grounds of old prescription, of having its territories round the greater part of that gulf, on the obligation of keeping it free from pirates, and maintaining the only naval armament on its coasts. The work is interesting, as affecting other similar questions of 'mare clausum' and the rights of dominion claimed by other powers over the narrow seas near their coasts. 13, 'Doctrina Peripatetica.' 14, Lastly, after Pacio's death, was published at Amsterdam, in 1643, 'Posthumus Pacionus, seu Definitiones Juris utriusque.'

(Lorenzo Crasso, *Elogi di Uomini Letterati*; Thomasini, *Elogia Doctorum*; Gassendi, *Vita Peirescii.*)

PA'CLITES, De Montfort's name for a genus of *Belemnites*, composed of those species which are described as being curved towards the extremity, with a pore at the apex, and a straight elongated aperture. *Belemnites unguiatus* of De Blainville is an example.

PACTO'LIANS, the name by which M. Milne Edwards designates a tribe of the Apterurous family of the Anomurous section of crustaceans. The other tribes belonging to this family are the *Dromians*, the *Homolians*, the *Raninians*, the *Porcellanians*, the *Hippians*, and the *Pagurians*. (See these different tribes under the respective family titles or leading generic names, such as HIPPA; HIPPA TRIBE.) The *Pactolians* are placed by the author above named between the *Homolians* and the *Raninians*.

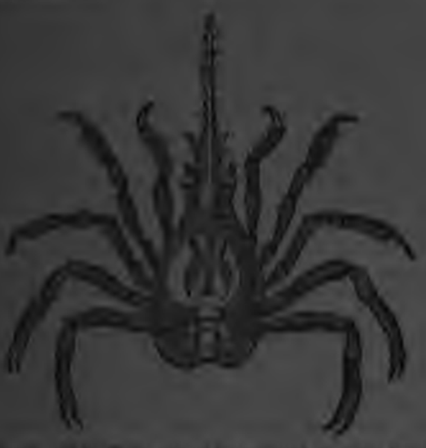
But it is not without some uncertainty that M. Milne Edwards gives such a position to the singular crustacean described by Dr. Leach under the name of *Pactolus*. In the conformation of the *carapace*, the *mouth*, and the *abdomen*, indeed, it resembles some of the *Oxyrhynchs*, but in the structure of its feet there are anomalies which distinguish it from other Decapods. The anterior feet are fingerless, whilst the two last pairs are terminated by a didactylous claw. Upon this form the family entirely depends, for no other genus, we believe we might add species, is known.

Pactolus.

Generic Character.—First joint of the *external antennæ* long and cylindrical. *Feet* moderately long and rather stout, the two anterior shorter than the others, not terminated by a *manus* or pincers, but only provided with a simple hooked nail; the second pair terminated in the same way; the third pair unknown; fourth and fifth pair didactylous. *Carapace* triangular, elongated, rather convex on each side behind, not thorny above, and terminated anteriorly by a very long, sharp, delicate and entire rostrum, similar to that of the *Leptopodiæ*. [MACROPODIANS, vol. XIV., p. 233.] *Abdomen* of the female composed of five joints, the first narrow, the three following transverse and linear, and the fifth very large and nearly rounded. *Eyes* very large, situ-

and behind the antennæ, always projecting from them; a single spine behind each orbit.

Example, *Pactolus Boscii*. Length eight lines, nearly two of which belong to the rostrum, which is furnished with small spines directed obliquely on the sides; carapace smooth, brownish; feet variegated with reddish and whitish. Country unknown.



Pactolus Boscii. [illegible]

PACTOLUS. [Lydia.]

PACU'VIUS, MARCUS, a native of Brundusium, a Latin dramatic poet, and the nephew of Ennius, also distinguished himself as a painter. He was born about 219 B.C. Pliny (*Hist. Nat.*, xxxv. 4, 7) mentions some works executed by him in the temple of Hercules, in the Forum Boarium at Rome, which apparently did him considerable credit; he remarks at the same time that he was the last who painted with *honest hands* ('honestis manibus'), with the exception perhaps of Turpilius Labeo of Verona, a Roman knight of his own time.

Some fragments of the tragedies of Pacuvius are still extant, and according to Quintilian (*Inst. Or.*, x. 1) they were not without their merits. He died at Tarentum in the 90th year of his age. He wrote a simple epitaph upon himself, which has been preserved by Aulus Gellius (i. 24): 'Adolescens, tametsi properas, te hoc saxum rogat, uti ad se aspicias, deinde quod scriptum est legas. Hic sunt poetæ Pacuvii Marci sita ossa. Hoc volebam nescius ne esses: vale.' The fragments of Pacuvius were collected by Henry Stephens, Paris, 1564, 8vo., and have since been printed in several editions of the 'Corpus Poetarum Latinorum.' Cicero, in his treatise 'On Friendship' (c. 7), introduces Lælius as speaking in terms of commendation of the 'Orestes' of his friend Pacuvius. Pacuvius was fifty years older than Attius, who exhibited a play in his thirtieth year, at the same time that Pacuvius, then in his eightieth year, exhibited one. (*Cic., Brut.*, c. 64.)

PADANG. [Sumatra.]

PADDINGTON. [London.]

PADDY BIRD. [Rice Bird.]

PADERBORN, formerly a bishopric of the German empire, in the *circle* of Westphalia, was assigned to Prussia in 1802; it is now divided among the three governments which form the Prussian province of Westphalia; the portion still called Paderborn is a circle of the government of Minden. It is bounded by some offsets of the Egge Mountains, but on the whole it is level, and has extensive heaths and marshes. The soil is fertile, but does not produce sufficient corn for the home consumption. Much hemp is grown; the forests are considerable; the inhabitants breed great numbers of sheep and swine; the mineral products are coals, iron, and salt.

PADERBORN, the capital of the circle, in 51° 43′ N. lat. and 8° 45′ E. long., is situated on the river Pader, from which it has its name, signifying 'the source of the Pader.' This river is formed by five springs that rise under the cathedral and the adjacent houses. It is surrounded with walls and has five gates. The houses of Paderborn are tolerably well built, but the streets are narrow and dark. It is said to have been for a time the residence of Charlemagne, who founded the bishopric. The building of the cathedral was begun in the year 777; it was destroyed by fire in 1000. A new cathedral was completed in 1015, but the chapel of St. Bartholomew is the only part of it that remains. The present cathedral was built in the twelfth and fourteenth centuries, and underwent many changes in the fifteenth, sixteenth, and seventeenth centuries. The steeple was destroyed by lightning in 1615. The cathedral contains the remains of St. Liborius (which were brought from France in 836) in a coffin of silver gilt. It formerly possessed, besides other treasures, the golden images of the twelve apostles, which Duke Christian of Brunswick, who took the city in 1622, carried away with him, as well as the silver coffin, which at that time contained the body of the saint, and which he coined into dollars, with the legend, 'The friend of God and the enemy of the priests.' There are three other Roman Catholic churches and one Protestant church, a seminary for priests, a Catholic gymnasium, a Jewish school, and numerous useful and charitable institutions. It is still the see of a bishop and chapter. The university, founded in 1622, was abolished in 1819, and the funds applied to the gymnasia at Paderborn and Münster.

Paderborn was one of the Hanse towns, and a free imperial city, but became subject to the bishop and chapter, and the capital of the bishopric. The inhabitants, 8000 in number, have no manufactures of importance, but extensive breweries and distilleries, and a considerable inland trade.

PADILLA, JUAN LOPEZ DE, the leader of a popular insurrection in Castile against the ministers of Charles V., known as *La Guerra de las Comunidades*, was the son of Pedro Lopez, a nobleman who held the high office of *Adelantado Mayor* of that kingdom. After the death of Ferdinand V. (1516), the crown of Aragon and Castile, together with the extensive possessions dependent on them in Europe, as well as in Africa and America, devolved upon his grandson Charles, then in his sixteenth year. [Charles V.] The young prince appointed Adrian of Utrecht to administer the kingdom in his absence, but such was the aversion of the Spaniards to the government of a stranger, that Adrian's claim would at once have been rejected, had not the celebrated Cardinal Ximenez [Cisneros] consented to acknowledge him as regent, and carry on the government in conjunction with him. However, Adrian and his Flemish associates in the administration soon rendered themselves exceedingly obnoxious by their utter incapacity, their corruption, and their griping avarice. The laws of the kingdom were completely disregarded, the high offices of the state either given to foreigners or sold to the highest bidder; and the revenue of Spain, instead of being spent at home, found its way into Germany: the sovereign himself, who was far from his natural dominions, was a candidate for the imperial throne, then vacant by the death of his grandfather Maximilian. All these causes of discontent, increased by Charles's disregard to the remonstrances sent him by the Cortes, spread widely through the Peninsula. The city of Toledo was the first to show symptoms of rebellion. On the arrival of Charles at Valladolid for the purpose of receiving from the Cortes assembled there the oath of allegiance as heir to the crown of Castile, the deputies of Toledo were entrusted by their constituents with a lengthy memorial containing their grievances. Though Charles did not openly deny their petition, he referred them to the Cortes about to be assembled at Santiago, and quitted Spain to take possession of the Imperial crown.

When the people of Toledo heard that the deputies assembled in Galicia had voted the emperor a free gift without obtaining redress of any of their grievances, they rose tumultuously in arms. Their first act was to seize upon the Alcazar, a royal palace and fortress on an eminence commanding Toledo, and after appointing Padilla to be their leader, to establish a popular form of government. Segovia, Toro, Salamanca, Murcia, and Avila followed the example. A general meeting was convened at Avila, and a solemn league formed for the mutual defence of their rights, the direction of affairs being entrusted to a council composed of the deputies of all the towns, under the name of *Junta de las Comunidades*. In the meanwhile Adrian, who resided at Valladolid, then the capital of Spain, sent a body of troops under Ronquillo, to chastise the rebels; but while he was besieging Segovia, Padilla, with a body of insurgents from Toledo, came to the assistance of the citizens, and defeated the royal troops. The next step of Padilla was to march upon Tordesillas, the place where queen Joanna, Charles V.'s mother, had resided since the death of her husband. Being admitted to the presence of the princess, who had long been in a state of mental debility, Padilla and his followers renounced the authority of the regent, and placed her at the head of the government. From thence they proceeded to Valladolid, and deposing Adrian, seized upon the archives and the seals of the kingdom. The Junta then drew up a lengthy remonstrance, containing a state of their grievances, and sent with it two of their number to the emperor. Everything now augured success to the cause of popular liberty, but dissension soon broke out in the ranks of its supporters. The Junta, relying on the unanimity with which the nation had submitted to their authority, and seeing no royalist forces on the field to obstruct their designs, began seriously to think of reforming several political abuses, and various measures were proposed and carried, which struck no less at the privileges of the nobles than at the prerogatives of the crown. This produced a union of the nobility with the royalists. The Junta, who now became jealous of Padilla's popularity, deprived him of the command of their forces, and appointed Don Pedro Giron, the eldest son of the Conde de Ureña, a nobleman of high rank, but wholly unequal to the task entrusted to him.

In December, 1520, the royalists, under the Conde de Haro, defeated the popular army, attacked and took Tordesillas, released queen Joanna, and regained possession of the archives and seals of the kingdom, besides making fourteen members of the Junta prisoners. This severe blow was followed by the immediate disbandment of the insurgents and the loss of their general, who, betraying the cause of the people, passed over to the royalists. Padilla was now raised to the command of the army. He was at first successful in various small encounters, and by means of skilful manœuvres succeeded in avoiding a general engagement with the veteran troops of Charles; but at length the royalists closing upon him on all sides, he was obliged to hazard a battle, in which he was completely defeated at Villalar, 23rd of April, 1521.

Padilla, who had been severely wounded in the conflict, was made prisoner, together with some of his principal officers, and executed on the day following that on which the battle was fought. Sandoval, and after him Dr. Robertson, have preserved us two letters, full of eloquence and manly feeling, which the illustrious martyr of liberty wrote a few hours previous to his execution; one addressed to the city of Toledo, the other to his wife Doña Maria Pacheco, in which are some remarkable passages breathing respect and filial love towards his father Pedro Lopez, who fought against him under the royal banners.

PADILLA, DOÑA MARIA PACHECO DE, the offspring of one of the most illustrious families in Spain, was early married to John of Padilla, whose political principles she embraced, and whose cause she most strenuously defended. After the execution of her husband, she swore to support the sinking cause of the people, and to revenge his fate. The citizens of Toledo, who had learned on former occasions to appreciate her virtues, entrusted her with the defence of their rights. The prudence and vigour with which she acted justified the confidence placed in her. She wrote to the general of the French, who had just invaded Navarre, to advance into Castile, promising him her powerful aid. In order to procure the money requisite for raising an army, she went in person to the cathedral of Toledo, where a vast treasure of ecclesiastical wealth was preserved; and entering the temple in solemn procession with all the marks of the deepest sorrow on her countenance, proceeded to take possession of the sacred deposit. She moreover adroitly put into practice every artifice that could interest or inflame the populace. For this purpose she ordered her troops to use crucifixes instead of crosses, and she marched through the streets with her son, a young child, dressed in the deepest mourning, seated on a mule, and having a standard carried before him, on which was represented his father's execution. All her efforts were however fruitless: the rebellion, now confined almost within the walls of Toledo, was speedily crushed in other parts of the Peninsula. By the total discomfiture of the French, who were obliged to repass the Pyrenees in haste, all the royalist forces were brought into operation; and Toledo, the last refuge of the Comuneros, was invested. Though she defended herself with the greatest courage for four months within the walls of the citadel, the clergy, whom she had highly offended by her spoliations, ceasing to give her their support, she was obliged to surrender that fortress. It appears however that the means were facilitated to her of making her escape; for she fled to Portugal, where she passed the remainder of her days. Thus ended this bold though unsuccessful attempt of the commons to assert their rights, which contributed greatly to increase and extend the power of the crown. With the exception of the graphic and admirable sketch by Dr. Robertson, in his 'History of Charles V.,' we possess no other history of these important events but what has been preserved by the Spanish writers, who are all in favour of the rights of the crown. There are in the library of the British Museum two inedited manuscripts containing an account of these wars, which were unknown to Dr. Robertson. Martinez de la Rosa is the author of a tragedy entitled 'Maria de Padilla.'

(*Relacion de las Comunidades, MS. Bib. Egerton*, in the British Museum, No. 303; *Tratado de las Comunidades*, ib., No. 310; Robertson's *Charles V.*, vol. ii (sixth edit.); Sandoval, *Hist. de Carlos V.*; Martinez de la Rosa, *Bosquejo de la Guerra de las Comunidades*, vol. iii.)

PADILLA, LORENZO DE, one of the historiographers to Charles V., was born at Antequera, a town of Andalusia, towards the end of the fifteenth century. When still young he was, owing to his eminent virtues and profound learning, raised to the dignity of archdeacon of Ronda in the diocese of Malaga. At the same time he was appointed historiographer to the crown, when he devoted his time entirely to the study of the antiquities and history of his native country. Padilla died in 1540, leaving behind him a general history of Spain, divided into four parts, a few sheets of which have been printed, according to Nicolas Antonio (*Bib. Nov.*, vol. ii.), a circumstance which proves that the whole work was committed to the press, though the impression was probably never completed. The original manuscript was still existing at the end of the last century in the library of the convent of St. Paul at Cordova, but has since disappeared. Florian de Ocampo, Padilla's successor in office, has been accused of appropriating to himself a voluminous treatise of this writer on the antient geography of Spain, which he inserted almost entire in the first books of his 'Cronica General de España.' Besides the above works, Padilla wrote the following: 'Catalogo de los Santos de España,' Toledo, 1598, fol.; and 'Libro de las Antiguedades de España,' afterwards edited by Pellicer, Valencia, 1669, 12mo. The following are still inedited:—1, 'Geografia de España;' 2, 'Nobiliario o Linages de España;' 3, 'Origen y Sucesion de los Principes de la Casa de Austria hasta el Rey Don Felipe;' 4, 'Catalogo de los Arzobispos de Toledo.'

(Nicolaus Antonius, *Bib. Nov. Script. Hisp.*, vol. ii., p. 6.)

PADOLLUS, De Montfort's name for those species of the genus *Haliotis* which are distinguished by a large parallel rib hollowed interiorly, &c. [HALIOTIDÆ, vol. xii., p. 16.]

PA'DOVA, THE PROVINCE OF, called by the English *Padua*, one of the provinces of the Lombardo-Venetian kingdom, is bounded on the north by the province of Treviso, on the east by that of Venice, on the south by that of Rovigo, and on the west by the provinces of Vicenza and Verona. The province of Padua consists almost entirely of a plain crossed by the rivers Brenta, Bacchiglione, Gorzone, and others, and sloping to the eastward towards the lagoons of Venice. The Adige forms the southern boundary of the province, and divides it from that of Rovigo. A small part of the territory, about one-twentieth, is occupied by a range of hills called the Euganean Hills, which are of volcanic formation and well cultivated; they run south-west of the city of Padua, and divide the waters of the Bacchiglione from those of the Adige. The length of the province is about 40 miles from north to south, and its greatest breadth is about 30 miles, but in other places it does not exceed 15 miles. The area is reckoned at 836 square miles. (Quadri, *Prospetto Statistico delle provincie Venete.*) The province of Padova is the most fertile and the most densely peopled of the Venetian provinces which now form part of Austrian Italy. The population in 1833 was estimated at 284,000 inhabitants. (Serristori, *Saggio Statistico dell' Italia.*) The province is divided into twelve districts, namely, Padova, Monselice, Montagnana, Este, Mirano, Noale, Camposampiero, Piazzola, Teolo, Battaglia, Conselve, and Piove, which contain in all 103 communes. A number of canals, some for navigation and others for irrigation, intersect the province, which produces wheat, Indian corn, pulse, oil, wine, flax, hemp, chesnuts, potatoes, fruits, and hay. The number of horned cattle is reckoned at about 46,912 head, that of horses at 8000, sheep 52,000, and swine 20,000. The other products of the country are silk, wool, wax, and honey. The manufactories are few, and consist chiefly of tanneries, silk spinneries, woollen cloth, and hats. The city of Padova has several presses for printing and engraving.

The principal towns are the following: PADOVA; Este, a town of about 8000 inhabitants, has given name to an illustrious sovereign family; Montagnana, with about 8000 inhabitants, has some tanneries and hat-manufactories; Abano, with 2000 inhabitants, is noted for its mineral waters and mud, of which Stewart Rose gives a description in his 'Letters from the North of Italy;' Battaglia is also frequented for its mineral springs. Near Battaglia are the fine mansion and grounds called 'Il Catajo,' which belonged to the noble family of Obizzi, the last of whom bequeathed it to the present duke of Modena. A few miles from it is the village of Arquà, in a delightful situation on the Euganean Hills. Arquà contains the house in which Petrarch breathed his last:

> They keep his dust in Arquà, where he died;
> The mountain-village where his latter days
> Went down the vale of years; and 'tis their pride—
> An honest pride—and let it be their praise,
> To offer to the passing stranger's gaze
> His mansion and his sepulchre; both plain
> And venerably simple, such as raise
> A feeling more accordant with his strain
> Than if a pyramid form'd his monumental fane.'
>
> 'Childe Harold,' canto iv.

PADOVA, in English *Padua*, the antient Patavium, a town of the Veneti, known as the birth-place of the historian Livy, and now a town of the Lombardo-Venetian kingdom, is situated in a fertile plain, in 45° 25′ N. lat. and 11° 53′ E. long. The river Bacchiglione flows by its walls. Padova is enclosed with walls, ditches, and bastions, and is above six miles in circumference; but it is thinly inhabited, the population not exceeding 47,000 inhabitants (Serristori, *Saggio Statistico*), though it has been increasing of late years. Most of the streets, especially in the old part of the town, are narrow and lined with arcades; it has however some fine squares and handsome gates. The principal buildings are: 1, the cathedral, begun in the twelfth century, but finished only about the middle of the eighteenth; it has some good paintings and several sepulchral monuments of learned men, among others that of Sperone Speroni, a philosopher, orator, and poet of the sixteenth century; and a bust of Petrarch. The baptistery, which is detached from the church, has some fine old paintings of the Florentine school. 2, The episcopal palace has also some valuable paintings, among others a bust of Petrarch in fresco, which was cut out of the wall of the poet's house, and is considered the best likeness of him. 3, The church of St. Anthony, built by Nicola di Pisa; it is very rich in paintings, sculpture, and other ornaments, besides containing many sepulchral monuments of illustrious men, such as Bembo, the patrician Cornaro, Cesarotti, and others. The chapel of the titular saint is one of the richest in the world; its treasury, consisting of numerous offerings made by the pious, was partly stripped of its riches by the French in 1797. St. Anthony is the patron saint of Padova, and his church is one of the most splendid in Italy. In the square before the church is a fine bronze equestrian statue of Gattamelata, captain-general of the Venetian troops, by Donatello. 3, The church of Santa Giustina, a handsome piece of architecture, with eight domes and numerous chapels and paintings; its antient and valuable library was sold in 1810 by Napoleon's government, and the books and MSS. have been dispersed all over Europe. 4, The church of the Eremitani, built in the thirteenth century, contains several remarkable old fresco paintings, and some sepulchral monuments of the family of Carrara, once the rulers of Padua. Padova has many other churches, most of which are worthy of notice. That of Santa Croce deserves mention for the tomb of Father Stellini, a man of vast and multifarious erudition, a poet, mathematician, and metaphysician, one of the profoundest thinkers that Italy has produced, and yet he is now nearly forgotten in his own country. 5, The building of the university, called the palace, is large and commodious, having a court, with two ranges of galleries one above the other, an anatomical theatre, a cabinet of natural history begun by Vallisneri, a botanical garden, an observatory, and a library with upwards of 70,000 volumes. There are several colleges in various parts of the town. The university, which is one of the principal in Italy, was founded by the emperor Frederic II. in the first part of the thirteenth century. It flourished most after Padua came under the dominion of Venice, when it had six thousand members. The number of students is now about one thousand. There are about sixty professors, several of whom are well known in the scientific world. A rector, annually chosen from the body of professors, is at the head of the university. The university has four faculties, theology, law, medicine, and philosophy. 6, The clerical college or seminary of Padua is noted for its printing-presses, which have long supplied Italy with school books, and with good editions of other works. At Padua Forcellini compiled and published his great Latin Lexicon, upon which he spent forty years of his life. The library of the seminary contains 55,000 printed volumes and about 800 MSS. 7, The palace of justice, 'palazzo della ragione,' or town-house, is a vast structure: the great hall, the largest in Europe, is nearly 300 feet long, 100 feet wide, and 100 feet high; it is ornamented with frescoes and with monuments of illustrious Paduans, among others one raised in honour of Livy, and another to Belzoni, with two Egyptian statues of granite given by that traveller to his native city. At one end of the hall is the 'lapis vituperii' mentioned by Addison; it is a seat of black stone upon which insolvent debtors were obliged to sit with their bare posteriors, as in other towns of Italy, in the middle ages. 8, The palace called 'del Capitanio,' once the residence of the Carrara family, is remarkable for its handsome gate, its great court, and its tower. The town library is in one of the halls of this palace. 9, The palace Giustiniani is remarkable for its fine architecture among the other palaces of the Paduan nobility. 10, The new building, called the 'Caffè Pedrocchi,' is both a coffee-house and casino or assembly-rooms; it is entirely cased externally and internally with marble, and is one of the most splendid establishments of the kind in Europe.

The Prato della Valle, or public promenade, is adorned with numerous statues of distinguished Italians. The academy of sciences, letters, and arts of Padova, instituted in 1779, publishes its memoirs, which form nine or ten volumes 4to. Besides the learned men to whom Padova has given birth, Petrarch resided here a long time, holding a canonry in the cathedral, and he died at Arqua, a few miles distant; and Galileo was for eighteen years professor in the university.

Patavium was considered in the Roman times as one of the oldest towns of Italy, and there was a tradition of its having been founded by the Trojan Antenor. Patavium was long in alliance with Rome, and had its own magistrates. At the fall of the Roman empire, it was destroyed by Attila, and the inhabitants removed to the islands in the lagoons, where they founded Venice. Patavium was rebuilt by Narses, ravaged by the Longobards, and restored by Charlemagne. It afterwards governed itself for a long time as a free municipality with its consuls and podestas. In the thirteenth century Ezzelino da Romano usurped the sovereign power, but after his death the Paduans not only regained their freedom, but extended their authority over several adjacent provinces. Soon after the Carrara became lords of Padova, until 1406, when Venice took it by force and united it to its territory, and caused its last lord Francesco Carrara and his two sons to be strangled in prison. Numerous writers have written on the history and monuments of Padova: among the rest, Scardeonius, 'De Antiquitate Urbis Patavii et claris Civibus Patavinis,' fol., 1560; Gennari, 'Annali della Città di Padova,' 3 vols. 4to., 1804; Facciolati, 'Fasti Gymnasii Patavini,' 2 vols. 4to., 1757; Moschini, 'Guida per la Città di Padova,' 1817; Federici, 'Dissertazione Storica della Biblioteca di Santa Giustina in Padova,' 1815.

PADOVANI'NO. [VAROTARI.]

PADRIES. [SUMATRA.]

PADSTOW. [CORNWALL.]

PADUA. [PADOVA.]

PADUANI'NO, FRANCESCO, was born in the year 1502. The name of the master under whom he studied seems not to be known. Judging by his works, he must have acquired his knowledge of the art in a good school. He was an artist of eminent talents. His historical pictures prove his abilities and taste. His invention was fertile and refined, and his drawing correct and elegant. In the church of the Madonna dei Carmini at Venice there was (and perhaps still is, but we cannot positively say) a picture by this master representing the deliverance of two persons condemned to death, by the interposition of a saint. It is a beautiful performance: the colouring is good, the figures elegant, and the pencilling remarkably tender and delicate. As a painter of portraits he was equal to the greatest masters in that branch of the art. There was such dignity, expression, and beautiful colouring in them, as to gain universal admiration. His portraits of the Earl and Countess of Arundel are spoken of as decisive proofs of his merit. He died in 1617, at the age of sixty-five, leaving a son, Octavio, who studied first under his father, and afterwards for several years at Rome. He painted in the same style as his father, but was inferior to him in invention. His chief excellence was as a portrait painter. He died at the age of fifty-two, but in what year is uncertain.

PÆAN (*παιάν, παιών*, Ionic *παιήων*), a hymn which was originally sung in honour of Apollo, obtained its name from that of the god to whose honour it was sung. In Homer, Pæan (*παιήων*) is spoken of as a separate individual and the physician of Olympus (*Il.*, v. 401, 899; compare Pind., *Pyth*, iv. 481); but there appear sufficient reasons for supposing that this god is the same as Apollo. The pæan was sung at all the solemn festivals of Apollo, as for instance at the Hyacinthia (Xen., *Ag.*, ii. 17). The pæan was a loud and joyous song, and was therefore sung at the cessation of a plague (*Il.*, i. 473) and after a victory. It was also sung by the Greek troops previous to an engagement (Xen., *Anab.*, i. 10, s. 7, &c.), and was called by the Spartans on that occasion *παιὰν ἐμβατήριος* (Plut., *Lyc.*, c. 22). The Scholiast on Thucydides (quoted by Sturtz, *Lex. Xenoph.*, vol. iii., p. 384) says, that the pæan which was sung before a battle was sacred to Ares, and the one sung after to Apollo; but whether this be the case or not, it is certain that the pæan was sung in honour of other gods as well as of Apollo. Xenophon, for instance, relates that the Lacedæmonians on one occasion, after an earthquake, sung a pæan to Poseidon (*Hell.*, iv. 7, s. 4), and also that the Greek army in Asia sung a pæan to Zeus (*Anab.*, iii. 2, s. 9). It was also the custom to sing a pæan after an entertainment. (Xen., *Symp.*, ii. 1; Athenæus, iv. 27, p. 179. Compare Müller's *Dorians*, vol. i., p. 319, 320, 337, 384, transl.)

PÆCILOPODA, erroneously printed as a reference from Cecrops for Pœcilopoda.

PÆDO-BAPTISTS (those who baptise children, from *παῖς* and *βαπτίζω*), a term used by modern theological writers, not as the designation of any particular body of Christians, but for the sake of distinguishing all those, of whatever sect, who practise infant baptism, from the body who are called Baptists. [Baptists.]

PÆO'NIA. [Macedonia.]

PÆO'NIA is a genus chiefly of European and Asiatic plants, belonging to the natural order Ranunculaceæ, and very generally cultivated in gardens for the sake of their large gaudy flowers. They are characterised in their order by a permanent leafy calyx of 5 unequal sepals, 5 petals, stamens whose anthers split open by two fissures along their face, a fleshy elevated disk, and from 2 to 5 many-seeded carpels, terminated by a fleshy recurved stigma. Their fruit consists of leathery follicles, splitting on one side, and exposing to view a number of round, black, shining seeds adhering to a crimson placenta.

One species, *P. Moutan*, a native of China, is a shrub, of which several varieties, with beautiful whitish flowers stained with pink, are now in our gardens. Of these the most showy is that called *P. papaveracea*, which has a broad crimson stain at the base of each petal. If grown on the north side of a wall, or in a situation where it is but little exposed to the sun in the early part of the day, this species will bear the open air of England without protection; but it sprouts so early in the spring, if exposed to the sun, that it is very liable to be cut off by the late frosts of England. Of the other species, *P. Brownii* and *californica* are remarkable for being the only species inhabiting America; they are natives of California and of the country to the northward, and have little beauty: the first exists in our gardens, but is extremely rare. The rest of the genus consists entirely of European and Asiatic plants, which, according to De Candolle, form fifteen species; but there can be no doubt that the greater part of these supposed species are mere varieties, chiefly of *P. officinalis*, *albiflora*, *tenuifolia*, and *peregrina*.

All these plants are liable to produce double flowers, which, by the conversion of their numerous stamens into petals, are generally extremely beautiful: they have however no smell, or not an agreeable one. Being quite hardy, growing readily in any kind of soil, and easily multiplied, either by seeds or by division of the roots, they are generally favourites in gardens.

All the species have an acrid principle concentrated in their roots and seeds, which are accordingly emetic and cathartic in moderate doses. They were formerly in great repute as a medicine; and Dioscorides, whose *Παιωνία* was probably both *P. officinalis* and *peregrina*, gives no fewer than sixteen names by which it was known.

PAER, FERDINANDO, was born at Parma, in 1774 according to his own account, and received his first instructions in music at the Conservatorio della Pietà, in his native city. It is stated that he produced an opera, *Circe*, at Venice, when he was only ten years of age, and that this was successful; but to relations of so marvellous a kind we are slow in giving credit. Either the composer was older than is supposed when his first essay was performed (which we believe to be the case), or the opera must have been a mere sketch by the child, reduced to order and filled up by an experienced musician. After remaining some years at Venice, he visited all the great cities of Italy; then returning to the place of his birth, the grand-duke, his godfather, settled on him a pension, which, putting him in a state of independence, enabled him to gratify an ardent desire to study the various branches of polite literature, poetry in particular, and to this may be ascribed that judgment in setting words to music which is so conspicuous in all his compositions.

In 1795 Paer accepted an invitation to Vienna, where he produced three or four operas, and also some cantatas for the empress Theresa. In 1801 he succeeded Naumann as *kapellmeister* at Dresden, and there brought out his *Leonora* and *I Fuorusciti*. Here he was introduced to Napoleon after the battle of Jena, and thenceforward was taken into the emperor's service, whom he attended to Posen and Warsaw, and afterwards to Paris, where he was appointed Imperial composer and conductor of the chamber music of the empress Marie-Louise, The favour he had enjoyed at the court of the Tuilleries was not discontinued on the restoration of the Bourbons, by whom he was noticed in a marked manner. In 1818 he undertook the direction of the Opéra Italien, which office he held till the year 1825, when, from alleged motives of economy, but in fact through theatrical intrigue, he was superseded. The mortification produced by this dismissal was in some degree alleviated by his election as a member of the Institute; but the treatment he had received visibly affected him till his death, which took place at Paris in 1839.

Among the many operas by Paer, his *Agnese*, *Griselda*, *Achille*, and *Sargino*, give him a title to be ranked among the first masters of the age; and all his other works exhibit skill in design, excellent dramatic arrangement, and masterly accompaniments. He knew how to turn his materials to the best advantage, and to a considerable share of genius added that superior taste which is the result of strong natural sense and feeling properly cultivated and directed.

PÆSTUM, POSEIDO'NIA, an antient town of Lucania, about four miles south-east of the mouth of the Silarus, near the coast of the Gulf of Pæstum, now the Gulf of Salerno. The surrounding country, which is low and marshy, lies between the sea and an offset of Mount Alburnus, which divides it from the valley of the Calore, an affluent of the Silarus. The sulphureous springs which are in the neighbourhood form stagnant pools, and a stream, noticed by Strabo, and now called Fiume Salso, which flows past the walls of Pæstum, by overflowing the low grounds adds to the unwholesomeness of the atmosphere. The whole lowland is deserted, and the only villages are on the hills. The remains of Pæstum are about twenty-five miles south-south-east of the town of Salerno; they consist of the town walls, two fine Doric temples, another building, and a small amphitheatre. Remains of a Roman temple are said by Valéry (*Voyages en Italie*) to have been discovered in 1830, between the two older temples, but they are probably the same as those already noticed by Swinburne in 1783 as being then in a very dilapidated state.

The origin of Pæstum is involved in obscurity. According to Solinus it was a colony of the Dorians, but others pretend, though apparently without any authentic grounds, that it was first a Phœnician settlement, and was afterwards colonised by the Dorians. (Mazocchi, *Commentarii in Tabulas Heracleenses*.) Others again ascribe its foundation to as Tyrrhenian Pelasgi, and the peculiarly massive construction of the walls seems to correspond with the character of the other structures attributed to that people. Medals with Etruscan characters have been found at Pæstum, in which the town is called Phistlus, Pistlu, and also Sistlus. (Hamilton, *Antiquities*, vol. i., 95-96; Paoli, *Dissertationes*.) Whoever were the founders, there is reason to believe that Pæstum existed as a town before it was colonized by the Sybarites, according to Strabo and others. Sybaris was not a Dorian colony, but it is stated by Aristotle (*Politics*, v. 3) that a band of Trœzenians had a share in its foundation together with the Achæans, and that being driven away by the latter, they went to found a new settlement in another part of the country. These Trœzenians are supposed by some to have been the colony that occupied Pæstum, and gave it the name of Posidonia, or the city of Poseidon. (Raoul Rochette, *Histoire des Colonies Grecques*.) Herodotus (i. 167) says that the Phocæans (who had fled away from Asia Minor in the time of Cyrus) landed on the coast of Œnotria and founded Hyela, having for leader a man from Posidonia. The site of Hyela, afterwards called Elea and Velia, and of which no traces remain, was to the south-east of Pæstum, beyond the river Heles, now Alento.

The medals of Posidonia shew by their devices, which consist of anchors, oars, rudders, and other nautical implements, that the inhabitants were a seafaring people. Strabo says that the Lucanians took Posidonia from the Sybarites, and the Romans afterwards took it from the Lucanians, and it must have been under them that the inhabitants lost by degrees their Greek manners and refinement, a circumstance which we find deplored by Aristoxenus of Tarentum (Athenæus, xiv. 7); and this is confirmed by Strabo (vi. 253), who says that, with the exception of Neapolis, Tarentum, and Rhegium, all other Greek towns in Southern Italy had become barbarised, being occupied, some by the Lucanians, others by the Campanians, though all in reality under the dominion of Rome. Livy places under the year 422 of Rome a battle fought in the neighbourhood of Pæstum by Alexander king of Epirus against the Samnites and Lucanians united, who were defeated. Half a century later, at the end of the war against Pyrrhus, the Romans are stated to have sent colonies to Posidonia and Cosa. (Livy, *Epitome*, xiv.) Livy afterwards (xxii. 36, and xxvi. 39) speaks of Pæstum as of a town allied to Rome, and willingly assisting Rome, like its neighbours of Velia and Neapolis, in the great contest against Hannibal; and in another place (xxvii. 10) Pæstum is numbered among the eighteen faithful Latin colonies which did not forsake Rome in the time of danger. Strabo (v. 251) observes that 'the country between the Samnites and Campanians and the Tyrrhenian Sea as far as the Frentani, was inhabited by the *Picentini*, a colony of the Piceni from the Adriatic coast, who had been forcibly removed by the Romans to the shores of the Posidonian or Neptunian Gulf, now called Pæstan, the town of Posidonia being named *Pæstum*.' In two inscriptions of the Roman time existing at Naples, Pæstum is styled a municipium. Nothing is known of it under the empire, but the surrounding country is celebrated by Virgil, Ovid, and other Roman poets, for the abundance and luxuriance of its roses, and the 'Pæstanæ valles' are extolled for their fertility, a quality which they have retained to this day. The country south-east of Pæstum as far as *Capo Palinuro* is one of the finest districts in the kingdom of Naples, and is known by the name of 'Il Cilento,' from the river Alento, which flows through it.

Bishops of Pæstum are mentioned in the annals of the church in the fifth century of our æra. A bishop named Florentius attended the council of Rome under pope Symmachus, A.D. 499. In the tenth century, the Saracens, having invaded this part of the country, formed a settlement at Agropoli, in the neighbourhood of Pæstum, where they fortified themselves, and long resisted all the efforts of the dukes of Beneventum and the Greeks to expel them. That was the period in which they devastated Beneventum, Sora, Matera, and other towns; and it seems that Pæstum was ruined about the same time, and the episcopal see was removed to Capaccio on the neighbouring mountain. In the following century, after the expulsion of the Saracens, king Roger the Norman ransacked the temples and other monuments of Pæstum of their marble and other ornaments, to adorn the cathedral which he raised at Salerno.

During the middle ages the remains of Pæstum lay unnoticed, though not unknown, as some people have gratuitously stated, for the temples are conspicuous objects from almost every part of the Gulf of Salerno, and there is nothing between them and the sea to obstruct the view. But the truth is that the natives were careless of those things, and the country having become unwholesome and infested by outlaws, strangers did not venture into it. When Don Carlos Bourbon, having conquered Naples towards the middle of the last century, became the resident sovereign, he revived the taste for the arts and antiquities. Count Felice Gazola of Piacenza, an officer in his service, having been appointed commandant-general of artillery, had occasion to visit that coast, and being himself a man of taste, he admired the temples and other remains in that solitary region, and took drawings of them, with the intention of having them published; but king Charles having removed to Madrid, Gazola followed him thither. Mazocchi, in 1754, in his work on the Heraclean Tables, inserted a dissertation on Pæstum and its history, and mentioned Count Gazola as having again brought to notice the remains of that once illustrious city. Winkelmann, who visited Pæstum in 1758, has made some remarks on the temples in his introduction to his 'Anmerkungen über die Baukunst der Alten.' About the same time Pasquale Magnoni wrote a work entitled 'De veris Posidoniæ et Pæsti originibus Dissertatio,' without date. In 1767 appeared in London the first description of Pæstum, 'The Ruins of Pæstum,' fol., with 8 plates, anonymous, which was followed by Major's work, which had the same title, in 1768. In 1769 a French translation of the former work, in 4to., with plates, was published at Paris, and in the preface to this translation the plates were said to be derived from drawings taken on the spot by a French artist named Soufflot, as early as 1750, and some of which had been engraved and published at Paris, by M. Dumont, in 1764. As the plates however of these works, according to Father Antonio Paoli, were incorrect, except those that were borrowed from Gazola's drawings, which he had shown to some friends, Gazola commissioned some persons at Naples, among others Father Antonio Paoli, to compare his drawings with the originals, and prepare them for publication. Gazola having died in Spain in 1780, Paoli became the depositary of his papers, from which he published his fine work, 'Pæstanæ Dissertationes,' Italian and Latin, with sixty-three plates, thirteen of which are of Posidonian coins, and a topographical map, fol., Rome, 1784. Delagardette's 'Ruines de Pæstum' was published at Paris in 1797. The 'Magna Græcia' of Wilkins also contains descriptions and architectural drawings of the temples.

PÆSTUM, ARCHITECTURE OF. It is somewhat singular that while the Italian artists, unacquainted with Grecian examples, took the writings of Vitruvius as their canons for the different orders, there existed at no great distance from the city of Naples examples of primitive Doric architecture of far more severe character and more massive proportions than any in Greece itself, if we except the temple at Corinth. Mazocchi, in his work above referred to, observes that the monuments at Pæstum could not be referred to any of the architectural orders of Vitruvius; but he does not appear to be aware what they really are.

These structures, now almost the sole evidence of the opulence of Posidonia or Pæstum, are three in number, and two of them in tolerably perfect preservation. The solidity of their construction almost bids defiance to all attempts to destroy them for the sake of their materials; while other ruins within the walls of the city plainly attest how completely the work of destruction has been carried on around them. Even of the amphitheatre nothing now remains but traces of its general form and winding vaults. According to Paoli, the architecture of the Pæstum temples is to be considered rather as Etruscan than Grecian; yet whatever may be the country of the architects, there is no disputing that the buildings themselves essentially belong to the Doric style, their distinct character in that respect rendering their peculiarities all the more striking. We find here precisely the same features and members, only with a difference; and moreover precisely the same disposition. In fact it is only for the differences of the kind alluded to that these temples are at all remarkable; since in their plans and all other particulars they present nothing more than what is common to nearly all Greek temples, namely, a cella surrounded by external colonnades, or peripteral.

Both those at Pæstum are peripteral and hexastyle, the only difference between them being that the larger one has fourteen columns on each of its sides (reckoning again those at the angles), and the other only thirteen. The first (which is 195 feet long by 79 wide) is *hypæthral*, or open to the sky; that is, its cella forms an inner court, with a range of seven Doric columns on each side supporting an architrave, on which stands a second range of smaller columns of the same order; which arrangement produces a most uncouth effect. The floor of this cella is raised several feet higher than that of the external colonnades. The external columns are of extraordinary massiveness, being seven feet in diameter at their base, though only 29·10′ high; and as their upper diameter below the capital is not more than 4·9′, their shafts decrease very suddenly; one, though not the most unfortunate consequence of which is, that, as compared with the necking of the column, the capital and abacus spread out exceedingly. Another singularity is that the architrave does not at all overhang the upper part of the columns, its soffit being of the same thickness as the top of their shafts beneath their capitals; whereas in nearly all examples of the Grecian Doric the face of the architrave is in a plane that would intersect the shaft of the column nearly at its base.* In comparison with the height of the columns, the entablature is exceeding deep and ponderous, being equal to one half of that of their shafts exclusive of the capital; which unusual massiveness of the upper part is in perfect accordance with that of the columns.

The smaller temple, sometimes called that of Ceres, as the other is that of Neptune, measures 107 by 47 feet, and, as has been observed, is hexastyle peripteral; though if so far perfectly similar to the one just described, it has one very remarkable singularity in its plan, which is that the pronaos is not formed by columns between antæ, and consequently enclosed at its sides, but has two columns and a half column on each side, which latter is attached, instead of an anta, to the end of the wall of the cella. These columns are raised upon a socle one behind the other, and have small bases. As regards the external order, one very remarkable peculiarity in the detail of the columns is, that for the usual narrow channels and annulets forming the hypotrachelium, or necking beneath the capital, a very deep cavetto, or hollow, is substituted, which is carved. The ornament thus produced has been generally compared to leaves, and some have most fancifully suggested that we here find the first rudiments of foliage for the decoration of capitals; whereas, to say nothing of the utter dissimilarity between such ornament and foliage properly so termed, it consists of what look more like husks than any kind of leaves.

Besides these there is a third building, which has greatly puzzled antiquaries on account of its having an odd number of columns, viz. nine in each front, which circumstance has led them to suppose that it could not have been erected for a temple, but must have been a basilica, palæstra, or other public building. Except however as regards what, owing to there being no remains of pediment to call attention to the central column, does not at all strike the eye, there is nothing whatever in the character of the design to distinguish it from the generality of Greek temples, it being merely a peripteral building (whose dimensions are 177 feet by 75) with nine columns at each end and eighteen on each of its longer sides, those at the angles of the former being reckoned again. The only thing at all remarkable now to be traced in its plan is that it was divided in its breadth by an internal range of columns in the middle, three of which are yet remaining; on which account Hirt conjectures it to have been a double temple, with a single cella divided by a mere screen of columns, and dedicated to the Dioscuri, as the tutelary deities of navigation and the protectors of the port of Pæstum; or rather, according to his restoration of the plan, the part of the cella so divided off was merely a very deep pronaos, having three columns *in antis* in front, and a range of four columns within, forming a double avenue leading to two smaller sanctuaries containing the altars or statues of the respective divinities. Yet as no internal walls now exist, it has generally been supposed that there never was any kind of cella or enclosure within the external colonnades.

The order itself is very remarkable, for besides the neckings of the columns being ornamented somewhat similarly to those of the smaller temple, the shafts are very much curved, so as to seem almost to belly out in their middle, owing to their diminishing very suddenly at about two-thirds of their height, while the contraction just at the necking causes the abacus to appear of extraordinary magnitude, its breadth being in fact considerably more than double the upper diameter of the shaft, whereas in Athenian examples of the order the average proportion of the abacus is only one half more than the upper diameter.

In order to show at one view both the actual dimensions and proportions of the columns, we give them in feet and inches, without regard to fractional parts of the latter; and that they may be readily compared with the Corinth example, which most nearly approaches to them in massiveness, that also is added. At the same time we are enabled to correct a mistake in the table of Doric examples at page 387 of Column, where the lower diameter is stated to be only 2 feet 5·10 inches, and the upper one 4 feet 4·10′.

		Height of column including capital.	Lower Diam.	Upper Diam.
Great Temple at Pæstum	.	29·10′	7·0′	4·9′
Smaller temple ditto	.	20·4′	4·3′	3 0′
Third temple, or basilica	.	20·10′	4·9′	3 1′
Temple at Corinth	.	23·8′	5 10′	4·4′

PAEZ, PEDRO, a celebrated Jesuit missionary, was born at Olmedo, a town in New Castile, in 1564. Having completed his studies at the college of his order, he was appointed to form part of the mission at Goa, and sailed for that port in 1587. At that time the numerous Portuguese who had resided in Abyssinia since the invasion of Christoval de Gama, being without a patriarch or spiritual director of any sort [Abyssinia], sent to Goa for some priests, when Paez and another Jesuit, named Antonio Montserrat, were despatched by the governor. The two missionaries sailed from Goa in 1588; they touched at Diu, where they made some stay, disguised as Armenians. They then sailed for Muscat, on the 5th of April, 1588. From thence they made for the port of Zeila in Abyssinia; but on their passage thither they were boarded by an Arab pirate, in sight of Dofar (14th Feb., 1589), and carried in irons to the capital of the king of Shael (Xaer in the Portuguese writers). They were at first kindly treated by this sovereign; but he himself being a tributary to the Turkish pasha of Yemen, and bound by treaty to send him all the Portuguese who might fall into his hands, Paez and his companion were sent to Sanáa, the capital of Yemen and the court of the pasha, where they passed seven years in the most dreadful captivity. Being at last released by the intercession of the viceroy of India, who obtained their liberty upon the payment of a thousand crowns ransom for each, the two missionaries returned to Goa in 1596. The ardour of Paez seems not to have been damped by his past sufferings; on the contrary, after spending several years at Diu and Cambova, he embarked a second time for Abyssinia, and landed at Masawa in April, 1603. His first object was to learn one of the most extensively used native dialects, the Gheez, in which he soon acquired such a proficiency as to be enabled to translate into it the compendium of the Christian doctrine written by Marcos George, and to instruct some native children in the dialogues which that work contains. In 1604, Za-Denghel, the reigning monarch of Abyssinia, hearing of the attainments of Paez and the proficiency of his pupils, ordered him to appear at his court with two of them, that he might judge for himself. Paez was kindly received by the king, who conferred upon him all sorts of honours and distinctions. On the following day a thesis was maintained in his royal presence, when Paez's pupils answered every argument adduced by their opponents: the mass was next celebrated, in conformity with the Roman ritual; after which Paez preached a sermon in Gheez with so much success, that the king himself became a convert to the new religion, and wrote to the pope, and to Philip III., then on the throne of Spain, praying them to send him a reinforcement of missionaries. This wish of the monarch, having been made public, proved fatal to him; for the Abyssinian priests, dreading the ascendency which Paez and his followers had attained at court, excited a rebellion, and Za-Denghel was killed in a battle with his revolted subjects, on the confines of the province of Gojam (Oct., 1604). Socinos, otherwise called Melek-Segbed, who sucseeded Za Dengel in the empire, was still more favourable to the views of the Portuguese missionary. Soon after his accession to the throne, he summoned to his presence Paez, who celebrated mass and preached before all his court, assembled for the purpose. He granted him, besides, a large piece of ground at Gorgora, on a rocky peninsula on the south side of the lake Dembea, to build a monastery for his order and a palace for himself. On this occasion, without the assistance of any European, but with the mere help of the natives working under his orders, Paez produced a building which was the astonishment of those who beheld it. A spring-lock, which he fixed upon one of the doors, saved the king's life when an attempt was afterwards made to assassinate him. Paez lived in great intimacy with Socinios, whom he accompanied in all his military expeditions. It was on one of these occasions that he visited Naguina, a town three days' march from the sources of the Nile, and surveyed the neighbouring country, a fact which Bruce endeavoured to discredit, for the purpose of appropriating to himself the glory of being the first European who visited the source of the Abawi, then reputed to be the main branch of the Nile. [BRUCE.] Pedro Paez died in the beginning of May, 1622, at the age of forty-eight, after having the satisfaction of seeing his missionary labours crowned with success, and persuading the king to receive the general confession, and repudiate all his wives but one. Catholicism, thus introduced into Abyssinia, did not long remain the religion of the state. After the death of Socinios (1632), his successor, Facilidas, persecuted the Jesuits and re-established the old creed, which was Christianity, though in a corrupt form. Besides the translation of the Catechism written by Marcos George and other tracts into the native dialect of Abyssinia, Nicolas Antonio (*Bib. Nov.*, vol. ii., p. 225) attributes to Paez a treatise 'De Abyssinorum Erroribus,' a general history of Ethiopia which was supposed to exist in manuscript at Rome, and several letters which have been published in the collection entitled 'Litteræ Annuæ.'

---

* See Column, p. 385, cut of the Greek Doric order of the Parthenon, which besides explaining what is said of the architrave's overhanging the column, will by comparison shew how very much more massive are the Pæstan edifices.

(*Historia de Ethiopia a alta*, by Manoel de Almeida, MS., in the British Museum, No. 9861, fol. 195; Ludolf's *Historia Æthiopica*; Bruce's *Travels*; Salt's *Abyssinia*.)

PAGAN, BLAISE FRANÇOIS, COMTE DE, distinguished both as a military engineer and a mathematician, was descended from a noble Neapolitan family, and born at Avignon in France, in 1604. Under the auspices of his relative, the constable De Luynes, he entered the French army very young, and, no less by his gallantry and talents than by his family connexions, rose rapidly to rank and reputation. At the siege of Montauban he lost his left eye by a musket shot; but this did not check his zealous career of service, and he continued to increase his celebrity as an officer throughout the wars of the reign of Louis XIII., until, being sent into Portugal in 1642, with the rank of maréchal de camp, he had the misfortune to contract a distemper in that country, which entailed the loss of his other eye, and rendered him totally blind, at the early age of thirty-eight years. Being thus incapacitated from further serving his country in the field, he applied himself, with characteristic energy, to study the theory of a profession which he had already successfully practised; and, in 1645, he published his 'Traité des Fortifications,' the ablest essay on the science of defence which the world had yet seen. With no less ardour he had engaged in the kindred pursuit of mathematical research; and the fruits of his labours were exhibited in the publication, in 1651, of his 'Théorèmes Géométriques,' followed, in 1657 and 1658, by a treatise on the planetary theory, and some astronomical tables, all of which were highly esteemed by his contemporaries. He was also the translator of a Spanish account of the river Amazon, accompanied by a chart, the draught of which he is said, though blind, to have drawn with his own hand. With all his mental accomplishments, however, Pagan was not without that common weakness of his age,—a belief in judicial astronomy. But this foible was redeemed by many estimable qualities of head and heart, for which he lived highly respected both in the courtly and the learned circles of his country and times. He died at Paris, universally honoured, in 1665.

The mathematical works of Pagan have lost their value; but, as an engineer, he must ever be numbered among the great masters of the art of fortification. He belonged in fact to that rare order of minds whose creations form an epoch in the history of any science. He corrected the errors and combined the advantages which he found in the systems of the Italian and Flemish engineers; and though he had been preceded in France by Errard and De Ville, and was followed and excelled by Vauban, he may justly be considered as the founder of the French school of fortifying. He signally improved the old defective construction of bastions; he first gave due proportions to their faces, flanks, and lines of defence; and he either originated or adopted the idea of a perpendicular flanking fire, which, though neglected by Vauban, has become the great principle of all the modern systems.

PAGE'LLUS, a genus of fishes of the order Acanthopterygii, and family Sparidæ. This genus, established by Cuvier, contains all those sparoid fishes in which the front teeth are small and prickly, and very numerous; the molars are of a round form, and there are sometimes more than two rows of them; but the two outer rows in these cases are always much the largest. The foremost teeth form a dense mass, and are compared by Cuvier to the bristly points of the carding-machine used in combing wool, a character which distinguishes these fishes from those of the genus *Pagrus*, in which the foremost teeth are conical; the molar teeth moreover are smaller than in the last-mentioned genus. The body is usually of an elongate-ovate and compressed form, and the dorsal fins are continuous. About six European and five extra-European species of Pagellus are known. Two species occur on our own coast: the Spanish Bream (*Pagellus erythrinus*, Cuv. et Val.), which is of a fine carmine-red colour above, passing into rose-colour on the sides of the body, and tinted with silvery white beneath; and the Sea-Bream (*Pagellus centrodontus*, Cuv. et Val.), which is also known by the names of the Gilt-head and Red Gilt-head. The former of these two species is very common in the Mediterranean, but occurs rarely off the British coast. Mr. Yarrell states that he has never seen above two or three specimens, and these were taken with the Sea-Bream, which is also common in the Mediterranean, and by no means uncommon on our own coast.

The following is the description of the Sea-Bream given by the author of the 'History of British Fishes.' The jaws are short, and equal in length; the eye is very large, irides golden yellow; the head short; the line of the profile descends rapidly; cheeks, operculum, and interoperculum covered with scales; the preoperculum and part of the space before and under the orbit have a metallic tin-foil appearance; two narrow stripes are observable on each side behind the head, and these meet on the central line at the top; at the origin of the lateral line, behind the edge of the operculum, is a conspicuous dark patch made up of small spots; the colour of the body is reddish, tinged with grey; lighter on the sides, which are golden grey, and marked with faint longitudinal bands, which extend the whole length of the body: the belly is nearly white, and the dorsal and anal fins are brown, each appearing as if lodged in a groove from the rising edges of the skin and scales along the base; the pectoral fins and tail are red, and the ventrals are grey.

The Sea-Bream is not highly esteemed for the table. It is found most abundantly in the summer and autumn, and apparently leaves the coast in the cold weather. Mr. Yarrell moreover states that the spawn is shed in the beginning of winter in deep water; and in January the young fish, which are called Chads, of about one inch in length, are found in the stomachs of large fishes taken two or three leagues from land: in summer, when from four to six inches long, they abound in innumerable multitudes, and are taken by anglers in harbours, and from the rocks; for they bite with great eagerness at any bait, even of the flesh of their own species. The food, both of the young and adult fish, is not however confined to animal substance, for they devour the green species of sea-weeds, which they bite from the rocks, and for bruising which their molar teeth are well suited, as are their long and capacious intestines for digesting them.

The Spanish Bream is rather more slender in its form than the commoner British species, the eyes are smaller, and the mouth has a wider gape. The colouring is also different; it has not the dark patch which is observable on each side of the body near the head in the Sea-Bream.

PAGO'DA, a corruption of the Sanscrit *bhagavati*, 'holy-house,' is a name generally applied by Europeans to temples in the East, from China to Hindustan. These structures generally consist of a porch, a vestibule or ante-sanctuary for the priests, and an inner sanctuary, containing the principal idol. Some of the Chinese pagodas, or rather the courts enclosing them, are of very great extent, as for instance that of Ho-nang in the south suburb of Conan, the interior area of which is an oblong of 590 by 250 feet, surrounded by cells for the Bonzes, in the centre of which quadrangle are three pagodas or pavilions, each 33 feet square, elevated upon a terrace, and consisting of two stories, the lowermost surrounded by a peristyle of twenty-four columns. Some of the Chinese temples are lofty towers in several stories, diminishing in height and width as they ascend, each having a projecting roof of glazed tiles, and generally ornamented with bells. Among the buildings erected in Kew Gardens by Sir W. Chambers is a lofty Chinese pagoda of this kind; yet although called pagodas by Europeans, the name given by the Chinese themselves to such towers is *Taas*. There is a very celebrated Taa at Nankin, composed of porcelain: it is, like most others, an octagon, upwards of 210 feet high, and divided into ten stories, each of which has a marble gallery with gilt lattices, the stairs being formed within the thickness of the walls. The summit is surmounted by a cupola, from which rises a lofty pole or mast about thirty feet high. Of that at Tong-Tschang-Fou, the exterior is also of porcelain, but the walls themselves are of marble. Others have a single staircase in the centre carried up through all the different stories. Although so completely dissimilar in style, these Taas bear a strong analogy to the Gopuras and Vimanas, or lofty pyramid tower-temples, of the Hindus. [HINDU ARCHITECTURE.] Both seem to have originated in a common idea, differently modified, according to the taste and mode of building of the respective nations.

PAGU'RIANS, a tribe of the apterurous section of the Anomurous family of crustaceans, composed of a considernumber of species, the greater part of which are remarkable for the more or less complete softness of the abdomen, the want of symmetry in the appendages of this part of the body, the shortness of the two posterior pairs of feet, and many other characters. In the greater number, the abdomen is small, nearly entirely membranous, and partially rolled upon itself; and for the protection of this defenceless part the animal lodges it in the turbinated shell, generally, of some gastropod. The crab is retained in the shell by the aid of the posterior feet, and a pair of crustaceous appendages at the end of the abdomen. In some species it is further fixed by means of certain organs on the lower side of the abdomen, to which we shall hereafter allude. The popular names by which these crustaceans are known in Britain and the West India Islands are *Hermit-Crabs* and *Soldier-Crabs*; and in France they are called *Bernards l'Hermite*. They are held so firmly in the shell of which they have possessed themselves, that they move about with it more or less briskly according to its comparative size or aptitude.

ORGANIZATION.

The *carapace* is divided into many portions by lines, which are more or less membranous; one of these depressions or furrows separates it transversely into two halves, the anterior of which constitutes the stomachal region, and is very nearly confluent with the hepatic regions, which are very small, and occupy its posterior angles. The last or posterior half is divided longitudinally into three portions; the median portion constitutes the cardial and intestinal regions, and the two lateral portions form the branchial regions, which last are separated by a similar line from the lateral parts of the carapace, which descend towards the base of the feet. The ophthalmic ring is sometimes hidden above by a rostriform prolongation of the carapace, but is always free, and has above two small prolongations in the form of scales; the *ocular peduncles*, which are directed forwards, are not retractile, and are inserted directly above the *internal antennæ*, which present very variable dimensions, but always have the basilary joint either small or elongated, and are fixed by two short or moderate multiarticulate filaments. The *external antennæ* are inserted on the outside of the internal ones, on the sides of the ocular peduncles; their second joint has, above, a spiniform piece, which is ordinarily moveable, and seems to be analogous to the palp. The external *jaw-feet* are pediform. The *sternum* is nearly linear forwards, and is a little enlarged posteriorly; the two last rings of the thorax are entirely free and moveable, and the last reaches beyond the carapace, and is completed above by a tergal horny piece. e *anterior feet* are large, and nearly always of unequal nensions; they are terminated by a large *manus*, the claws which are short and very stout. The two succeeding pairs are very large; the fourth pair, on the contrary, are short, elevated above the others, and nearly always terminated by a didactylous hand; the fifth pair are equally short, elevated on the sides of the body, and terminated by a more or less well-formed pincer. The first five rings of the abdomen are represented by horny plates of greater or less size, the first of which ordinarily is nearly confluent with the last thoracic ring; sometimes this first abdominal segment is in both sexes furnished with a pair of rudimentary appendages applied against the base of the posterior feet; but in general it is without them. In the male the second segment also is sometimes furnished with a pair of false feet, but in general only gives insertion to an appendage placed on the left side; the three succeeding segments are always deprived of appendages on the right side, and sometimes present none on the left in the male; ordinarily they each support a false foot composed of a basilary cylindrical stem and one or two terminal blades; these appendages, which are consequently four in number, generally, are always very small in the male and rather large in the female, whose eggs they serve to fix. At the extremity of the abdomen are two horny plates, which represent the sixth and seventh segments, and a pair of appendages, nearly always non-symmetrical, and terminated by two stout and short branches, which are fixed to the plate holding the place of the sixth abdominal ring. (Milne Edwards.)

Mr. Broderip, in a paper 'On the Habits and Structure of *Paguri*,' *Zool. Journ.*, vol. iv.), states, that in pursuing his inquiries upon that subject he had been struck with two beautiful provisions in their animal economy. Their backs are towards the arch of the turbinated shell occupied by them, and their well-armed nippers and first two pair of succeeding feet generally project beyond the mouth of it. The short feet rest upon the polished surface of the columella, and the outer surface of their termination, especially that of the first pair, is in some species most admirably rough-shod, to give 'the Soldier' a firm footing when he makes his sortie, or to add to the resistance of the crustaceous holders at the end of his abdomen or tail, when he is attacked and wishes to withdraw into his castle. On passing the finger downwards over the termination of these feet, they feel smooth; but if the finger be passed upwards, the roughness is instantly perceived. The same sort of structure (it is as rough as a file) is to be seen in the smaller caudal holders. The second provision he observed in a very fine and large species of *Pagurus* from the Mauritius (*Pagurus guttatus* of Olivier, he is inclined to believe). Two specimens (now in the British Museum) were in his possession, one of which is housed in a very large young shell of *Pterocerus truncatum*, the other (nearly a foot long) is naked, and on examining the under side of the abdomen or tail of this specimen, a great number of transverse rows of acetabula were to be seen, even without the aid of a glass. Dr. Bright has another naked specimen, in which the same formation, which must very much assist the hold of the *Pagurus*, is visible.

Respiratory System.—MM. Audouin and Milne Edwards, in their interesting memoir, 'De la Respiration aérienne des Crustacés, et des modifications que l'appareil branchial éprouve dans les Crabes terrestres,' show, that in all the crustacea the branchiæ are fitted to perform the functions of respiratory organs in the air as well as in the water, and that one of the conditions necessary to the support of life in animals which have branchiæ and live in the air, is the having these organs defended against desiccation. The provision for this necessary condition in the Land-Crabs will be found in the article GECARCINUS; and the habits of some of the Pagurians demand such a provision, as we shall presently see.

In the museum of the Royal College of Surgeons (Physiological Series, No. 993, D.) is a preparation of a Hermit-Crab (*Pagurus Streblonyx*, Leach), with the branchiæ injected and exposed on both sides. No. 993 of the same series is a small crab (*Cancer Pagurus*, Leach), with the carapace and all the viscera removed except the branchiæ. These are crossed, and, as it were, bound together, by a narrow flattened process, which extends from the anterior part of the branchial cavity. (*Cat.*)

Digestive System.—No. 612 of the Physiological Series in the museum of the College of Surgeons exhibits a Hermit-Crab (*Pagurus punctulatus*, Oliv.), laid open on the ventral aspect to expose its intestinal canal. Its structure and disposition are as simple as that of the Scorpion (*Buthus Africanus*), which immediately precedes it. The canal grows gradually narrower to its termination, which is just below the last crustaceous appendage of the tail. (*Cat.*)

Brain and Nervous System.—In the museum of the Royal College of Surgeons, in London (*Physiological Series*) will be found (No. 1363, B) a Hermit-crab (*Pagurus pedunculatus*, Herbst.) dissected by Professor Owen for the display of the nervous system. The cephalic ganglion is of large size, and transversely quadrate in form; the origins of the large nerves which it gives off to the eyes and antennæ are shown. The lateral chords unite below the alimentary canal to form a ganglion, which supplies the maxillary apparatus; the chords then form a large oblong ganglion situated at the base of the chelæ, and extending to the origins of the second pair of ambulatory feet, both of which pairs it supplies. The lateral chords, greatly enlarged, separate from each other for a short distance, and re-unite to form a third central ganglion, smaller than the second, which supplies the third pair of ambulatory feet, and gives off posteriorly three pairs of nerves. Of these the lateral pair supply the fourth diminutive pair of feet; the mesial pair the fifth; and the dorsal pair, of extremely minute size, are the continuations of the main chords, and pass along the concave side of the soft membranous post-abdomen to the anus, anterior to which a small ganglion is formed, which gives off the nerves to the caudal lamellæ, here converted into clasps, enabling the animal to adhere to the columella of the univalve shell which it may have selected to protect that part of the body which nature has left undefended by a crustaceous covering. (*Cat.*, vol. iii., part 1.)

Senses.—The above paragraph will show the extent to which sight, touch, and taste are developed; and in the same series of the same museum (No. 1559, A) is a Hermit-Crab (*Pagurus Miles*, Oliv.) prepared by the same skilful hands to show the organ of hearing, which is composed of a simple spheroidal cavity situated at the under part of the basal joint of the external antennæ. The cavity is surrounded by a dense crustaceous substance, except at the internal opening, where the auditory filament of the antennal nerve penetrates it, and at the opposite side, where an elliptical opening is left, which is closed by the acoustic membrane; the vibrations of sound affect this membrane, and are transmitted to the nerve, which is exposed on the left side. (*Cat.*, vol. iii., part 1.)

History.—The *Pagurus* of Aristotle is not a Hermit-crab; but he describes three kinds of Hermit-crabs under the name *καρκίνιον* (*Carcinium*). They are termed *καρκινὰς* by Oppian, Ælian, and Galen. Pliny seems to confound them with the *Pinnotheres* or *Pinnophylax*, as is noticed by Aldrovandus. Rondeletius, Belon, and Gesner describe them; the latter very particularly. Jonston's account is little beyond a compilation from the authors above named. Charlevoix ('History of Hispaniola'), says, 'that kind which is called a soldier (soldat) is, as well as the crab, a species of crawfish (écrevisse) or of that sort which is called *Cancellus Marinus*. It is found all along the sea, and is good to eat. It has its name from being armed all over the body, except at the lower extremity, where it is naked, and where it seems to possess great sensibility; it therefore domiciles itself, as soon as it is born, in the first shell it meets with; but to dislodge it, it is only necessary to place it near the fire.'

None of the writers here quoted appear to speak of these animals as being at any time terrestrial, and the others who have given any account of them will be mentioned in the next paragraph, which treats of their habits, &c.

Habits, Food, Reproduction, &c.—Labat mentions 'the soldiers' among the animals that descend every year to the sea to bathe themselves and change their skin or their shell. The old French Encyclopædia defines *Bernard l'Hermite* to be *cancellus*, an animal of the crustaceous genus also called *Soldier*. After a very particular description, the account proceeds thus:—'There are in the isles of America Hermit-crabs (*Bernards l'Hermite*) which are three or four inches in length. They relate that this animal comes once a year to the edge of the sea, to lay its eggs and change the shell; for it is obliged to quit the shell in which it is lodged, because, having increased in size during the year, it finds itself incommoded in that shell. It therefore comes to the shore and seeks a new shell which may be convenient for it. As soon as it meets with one, it comes out of the old one and tries the new lodging, and, if that suits, it remains there; but it is often obliged to enter many shells before it finds one proportioned to it. If it happens that two hermit-crabs stop before the same shell, a dispute arises, and the weakest yields to the strongest.' The same author states, that it pinches hard and does not let go its hold easily, and that the inhabitants eat it, finding it very good, though it does not agree with strangers. This account appears to have been taken from Du Tertre's 'Voyage.'

Sloane thus describes 'the Soldier:'—'This small lobster or crab differs in very little from the European souldier or hermit-crab. It hath two large forked claws like those of an ordinary lobster, one of which is bigger than the other, both rounded, more tumid, less prickly, and of a paler red than that of Europe, &c. They fit themselves with any shell they find empty, whether it be of the land or sea, and cover themselves almost over in it, carrying it on their backs wherever they go, like a snail. It is not possible to believe how quick the land-crabs and this crab will run upon the least appearance of danger. Till they are turned up, nothing appears but a dead shell, the mouth of which lies undermost, out of which some little part of the crab appears after it is taken up.' (*Jamaica.*) Sloane figures two of these animals (apparently *Cenobita Diogenes*) in land-shells (*Helices*), and we saw an individual of the last-named species alive in the shell of a *Helix* at the Garden of the Zoological Society in the Regent's Park.

Catesby, who figures a *Cenobita Diogenes* in the shell of *Turbo Pica*, says, 'They crawl very fast with their shell on their back; and at the approach of danger draw themselves within the shell; and thrusting out the larger claw in a defensive posture, will pinch very hard whatever molests them. They frequent most those parts of the sea-shores which are covered with trees and shrubs producing various wild fruits on which they subsist; though I have seen them feed on the fragments of fish and other animal substances cast on shore. They being roasted in the shell are esteemed delicate. I do not remember to have seen any of them go into the sea.' (*Carolina.*)

Browne notices 'the Soldier' and 'the Common Soldier,' and states that the latter is very common in all the harbours of Jamaica. (*Jamaica.*)

Linnæus says of the *Diogenes* that it inhabits the Asiatic and American Ocean in various shells of *Cochleæ*.

Cuvier, after mentioning univalve shells as the usual covering of the genus *Pagurus* (Fabr.), remarks that some species lodge themselves in *Serpulæ*, *Alcyonia*, &c.; and we have seen individuals lodged in *Alcyonia*. Cuvier also observes that it would even seem that some of the *Paguri* are terrestrial.

Not to detain the reader with those authors whose labours have been principally confined to classification, such as Herbst, Fabricius, Olivier, Latreille, Leach, Duméril, Brisson, Bosc, Risso, and others, we call his attention to the observations of M. Desmarest, who says that these crabs are ordinarily met with on the shallows of flat sea-shores (plages) at a small depth, and may be seen creeping along the bottom by the help of their claws and other fore-feet. Their progress is slow and irregular. They live, like other crustaceans, on small animals of the same class, or on mollusks which pass within reach of their claws and they are able to seize. Naturalists, he adds, make mention of many species of *Paguri* that live on land at a considerable distance from the shore and lodge themselves in holes, and he thinks it probable that such ought to enter into the genus *Birgus*. (*Considérations générales sur la classe des Crustacés.*)

But whatever may have been the form of the terrestrial *Paguri* above alluded to as lodging in holes, the specimens sent to Mr. Broderip by Mr. De la Beche, and forming part of the interesting letter to which we shall presently advert were true hermit-crabs of two species, one *Pagurus* (Cenobita) *Diogenes*, and the other somewhat resembling *Pagurus Prideaux* (Leach). Of the first, there were forty-two of various sizes, and they were housed in the following marine shells, which were, in every instance, well adapted to the bulk of the inhabitant. Two were lodged in *Turbo Pica*, two in *Natica Canrena*, and one in *Bulla Striata*. There were eight in *Fasciolaria Tulipa*, and twenty-nine in *Pyrula Melongena*. Of the latter species of *Pagurus* (the 'Common Soldier' of Browne) there were ten. One was housed in *Fasciolaria Tulipa*, and nine in *Pyrula Melongena*. The shells chosen by these last were large in proportion to the bulk of the inhabitant, so large indeed, that some of the *Paguri* were scarcely visible. The following is an extract from Mr. De la Beche's letter to Mr. Broderip, dated 1st August, 1828:—

'When I was in Jamaica, about three years since, some of the persons on my estate at Halse Hall brought me specimens of *Paguri*, which they said they had obtained from a savannah, distant about a quarter of a mile from the house. This savannah is a plain formed of what I have elsewhere* termed savannah sandstone and conglomerate. It is very dry and covered for the most part with log-wood, green ebony, lignum vitæ, the cashew-tree, and, here and there, with patches of grass and other plants. After heavy rains the surface of the ground is nearly covered with herbage; but, after dry weather, a considerable portion of the soil is exposed. The savannah, which is of great extent (my portion consists of at least two thousand acres), is about thirty feet above the Rio Minho, which runs round the border of it, and about two hundred feet above the level of the sea, from which it is distant at least ten miles. The tide only penetrates just within the mouth of the river, and rises there about eleven inches at the height of the springs, so that there is not even brackish water at a nearer point than ten miles. When the *Paguri* were brought to me, they were alive, and I observed they were housed in marine shells, and at first thought they must have been brought from the sea. Upon inquiry however I found that these animals, under the name of 'soldiers,' were frequently taken alive for food in the savannah, to which I immediately proceeded. On its northern side and at its junction with the hill that rises above it, I found in the little hollows of the white limestone several of these *Paguri*, all in marine shells, and in full health and activity. I afterwards learnt that they were by no means uncommon in such situations all over the island. When I saw them, there had been a good deal of wet weather. They were in moist places, but there were no pools of water.'

Another gentleman, who resided some time in the West Indies, informed Mr. Broderip that he had seen the first mentioned species (*Diogenes*) about his house, when he lived at Port Henderson, and that he had also observed them about the houses at Spanish Town, a place about six miles distant from the sea. Mr. Broderip was also informed that Westmoreland swarmed with them. (*Zool. Journ.*)

Place in the System, and Classification.—M. Milne Edwards, who places the *Pagurians* immediately after the *Hippians* and at the end of the brachyurous crustaceans, divides the tribe into the genera *Pagurus*, *Cancellus*, *Cenobites*, and *Birgus*.

Pagurus. (Fabricius.)

A great resemblance exists among all the *Paguri*, properly so called, not only in the details of their organization, but in their habits. The cephalo-thoracic portion of their body is shorter than the abdominal portion. The *carapace* is nearly as large before as it is behind, and is but little or not at all prolonged laterally above the base of the feet; posteriorly it is strongly notched in the middle, and anteriorly it is either truncated or armed with a single rudimentary rostrum. The basilary portion of the ocular peduncles is exposed. The *internal antennæ* are placed directly above these peduncles; their first joint is convex and nearly globular; the two next are delicate and cylindrical, and only go a little beyond either the peduncular portion of the external antennæ, or the eyes: the terminal stemlets of these organs are very short, and have the same form as those of the brachyurous crustaceans. The *external antennæ* are inserted on the same line as the ocular peduncles, and have, above, a stout moveable spine which represents the palp; the last joint of their peduncle is slender and cylindrical, and they are fixed by a multi-articulate filament which is very long. The *external jaw-feet* are moderate in size, their stem is pediform, and their palp very much developed. The *anterior feet* are in general very unequal, and one of the hands very convex. The fourth pair of feet are very short, and their penultimate joint, furnished above with a somewhat oval warty plate, is in general very large, and prolonged above the next joint, so as to constitute with it a didactylous pincer. The fifth pair are longer, more slender, more recurved upwards, present also towards the end a granulous plate, and are terminated by a more or less well-formed didactylous pincer. The *abdomen* is of considerable size and membranous, the plates of its dorsal rface are nearly symmetrical, but very delicate, and dis- it from each other. Sometimes there is at the base of the abdomen of the female a pair of rudimentary false feet, and two pairs of appendages more developed in the male; but in general the first segment is without any, and the second, as well as the three succeeding segments, has a single one placed on the left side, and fixed to the border of the dorsal plate. These appendages are always small, and terminated by one, two, or even three ciliated lamellæ upon their edges, which, in the female, are of considerable dimensions, and serve for the insertion of the eggs. The appendages of the penultimate ring of the abdomen are each composed of a basilary joint, which is short and stout, supporting two other short and hooked pieces, one of which is inserted at its inferior border, the other at its extremity, and each furnished with a warty plate similar to that on the posterior feet. These two false caudal feet have not exactly the same form, and are of very unequal size, that of the right side being much smaller than the other. (M. E.)

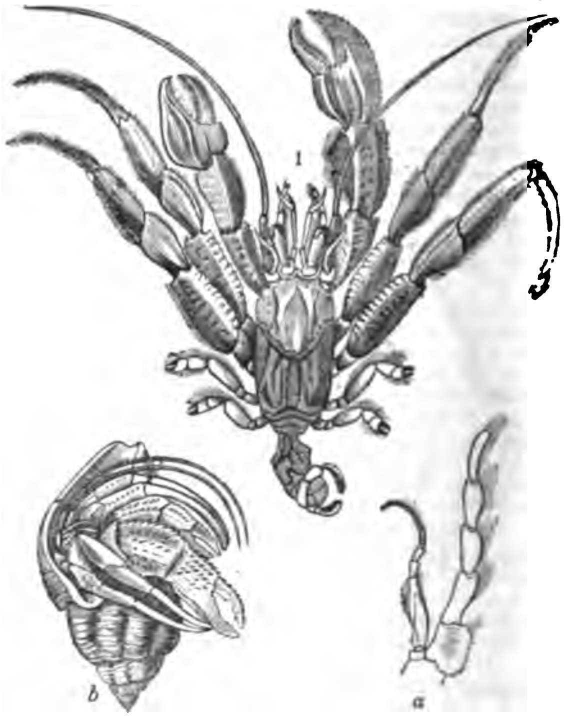
The species are numerous, and are divided by M. Milne Edwards into the following sections.

§ Species whose ophthalmic ring is not armed above with a median rostriform piece.

A. Ocular peduncles large, and shorter than the basilary portion of the external antennæ.

a. Spiniform palp of the external antennæ going beyond the extremity of the ocular peduncles.

In this section there are three species. We select the *Common Hermit-Crab, Pagurus Bernardus*, as an example.



Pagurus Bernardus.

1, out of the shell; a, right jaw-foot; b, in the shell.

Description.—Anterior border of the carapace rather deeply notched above the base of the ocular peduncles, and presenting on the median line a projecting angle which has the semblance of a small obtuse rostrum. Ocular peduncles stout, short, of the same length as the portion of the front which covers their base, and swollen, as it were, at the end. A wide space between the two basilary joints of these peduncles, which are armed with a large tooth, flattened and nearly oval, or rather lanceolate. Third joint of the internal antennæ scarcely reaching beyond the basilary portion of the external antennæ, the second joint of which is armed at its external angle with a very sharp tooth, and supports on the middle of its upper border the spiniform palp, which is very long (at least as long as the terminal joint of the ocular peduncles), slender from its base, and recurved below, then forwards, a little in the form of the letter S. Anterior feet stout, and rough with isolated, unequal, and more or less spiniform tubercles: the right much stouter than the left; carpus nearly as long as the palmary portion of the hand, which is convex above; the pincers stout, very obtuse, and without a distinct terminal nail. Second and third pair spiny and tubercular above; their the joint very small, compressed, twisted on itself and enlarged a little towards its extremity, which afterwards is rapidly narrowed to a point. Third pair separated at their base by a small sternal plastron, which is nearly square. Hands of the posterior feet very short, and terminated by a very flat and extremely short pincer. Abdomen with lateral plates only in its membranous part. In the female, four false oviferous feet, formed by a cylindrical and elongated joint, and two lamellar terminal branches. Fourth false foot much smaller than the others, and its external branch rudimentary. In the male, three false feet, composed equally of a cylindrical joint, and of two terminal pieces, one of which is lamellar and rather large; the other rudimentary; no similar appendages on the right; a semilunar notch at the posterior border of the terminal lamina of the abdomen. Ordinary length about 5 inches, sometimes more.

---

* 'Geo. Trans., vol. ii., new series.

Locality.—Coasts of England, France, and of Northern Europe as far as Iceland.

c c. Spiniform palp of the external antennæ exceeded by the ocular peduncles.

Example, *Pagurus striatus.* The anterior feet of this species are very large, especially that of the right side. They are covered nearly throughout with transverse lines, which are curved, tubercular, and furnished with small rather thick-set hairs on the upper part of the member; many of the tubercles of these squamiform lines acquire sufficiently large dimensions to become large pointed spines. Colour red mixed with yellow. Length from 7 to rather more than 8 inches.

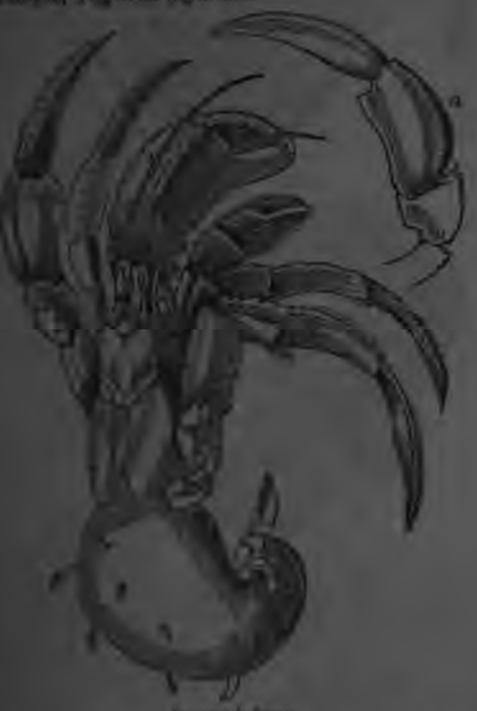
Locality.—Mediterranean sea.

Four other species belong to this subsection.

B. Ocular peduncles reaching beyond the basilary portion of the external antennæ.

b. No rostriform prolongation on the anterior border of the carapace.

Example, *Pagurus deformis.*



Pagurus deformis.

a, one of the anterior claws; the outer side of which is towards the spectator.

Description.—Ocular peduncles very stout and short, rather longer than the basilary portion of the external antennæ, but much shorter than the anterior border of the carapace; cornea large, and occupying half the length of the terminal joint of the ocular peduncles. Anterior feet short and stout, especially on one side, smooth externally, but spiny above; a denticulated crest on the upper border of the larger moveable finger. Succeeding feet smooth, and with but little hair, furnished externally with a projecting crest, which extends over the two first joints, and which, in the third foot, is very much developed and finely denticulated. Nothing similar on the opposite side. Abdomen furnished with four large transverse plates, each with an oviferous false foot; the three first of these are large, and terminated by three elongated and ciliated laminæ in the female. In the male, all these appendages are small, and terminated by a single lamina. Length 5 inches.

Locality.—The Isle of France and the Seychelles.

Six other species are arranged by M. Milne Edwards under this subsection, besides *Pagurus sanguinolentus* (Quoy and Gaim.), which he believes to be merely a variety of *Pagurus guttatus*, and not to differ from the *Pagurus Hungarus* figured by Herbst, pl. 22, f. 6.

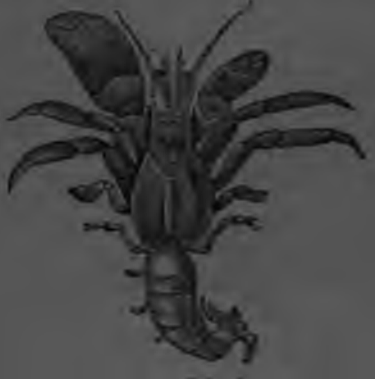
b. Anterior border of the carapace armed on the median line with a more or less projecting rostral tooth

c. No pairs of appendages on the anterior part of the abdomen.

Example, *Pagurus oculatus.* Rostriform tooth scarcely developed. Ocular peduncles shorter than the peduncular portion of the internal antennæ, but longer than the anterior border of the carapace, and with their basilary scales small, curved, nearly oval, and approximated. Anterior feet nearly symmetrical and moderate; manus spiny, and furnished with some hairs, the large fingers nearly cylindrical, and terminated by a black nail. Second and third pair nearly cylindrical, furnished with some bundles of short and scattered hairs, and terminated by a styliform tarsus much shorter than the penultimate joint. No pairs of appendages at the base of the abdomen of the male; false feet small, and four in number, with a single terminal lamella. Length two inches; colour reddish; on the tarsi are yellow and red longitudinal lines.

Locality.—Noirmoutiers. (M. E.)

Ten other species are arranged under this subsection, and *Pagurus Chilensis*, one of these, which is nearly allied to *Pagurus elegans*, and inhabits the coast of Chili, is here figured.



Pagurus Chilensis.

c c. Abdomen, with one or two pairs of appendages under its base.

Example, *Pagurus maculatus.* Rostriform tooth delicate and elongated. Ocular peduncles rather narrowed towards the middle, longer than the anterior border of the carapace, and reaching a little beyond the basilary portion of the internal antennæ. External antennæ of moderate length. Anterior feet short, thick, and finely granulated; manus convex at its base, but becoming nearly triangular towards the upper part, furnished above with a small spinous crest, and having a second crest on its lower border; fingers stout, triangular, pointed, and touching each other on a straight edge; two succeeding feet very much compressed and denticulated on their upper border; their last joint nearly lamellar, falciform, and of moderate length; penultimate joint of the fourth pair not prolonging itself much above the tarsus, which is conical and moveable. Abdomen of the male with a pair of short, stout, and lamellar appendages on its anterior and lower part; these appendages are applied against the genital orifices, and are succeeded by a second pair equally symmetrical, but slender and filiform; three false feet, terminated by a simple lamella, are fixed on the left side, as ordinarily; abdomen of the female with one pair of false rudimentary feet, applied against the base of the thoracic feet of the first pair, and followed by four ovipamous appendages, the three first of which, fixed to longitudinal and narrow laminæ, terminate by two lamellæ, and are covered by a large latero-inferior fold of the skin of the abdomen, which constitutes a concave blade, ciliated on its edge and directed forwards for the lodgement of the eggs;

the fourth filament is simple and does not appear to afford attachment to the eggs.

Locality.—The Mediterranean Sea. (M. E.)

Four other species are arranged under this subsection by M. Milne Edwards.

§§ Species having the ophthalmic ring armed above with a moveable rostriform tooth, which advances between the ocular peduncles, and is denticulated on its edges.

Example, *Pagurus Miles.*

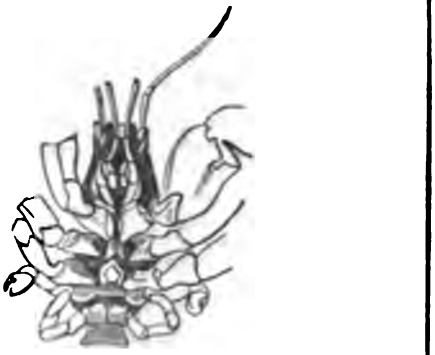
Description.—Ocular peduncles moderate, not reaching remarkably beyond the penultimate peduncular joint of the internal and external antennæ; their basilary scales large, flat, and applied against the rostriform prolongation. Anterior feet very unequal; that of the left side very strong and entirely covered above by more or less acute spines. Succeeding feet granulous and spiny above, their tarsus very long, with a trenchant edge, furrowed externally, and armed above with spines. Abdomen of the male with four rather large false feet, terminated by a long simple lamella. Length about three inches; colour yellowish.

Locality.—Coasts of India. (M. E.)

Two other species are arranged by M. Milne Edwards under this subsection.

Cenobita. (Latreille.)

This genus, in the opinion of M. Milne Edwards, establishes the passage between the *Paguri*, properly so called, and *Birgus*. The abdomen is conformable with that of *Pagurus;* the antennæ resemble those of *Birgus;* the *carapace* is equally characteristic, for it is much more solid than it is found in the *Paguri*, is narrowed and compressed forward, and presents in its posterior half a projecting border, which separates its upper surface from the lateral portion, which descends vertically towards the feet.



Under side of carapace, &c. of Cenobita.

The *ocular peduncles* are rather short, but large and compressed, so as to be nearly lamellar; the cornea occupies the terminal and external portion. The *internal antennæ*, inserted a little behind the external ones, are extremely large; their first joint, large at the base and cylindrical, reaches beyond the eyes, and has a second joint still longer; the third joint is rather longer than the second, and supports two terminal filaments, one of which is short and setiform, the other stout, rather long, and obtuse. The *external antennæ* are very much compressed, their peduncle is long, but does not reach the extremity of the second joint of the internal antennæ, and their palp is only represented by a small rudimentary tubercle. The *external jaw-feet* are pediform, short, nearly cylindrical, and devoid of teeth toward their base. The anterior feet are stout, unequal, and terminated by a short manus, which is compressed internally. (See the cut below, figure *b*.) The second and third pair are large, but present nothing remarkable; the fourth pair are nearly rudimentary, and their last joint has the form of a small tubercle, scarcely moveable; the fifth pair are formed as in *Pagurus*, except in the male, where their basilary joint presents a tubular prolongation more or less extended, at the extremity of which is the generative apparatus. The *abdomen* is membranous and rolled upon itself, as in the *Paguri*, but is shorter. In the female it has, on the left side, three rather large false oviferous feet fixed to the dorsal plates; further backward is a fourth horny plate without any appendage. At the extremity of the abdomen is a dorsal horny segment, with a median lamina on its posterior border, and on each side an appendage, that of the right side being much the smallest; the form of these appendages is the same as in the *Paguri*. In the male all these abdominal appendages, with the exception of the terminal pair, are completely wanting; but dorsal horny plates indicate the division of the abdomen into rings.

The Cenobites, which are all the inhabitants of warm climates, are thus divided by M. Milne Edwards.

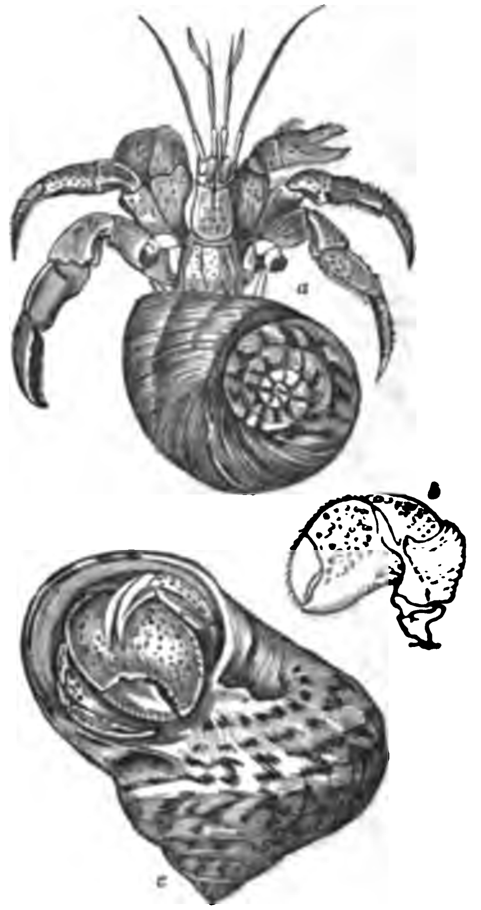
§ Species having the ocular peduncles nearly cylindrical, rounded on the upper border, and terminated by a hemispherical cornea which reaches beyond the prolongation of the peduncular joint received into the notch of its upper border.

Example, *Cenobita Diogenes.*

Description.—Stomachal region hardly convex. Ocular peduncles only of the length of the anterior border of the carapace, and nearly triangular; their basilary scale moderate and oval; tarsi very short; a trenchant and very projecting crest on the lower edge of the two last joints of the third left foot. Length about three inches; colour, especially of the large claw, red or violaceous.

Locality.—The Antilles.

Only one other species is placed by M. Milne Edwards under this section.



Cenobita Diogenes.

a, Partially out of shell, showing the arrangement and structure of the antennæ, carapace, feet, &c. Among these last, what may be called the rough-shod pair (the fourth) are well displayed; *b*, large claw (external view). (M. E.)

c, Cenobita in shell (*Turbo Pica*), showing the disposition of the first pairs of feet when the animal has retired as far as it can, and the large claw acting as a kind of operculum to protect the aperture.

§§. Species whose ocular peduncles are very much compressed, terminated above by a rather sharp border, and support a nearly triangular cornea, which does not sensibly reach beyond the prolongation of the peduncular joint received into the notch of its upper border.

Example, *Cenobita rugosa.*

Description.—Stomachal region nearly flat; labial border of the branchial regions very projecting and slightly curved. Ocular peduncles nearly twice as long as they are high; their basilary scale moderate and pointed. Feet granulous and slightly muricated; the great claw moderate, and furnished above with a row of small, oblique, and parallel crests. Tarsi short and triangular. Upper and external edges of the two last joints of the third left foot elevated into an oblique crest. Length about three inches.

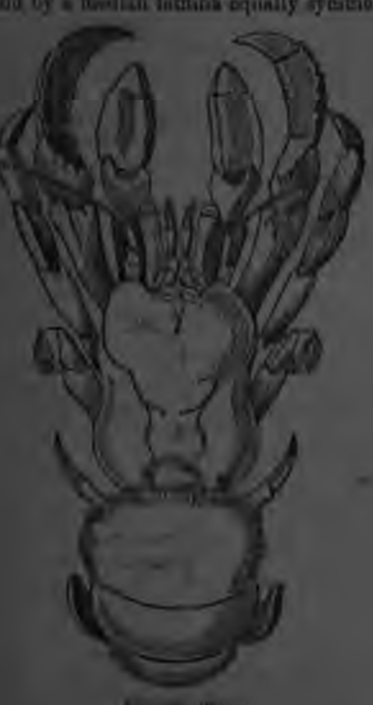
Locality.—The Indian Ocean. (M. E.)

Three other species are placed by M. Milne Edwards under this section.

Cancellus. (Edwards.)

M. Milne Edwards says of this small *generic* division, that it is but little distant from the *Paguri* properly so called, and is not as yet more than imperfectly known to him, for he had not examined the female of the only species, but the peculiarities offered by the organization of the male prevent him from referring the form to any genus already established. The *abdomen*, instead of being rolled upon itself and terminating in a sort of shapeless lobe, is perfectly symmetrical; the appendages of the penultimate abdominal ring have the same form as in the *Paguri*, but are similar on each side, and there is no other appendage adhering to the abdomen between this segment and the thorax.

Example, *Cancellus Typus*. This, the only known species, is described by M. Milne Edwards as having the rostriform tooth large, triangular, but projecting little. The anterior portion of the carapace convex and without perceptible furrows. Ocular peduncles slender, reaching beyond the peduncle of the external antennæ for nearly one-half of their length, but nevertheless shorter than the anterior border of the carapace; cornea transparent, very small, and without any notch on its superior border. External antennæ very short, hardly more than twice as long as the ocular peduncles. Anterior feet equal, and depressed above; on the upper edge of the manus a denticulated crest, which is united to a rounded longitudinal elevation on the external surface of the manus, so as to form a pyramid of three faces on the carpus; external surface of the manus a little warty; pincers very short. Second pair of feet much stouter and longer than the third, and furnished with a crest which extends from the middle of the third joint to their extremity, in describing a regular curve, the convexity of which is outwards; the upper extremity of the crest is elevated, like that of the anterior feet, pyramidically, and corresponds exactly to the extremity of the ocular peduncles, when the feet are directed forwards. Tarsi very short and rather stout. Third pair of feet very much compressed. Basilary joint of the posterior feet large and squamiform. Abdomen of the male short, large, furnished above with very narrow transverse plates, which have no appendages, and terminated by a pair of appendages as in the other Pagurians, but symmetrical, and by a median lamina equally symmetrical.



Cancellus Typus.

Birgus.

Since the article *Birgus* was written, M. Milne Edwards has published (*Histoire Naturelle des Crustacés*) some valuable observations and an elaborate description, which ought not to be omitted. This genus appears to him to establish the passage between the *Paguri* (or rather the *Cenobitæ*) and the *Lithodes*. [HOMOLIANS, vol. xii., p. 272.] Their *carapace*, terminated anteriorly by a horizontal and projecting rostrum, is divided into two portions, as in the *Cenobitæ*; the anterior portion formed by the stomachal region is narrow, but the posterior portion is very large and oval, the branchial regions being very much developed, and forming on each side a sort of semicircular buckler, which advances above the base of the feet. The *ocular peduncles* are stout, rounded, and of moderate length. The *internal antennæ* have the same conformation as in the *Cenobites*, except that their basilary joint is still more elongated. The disposition of the external antennæ and of the external jaw-feet is also entirely the same as in the last named Pagurians. The *anterior feet* are stout, rounded, and of moderate length; the two succeeding pair are terminated by a stout cylindrical joint; and the fourth pair, which are shorter than the preceding, but not elevated above them, are provided with a cheliform hand, the two fingers of which are long and cylindrical; the posterior feet, which are very short and cylindrical, are elevated under the lateral parts of the carapace, and terminated by a very obtuse rudimentary pincer. The abdomen is very large, and covered above by a small horny band, followed by four great corneo-calcareous plates, which occupy its whole width, and over-ride each other, as in the Macrurous Crustaceans. On each side of these great segments are to be seen one or two horny pieces, which seem to be the representation of the epimerian piece of the four corresponding abdominal rings. In the female, the three first of these segments, that is to say, the second, third, and fourth rings, have on each side a great false foot formed by a small basilary piece and two great narrow and ciliated appendages; these members are wanting on the right side, and in the male no trace of them is perceptible. The whole of the inferior surface of the abdomen is membranous, except that, towards its posterior part, may be seen a small quadrilateral plate, which gives attachment to a second projecting plate, and has on each side an abdominal rudimentary false foot, composed of a basilary piece and two moveable tubercles, which recal the disposition of the appendages of the sixth abdominal ring of the *Paguri*, but which is symmetrical on both sides of the body. The terminal plate is rounded at the end, covers the anus, and represents the seventh abdominal ring.

The respiratory apparatus in *Birgus* presents very remarkable peculiarities of structure. The branchiæ are fourteen in number on each side of the body, and are fixed by a peduncle situated towards the middle of their internal surface. The respiratory cavity is very large, and the branchiæ only fill the tenth part of it; its vault is carpeted below by a delicate and epidermic membrane; but this soon disappears and leaves naked the skin, which is continued with that membrane, and covered by a multitude of vascular vegetations.

For the natural history of the only species known, *Birgus Latro* (for the *Birgus laticauda*, Latr., is considered to be only the young of *Birgus Latro*), see the article BIRGUS.

FOSSIL PAGURIANS?

M. Milne Edwards is of opinion that *Pagurus Faujasii* (Desm., *Crust. Foss.*, pl. xi., f. 2) does not belong to that genus, but has much analogy with *Callianassa*. [CALLIANASSA.]

PAIMBŒUF. [LOIRE INFERIEURE.]

PAINE, THOMAS, was born on the 29th of January, 1737, at Thetford, in the county of Norfolk. His father, who was a Quaker, brought him up to his own business, that of a staymaker. At the age of twenty he removed to London, where he worked some time at his business. He then went to Sandwich in Kent, where, in 1760, he married the daughter of an exciseman, and obtained a place in the Excise, but retained it only about a year, and then became an assistant at a school in the neighbourhood of London. After leaving this situation he was again employed in the Excise, and was stationed at Lewes in Sussex. Here he had gained some reputation by various pieces of poetry, and had been selected by the excisemen of the neighbourhood to draw up 'The Case of the Officers of Excise; with Remarks on the Qualifications of Officers, and on the numerous Evils arising to the Revenue from the Insufficiency of the present Salaries,' 1772. The ability displayed in this his first prose composition induced one of the Commissioners of Excise to give him a letter of introduction to Benjamin Franklin, then in London as a deputy from the colonies of North America to the British government. Franklin advised him to go to America. He took the advice, and having settled himself at Philadelphia in 1774, became a contributor to various periodical works, and in January, 1775, editor of the 'Philadelphia Magazine.'

In January, 1776, he published in America his 'Common Sense,' which contributed in an eminent degree to make the people of that country of one mind at the time of the Declaration of Independence. Burke, in his 'Letter to the Sheriffs of Bristol,' speaks of it as 'that celebrated pamphlet which prepared the minds of the people for independence.' For this production the legislature of Pennsylvania voted him 500*l.*; the university of the same province conferred on him the degree of M.A., and he was elected a member of the American Philosophical Society. He was also made Clerk to the Committee of Foreign Affairs. During the American War he published at intervals fifteen numbers of 'The Crisis' (Philadelphia, 1776-1783), a series of political appeals intended to rouse and keep alive the public spirit.

He was obliged to resign his office of Clerk in 1779, for having divulged some official secrets in a controversy with Silas Deane, whom he accused of a fraudulent attempt to profit by his agency, in conveying the secret supplies of stores from France.

In 1781 Paine was sent to France with Colonel Lawrence to negotiate a loan, in which he was more than successful; for the French government granted a subsidy of six millions of livres to the Americans, and also became guarantee for a loan of ten millions advanced by Holland. On his return to America he was rewarded for his services by being appointed, in 1785, Clerk to the Assembly of Pennsylvania; he received from Congress a donation of 3000 dollars; and the state of New York bestowed on him the confiscated estate of Frederic Davoe, a royalist, near New Rochelle, in the state of New York, consisting of 500 acres of well-cultivated land, with a good stone house.

After the peace between Great Britain and America, Paine seems to have employed himself chiefly in mechanical speculations. In 1787 he went to France, and submitted to the Academy of Sciences at Paris a plan for the construction of iron bridges. Meeting with no encouragement, he crossed over into England, and in prosecution of his project entered into partnership with an iron-founder at Rotherham in Yorkshire, and explained the principles of his proposed construction in a letter addressed to Sir George Staunton, and printed at Rotherham in 1789. The sums which this undertaking required, together with the failure of his agent in America, involved him in difficulties, which however were only temporary.

The first part of his 'Rights of Man,' in reply to Burke's 'Reflections on the French Revolution,' was published at London, in 1791; and the second part early in 1792. An information was laid by the attorney-general against him as the author of the second part, which was designated as 'a false, scandalous, malicious, and seditious libel;' and the trial came on in the Court of King's Bench before Lord Kenyon. He was eloquently defended by Lord Erskine, then the Hon. Thomas Erskine, but the jury, without suffering the attorney-general to reply, at once pronounced him guilty. Erskine, in consequence of this defence, was dismissed from the office of attorney-general to the Prince of Wales. There are a few remarks on some of the leading principles of the 'Rights of Man' in Malthus's 'Essay on the Principle of Population,' book iv., chap. 6.

In the meantime however Paine had been chosen by the department of Calais as a member of the French National Convention, and having escaped and landed in France in September, 1792, was received with enthusiastic congratulations. He took his seat in the Convention, and when the trial of Louis XVI. came on, offended the Jacobins by voting that the king should be imprisoned during the war, and banished afterwards. He published his 'Reasons for wishing to preserve the Life of Louis Capet, as delivered to the National Convention.' Towards the end of 1793 he was excluded from the Convention as a foreigner, though he had been naturalised; and in 1794 was arrested by order of Robespierre, and committed as a prisoner to the Luxembourg.

He had finished the first part of his 'Age of Reason' just before his imprisonment: it was published at Paris under the auspices of his friend Joel Barlow. The second part was completed during his confinement; and it was published at Paris in 1795, after the author had been set at liberty on the fall of Robespierre. When the English publisher of this work was prosecuted in 1797, Erskine appeared for the prosecution, and a verdict of guilty was again pronounced. Bishop Watson's 'Apology for the Bible, in a series of Letters to Thomas Paine,' appeared in 1796.

On his liberation Paine had asserted his right to sit as a member of the Convention; and on the 8th of December, 1794, he was allowed to resume his place. About this time he gave offence to the people of America by addressing a letter to General Washington, in which he reviled him for not interfering to procure his liberation. In the course of 1795 he published at Paris 'A Dissertation on the First Principles of Government;' 'The Decline and Fall of the English System of Finance;' and 'Agrarian Justice opposed to Agrarian Law and to Agrarian Monopoly: being a Plan for meliorating the Condition of Man, by creating in every Nation a National Fund to pay to every Person, when arrived at the age of twenty-one years, the sum of fifteen pounds sterling, to enable him or her to begin the World; and also ten pounds sterling per annum during Life, to every Person now living of the age of fifty years, and to all others when they arrive at that age, to enable them to live an old age without wretchedness, and go decently out of the World.' We give the full title of this Utopian tract as a curiosity. The fund was to be created by taking, on the death of every individual, 10 per cent. of his property, as 'due to society,' and from 5 to 12 per cent. more if there were no near relations, in proportion as the next of kin was nearer or more remote. He states that this little piece was written in the winter of 1795-6.

Paine remained in France some years longer, but having written to Mr. Jefferson, who had recently been elected President of the United States, and expressed a wish to be brought back to America in a government ship, Jefferson wrote to him, and offered him a passage in the Maryland sloop of war, which he had sent to France for a special purpose. In his letter, dated March, 1801, Jefferson expresses his high estimate of Paine's services in the cause of American independence in the following words:—'I am in hopes you will find us returned generally to sentiments worthy of former times. In these it will be your glory to have steadily laboured, and with as much effect as any man living. That you may long live to continue your useful labours, and to reap their reward in the thankfulness of nations, is my sincere prayer.'

Paine did not embark for America however till August, 1802; he reached Baltimore in the following October. His first wife had died about a year after their marriage; he lived about three years with his second, whom he married soon after the death of his first, when they separated by mutual consent. During his last residence in France he had become intimate with Madame Bonneville, the wife of a French bookseller, who, with her two sons, accompanied him to America. After his return he published four or five treatises on iron bridges, the yellow fever, on the building of ships of war, &c.

He died on the 8th of June, 1809, and was buried in a field on his own estate near New Rochelle. Cobbett, some eight or nine years afterwards, disinterred his bones and brought them to England; but instead of arousing, as he expected, the enthusiasm of the republican party in this country, he only drew upon himself universal contempt. Paine bequeathed his estate and the chief part of the rest of his property to Madame Bonneville, conjointly with her husband and her two sons.

Paine, from his first starting in public life, was a republican, uniformly consistent and apparently sincere. His style is vigorous and clear, but somewhat coarse; though simple, it is enlivened with comparisons and illustrations which render it very popular and attractive. He saw clearly the weak points of any object against which he directed his attack, and accordingly he was a vigorous assailant; but he was not qualified, either by competent knowledge or by habits of patient investigation, for examining any subject in all its bearings. His merits may be briefly summed up: he was a bold original thinker, who exercised a very considerable influence on the political and religious opinions of his day, and that influence is not yet gone. What he saw and felt, he expressed clearly and forcibly. In his 'Age of Reason' he shocked the religious feeling of all

Christians by the grossness and scurrility of his language, without always convincing those who were well inclined to listen to his arguments. Such difficulties as really do exist in the gospel history could not escape his acuteness; but for want of moral knowledge he sometimes exposes himself when he thinks that he is exposing the sacred writers. The work alienated from him his friends in America, as well as in England, excited feelings of the deepest disgust and abhorrence in the whole Christian community of both countries, and exposed him to hatred and insult and calumny to such a degree as to embitter the latter years of his life, and probably to increase, if they did not produce, those habits of intemperance with which he was truly and justly charged.

PAINSWICK. [GLOUCESTERSHIRE.]

PAINTER'S COLIC, called also Devonshire colic, and colica Pictonum, from its former frequency in those parts, is a peculiar and well known variety of colic, to which lead miners, painters, and others who use that metal are subject. The symptoms are, severe pain in the belly, with obstinate constipation and occasional vomiting, which is generally followed by partial palsy, and in violent cases by apoplexy. The palsy usually affects the upper extremities, so that the arms hang powerless by the sides, the extensor muscles being the most impaired. Emaciation and paleness of the muscles affected are of very frequent occurrence.

'A first attack taken under timely management is for the most part easily made to terminate favourably. In such circumstances it rarely endures beyond eight days. But it is exceedingly apt to recur, especially if the patient return to a trade which exposes him again to the poison of lead. Sometimes the primary stage of colic is wanting, so that the wasting of the muscles and loss of power are the first symptoms.' (Christison.)

The principles to be observed in the treatment are, to remove the pain and constipation, and to obviate or lessen the remote effects. In first attacks it is not very difficult to effect the former object, but with every succeeding attack these symptoms are found more obstinate. Inflammation is rarely a primary symptom, but may ensue as in other kinds of colic. Want of power in some portion of the bowel, by which it becomes distended, and excessive contraction of another portion, are the usual conditions.

By saline purgatives, such as sulphate of magnesia, sulphate of alumina and potass, or phosphate of soda in solution, followed shortly by a large dose of opium, the constipation may be removed in the milder cases. To counteract the occurrence of inflammation, calomel and opium are preferable mostly to bleeding, in a disease where debility is one of the usual consequences. The constipation has been known to last for a month. In such a case it was customary to give the patient three or four pounds of crude mercury, in the hope that by its mechanical properties it would force a passage. Nothing is more reprehensible, as it irritates the contracted part of the bowel, and distends yet further the enfeebled and dilated part. Most cases of constipation will yield to pills of aloes and sulphuric acid, in the proportion of one drop of strong sulphuric acid to four grains of powdered aloes. Two of these pills every four or two hours will speedily remove this state.

The paralysed arms must be supported by splints. It is however of little use to cure a first attack, if the sufferer be immediately the subject of a second, which he certainly will be without the greatest care. Should he be unable to change his employment, he must be very strict in the observance of the following rules: he should never eat without first thoroughly washing the hands and face; and never take his meals in the workshop. 'Yet it is the common practice of the smelters of lead,' says Dr. Percival, 'and others also who live in the neighbourhood of smelting-mills, to broil mutton, beef, and pork steaks on the hot pigs of lead, by which the flesh acquires a peculiar agreeable flavour.' When leaving work, a different suit of clothes should be put on, and when baths are attached to the manufactory, a complete immersion in them after work, is advisable. The miners of Alston Moor derive great benefit from the saline mineral waters of [illegible] Holywell, to which they annually repair. Here, besides the chemical constitution of the waters being appropriate, an action on the bowels is ensured, and it is observed that an open state of bowels is always a great protection. On this account many masters keep a supply of castor oil on the premises, to which the workmen have free access. Fat and oily food is likewise a great safeguard. Sobriety is still more effective as a safeguard, for it is observed that among miners, potters, and all persons working among lead, drunkards suffer soonest and most severely. In all cases where the dust of the lead can be kept down by watering, this should be done, as it proves a very valuable means of exemption. Wherever it is practicable, other more innocent articles should be substituted for lead, in the various manufactures where it is now used. (Christison *On Poisons*; and Thackrah *On the Effects of Arts, Trades, and Professions*.)

PAINTING is that art of design which imitates objects by colour on a uniform surface.

As compared with sculpture, it is more extensive in the range of subjects which it is capable of treating, and more various in the modes in which it affords pleasure by such representation. Those subjects are fitted for sculpture which are sufficiently defined by form alone without the aid of colour, and which tell their story and possess unity without accessories, or, at any rate, need only accessories so few and so simple, as to be within the reach of the chisel.

The landscape or the subordinate circumstances can at best be only hinted at in sculpture; whereas in painting they are easily represented, and while they illustrate the story, enhance the effect of the picture. Simple form and character in a state of repose are the most favourable qualities for the sculptor; but passion and transient emotion, together with the external circumstances which excite them, are equally attainable by the painter. The former produces pleasure mainly by beauty of form; the latter works on the eye by the joint effect of form, light and shade, and colour.

In Egypt, painting seems to have originated in the colouring of bas-reliefs and statues: for the most part, when laid on a flat surface, the colour is free from shadow, and consists of the mere local tint, which is often conventional. The paintings executed on the walls of their tombs represent subjects of every class—battles, triumphal processions, scenes of agriculture and domestic life. A very good specimen of the latter class may be seen in the British Museum, representing a banquet. The wooden cases of the mummies are remarkable for the brilliancy of their colours. Homer, though he mentions garments elaborately embroidered or woven with figures, speaks of nothing nearer akin to painting than the colouring of the ships or the staining of ivory by a Carian woman. The origin of the art is ascribed to Corinth or Sicyon; but the name of its supposed inventor, as recorded by Pliny, is evidently deserving of little attention. Cleanthes of Corinth is said to have made the first outline; Ardices, of the same city, and Telephanes of Sicyon, to have introduced some lines within the figure; and Cleophantus to have coloured it with a single colour, and thus produced 'monochromata.' The legend of Cleophantus, or Eucheir and Eugrammus, having accompanied Demaratus from Corinth to Italy (Olymp. 30, B.C. 657), probably points to the early connection of Greek and Italian art, or to the taste for the former which existed in Etruria and the neighbouring countries, as is sufficiently attested by the innumerable vases with Greek stories and Greek inscriptions now found in Italy. The grotesqueness and clumsiness of the figures on the earlier vases, and their progressive improvement, show how little ground there is for the notion that the proportions of the human figure in early Greek art were fixed by some type derived from Egypt or elsewhere, instead of gradually developing themselves as the culture of the race advanced.

The very curious paintings on the walls of the Etruscan tombs should here be mentioned; and Pliny speaks of antient works existing in his time in a temple at Ardea, as well as at Caere and Lanuvium.

Between the 50th and 60th Olympiad (from B.C. 580 to 540) painting advanced considerably in Greece.

Historical pictures of very early events are recorded, one indeed by Bularchus, in the reign of Candaules, who died Ol. 16. 1, B.C. 716. Cimon of Cleonae invented 'catagrapha,' that is, figures seen obliquely from above or below, and thus applied the rules of perspective. The peculiarities of drawing of this early period are best learned from the study of the antient vases; the forms and protuberance of the muscles are exaggerated, and the positions strained and unnatural.

Polygnotus of Thasos, who probably settled at Athens about Ol. 79. 2 (B.C. 463), was the first painter of great excellence, and the founder of what may be called the

Athenian school. Aristotle (*Poet.*, vi.) calls him ἀγαθὸς ἠθογράφος, 'successful in his expression of character;' and Pliny speaks of him as having abandoned the old stiffness, and having given movement to the features—'instituit os adaperire, dentes ostendere, vultum ab antiquo rigore variare.' His transparent drapery is also mentioned. Pausanias (x., 25-31) describes his pictures in the Lesche at Delphi—the Capture of Troy, the Departure of the Greeks, and Descent of Ulysses to the Shades. In the Pœcile at Athens his works stood by the side of the Battle of Marathon by Panænus, the nephew or brother of Phidias, and of the Combat between the Athenians and the Amazons by Micon. This latter artist, together with Onatas of Ægina and Dionysius of Colophon, were the most celebrated contemporaries of Polygnotus.

The principles of light and shade were investigated by Apollodorus of Athens about the 94 Ol. (B.C. 404). To the school of Athens succeeded what may be termed that of Ionia, in which illusion seems to have been more aimed at. This we may infer from the well-known story of the grapes of Zeuxis and the linen cloth of Parrhasius. The former, with whom begins the second epoch of the more advanced art, was of Heraclea, and flourished about Ol. 94. (B.C. 404). His excellence seems to have been equally conspicuous in female beauty (as the Helen of Crotona), and the sublimity of Jupiter and his attendant gods.

Parrhasius was of Ephesus, and he is no less celebrated for the roundness and relief of his figures than for their exquisite form and expression. His contemporary Timanthes overcame him in one of those contests between painters which were not unfrequent in Greece, and are said to have been first instituted at Delphi in the time of Panænus. Among the antient paintings from Pompeii is one of the same subject (the Sacrifice of Iphigenia) as that of Timanthes, mentioned in Pliny, and in which the grief of the father is represented in the same way by the concealment of the face.

Another school arose at Sicyon, in which the most celebrated names were—Euphranor of Corinth (Ol. 104-110, B.C. 364-340), Pausias of Sicyon (Ol. 103, B.C. 368), Aristeides of Thebes (Ol. 102-112, B.C. 372-332), and Pamphilus of Amphipolis (Ol. 97-107, B.C. 392-352). The first of these, a sculptor as well as a painter, was laborious and consistently excellent in all that he undertook. Aristeides was remarkable for his expression of passion; Pausias practised encaustic painting with great success, having acquired the art from Pamphilus. Pliny enumerates three modes of encaustic painting—1st, without wax, with a hot point on ivory; 2nd, that in which the colours combined with wax were laid on with a stylus and burnt in; 3rd, the mode adopted for painting ships: but it is almost impossible for us to form any distinct notion of the process pursued in the two last. Pausias was noted for his children and lighter subjects, and first decorated roofs and arches with figures. Pamphilus succeeded in establishing a knowledge of the rudiments of drawing as part of a liberal education. He was moreover the teacher of Apelles, who united the softness and colouring of Ionia with the science of the Sicyonian school. His excellence in female beauty was attested by the Venus Anadyomene at Cos; his power in sublime subjects and his technical skill, by the Alexander wielding the Thunder at Ephesus. The liberality of Apelles first brought into notice a rival of his fame, Protogenes of Rhodes, or rather of Caunus in Caria. This artist excelled in a laborious study of nature, and Apelles declared that his own superiority over Protogenes consisted in his knowing when to take his hand off. They both executed numerous portraits, and Apelles was honoured with the exclusive privilege of painting Alexander the Great. Nicomachus probably preceded Apelles; he seems to have rivalled Luca Giordano in quickness of execution. Nicias of Athens, Theon of Samos, and Melanthius were contemporaries of Alexander. The first of the three was excellent in light and shade, and painted battles and historical subjects on a large scale.

The antients possessed also their painters of low and domestic subjects, their rhyparographi, of whom Pliny names Pyreicus, Calades, and Antiphilus.

At Rome, C. Fabius Pictor is said to have derived his name from decorating the temple of Health (A.U.C. 450, B.C. 304). The poet Pacuvius (B.C. 219-140) was an artist. The victory of L. Scipio over Antiochus (B.C. 190) was recorded by a picture in the Capitol, as that of M. Valerius Messala over Hiero had been by an historical painting in the Curia Hostilia (B.C. 264). The first foreign picture publicly exhibited at Rome was after the sack of Corinth by Mummius (B.C. 146), an event which brought many of the finest works of art to the conquering city, however little the victors were qualified to appreciate their real worth.

At a later period we hear of Arellius, Amulius, Accius Priscus, and Ludius, of whom the last, in the time of Augustus, painted landscapes, garden scenes, and buildings on the walls of rooms, such as we see in the ruins of Pompeii or the remains of the palace of Nero. Cæsar purchased the 'Ajax' and the 'Medea' of Timomachus for 80 talents, and at his time a school of some eminence existed at Cyzicus. The forced bloom of art which characterises the age of Hadrian implied a momentary revival of painting, and Aetion (of whom Lucian speaks so highly) must probably be reckoned as his contemporary.

It remains to say something of the general qualities of antient painting and the materials used by them. The painting of antient Greece remained dependent on architecture for a longer period than sculpture, and it seems always to have been strongly influenced by the latter art. Thus for the most part the composition of antient pictures was simple, and resembled the order of a bas-relief. A good instance of this is the well-known Aldobrandini Marriage. The figures stand separately: 'Spatiis distinguunt ne umbræ in corpora cadant.' (Quintilian, *Inst.*, viii., 5, 26.) The light was uniform, and free from those strong effects of chiaroscuro visible in many modern works; violent foreshortening was avoided. These seem to have been the *general* characteristics of antient painting, but there are exceptions to all of them. Perhaps the most remarkable one extant is the complicated and picturesque composition of the mosaic lately discovered at Pompeii, representing the battle of Issus, and probably copied from some celebrated picture. After all, the few specimens rescued from the ruins of a small provincial town cannot be expected to give us much notion of the colouring or execution of the antient masters; what their drawing must have been we are well able to judge from the vases. They studied the principles of harmony and relative proportion of colours (harmoge), as well as the general force and effect of light and shade (τόνος, splendor), which Apelles promoted by a glazing or varnish peculiar to himself.

The four colours which were the basis of the colouring of the antients down to the time of Apelles were—1, white, Melian earth, or, more rarely, cerussa, white lead; 2, red, rubrica from Cappadocia, called sinopis; 3, yellow, sil, ὤχρα, from the Attic silver-mines; 4, blacks (probably including blues), atramenta, μέλαν, from burnt plants or ivory. These were the '*colores austeri*,' to which were afterwards added the brighter and more expensive colours, 'floridi,' which were usually furnished to the painter by his employer. Vermilion (cinnabar) was called minium by the antients; what we call minium (red lead) was by them termed 'cerussa usta.'

The following is a short summary of the experiments of Sir H. Davy on antient colours from the walls of the baths of Titus and of Livia, and from other ruins at Rome and Pompeii. Some vases were also found beneath the palace of Titus containing colour, and in one of them were three kinds of red, one red-lead and the other two ochres. The yellows were ochres varied by mixing with chalk and yellow oxide of lead, 'massicot.' Orpiment (sulphuret of arsenic) is mentioned by Pliny and Vitruvius under the name of σανδαράκη, but none was found by Davy. All the blues analysed consisted of the blue frit of soda, silica, and oxide of copper invented in Egypt and made at Pozzuoli. Pliny and Vitruvius speak of Indian blue supposed to have been indigo, but none was found. The greens proved to be carbonate of copper, and in one case the green earth of Verona. No traces of the shell purple were found on the walls, but some is supposed to have been discovered in an altered state in a broken vase. The blacks agreed with the description of the antients, as being the charcoal or soot of resins. The browns were oxide of iron or ochres, or a mixture of oxide of iron and manganese. No 'cerussa' was discovered, but the whites were either carbonate of lime or fine white clay. The ground on which the colours were applied agreed with that described by Vitruvius, and consisted of powdered marble, cemented with lime, and highly polished. No traces of *wax* as used by encaustic painters were found by Davy.

Italian Schools.—The earliest professors of Christianity appear to have abstained from the use of images and the practice of the arts, bound up as they were with the abominations of heathen worship. Very little trace of Christian art is discernible before the time of Constantine, when the new religion became dominant, and could appropriate to her own purposes those means of affecting the imagination which had hitherto so effectually served her rival.

We do not of course trace that gradual attempt to improve the technical part of the arts of design which is visible among the Greeks and in the middle ages. The Christians found the shell of antient art yet remaining; the traditionary handicraft existed, but the spirit which had enlivened it was fled.

In the very early Christian works a certain tendency to symbolism and allegory is peculiarly visible. The first representation of Christ is in the character of the good shepherd as mentioned by Tertullian (*De Pudicitiâ*, cap. 10). The walls of the catacombs of Rome and Naples displayed stories from the Old Testament as types of Christ in far greater number than direct representations of scenes from the New. The subject of Orpheus was not uncommon, apparently with some mystical reference to Christianity.

St. Augustin, in the latter half of the fourth century, speaks of the sacrifice of Isaac as a common subject, 'tot locis pictum,' (*Cont. Faustum*, xxii. 73), and refers to the representation of St. Peter and St. Paul accompanying our Lord (*De Consensu Evangel.*, i. 10). Some of the most interesting remains of early art are to be found in illuminated MSS. and in mosaics. Of the former class the most remarkable is a MS. of the Book of Joshua in the Vatican Library. The execution of these miniatures is said to be very good, while the costume and the representation of towns and rivers by the personifications familiar to the ancients argues the high antiquity of the designs.

In the fifth century, the erection of sumptuous basilicas gave occasion for a great display of mosaic. In heathen times the images of the Cæsars, the only objects of universal adoration throughout the Roman world, had been placed in the tribune of these buildings; and when they were adapted to Christian worship, the colossal figure of Christ with his apostles was usually displayed on the half cupola above the altar. These representations of the Saviour and his apostles, especially St. Peter and St. Paul, bear marks of that type which may be traced back to a very early period, and which in after-times became the groundwork of the highest dignity and beauty without losing its peculiar character. Their costume is generally more or less antique, consisting of the tunic and the pallium, with sandals.

At Byzantium, the empty form of art, as of everything else, continued in all its pomp. Great mechanical skill in the use of gilding, joined to an anxious and spiritless imitation of older forms misunderstood, long continued to characterise this school, from which the church paintings of the modern Russians and Greeks are directly derived.

The Ostrogoth dominion was not unfavourable to art; at least there is a studied affectation of classical knowledge in Cassiodorus, and the mutilators of antient statues are denounced as criminals. The Lombards could have brought no art with them, and were unlikely to appreciate what they found. The most remarkable monument of their time is the large MS. of the Bible from Monte Amiata, still preserved in the Laurentian Library at Florence. The union of the church with the Frank empire gave the popes greater leisure and means, and Rome became once more a capital.

It is probable that the conquest of Constantinople by the Latins in 1204 supplied to the Italians some of that technical skill which the wild conflicts of their own parties at home had contributed to obliterate. This event was followed in a short time by the rise of the school of Siena, which has scarcely received the notice due to its early merit, owing to the fact that the history of art has been written principally by favourers of Florence.

The magnificence of the latter city replaced that of the former when the Ghibelline interest was crushed by the fall of the house of Hohenstaufen.

In San Domenico of Siena is a picture, by Guido of that city, with the date of 1221. The face of the Virgin shows traces of the type which afterwards characterised the Sienese school. Nearly contemporary with this painting were the works of Giunta of Pisa, and probably those in the Baptistery of Parma. Cimabue was born at Florence (according to Vasari, in 1240); his great picture in Santa Maria Novella is conceived with grandeur, and shows marks of the struggle then about to be made in painting. The frescoes at Assisi are particularly important for this period of the history of art.

The next great name which requires notice is that of Giotto di Bondone, born near Florence in 1276 (d. 1336). He is mentioned by Dante (*Purgat.*, xi. 94) as supplanting Cimabue in the estimation of his countrymen. What Giotto really did in art has often been mistaken. Instead of adhering religiously to the old type in sacred subjects, he directed attention more to real life, and gave to the Florentine school the practical tendency which suited the active and commercial spirit of that great republic, and which remained for a long time characteristic of the masters who followed him. It is probable too that he replaced the thick and dark-toned vehicle used by the Greeks by some more colourless medium resembling that of the early Italians; perhaps the yolk of egg and juice of young fig shoots, which is mentioned by Vasari and by Cennino Cennini, but by the former ascribed to the Byzantines. The only picture remaining which bears Giotto's name on it is that in Santa Croce. The cast of his faces is singular: the eyes are long, narrow, and placed near together; the nose of a peculiar form, and the chin projecting and angular. The most important works for the history of the Florentine school immediately after the time of Giotto are—The life of the Virgin, in the Baroncelli chapel in Santa Croce, and a portion of the paintings in the Spanish chapel of Santa Maria Novella, by Taddeo di Gaddi (b. about 1300), the godson and pupil of Giotto; some frescoes also of the life of the Virgin, by Angelo Gaddi, son of the former artist, in the cathedral of Prato; and the works of Andrea di Cione (or Orgagna, d. 1389), at once a painter, sculptor, and architect, in the Campo Santo at Pisa and in Santa Maria Novella. At Siena, Duccio di Buoninsegna contracted, in 1308, to paint the remarkable picture still hanging up in the cathedral of that city. It consists of a number of small compartments representing the life of Christ, and gives a high idea of the artist's powers of imagination and composition. Simone di Martino, whom Vasari calls Simone Memmi, and ranks among the pupils of Giotto, is by Petrarch spoken of as the rival of that master's fame, and no such connection as that of master and scholar is alluded to by Ghiberti. Lippo di Memmi worked in concert with Simone, and a joint picture with their names and the date of 1332 is to be seen in the gallery of Florence. The works of Ambrogio di Lorenzo, Taddeo di Bartolo, and others, in the palace and academy of Siena, enable us to judge of the excellence of that school at the end of the fourteenth century. Its characteristics were an adherence to old types and forms, more rigid than was practised by their Florentine contemporaries; a darker colouring in the flesh and a form of face best characterised by being contrary in every particular to that adopted in the old Cologne school—the nose is straight and disproportionately long, the forehead low, the eyes half closed and lengthened out, and the whole face oval.

At the beginning of the fifteenth century a fresh impulse was given to Florentine art, through the advances made in sculpture by Lorenzo Ghiberti (b. 1378, d. 1455), Donatello (b. 1383, d. 1466), and Luca della Robbia (b. 1388, according to Vasari). The groundwork was thus secured for profiting by the genius of the two great men, Fra Angelico da Fiesole (b. 1389, d. 1455) and Masaccio (b. 1401, d. 1443), who supplied respectively the finest feeling for the gentle and devotional affections, and a power of drawing and composition, joined with the requisite relief by light and shade. The best works of the former are to be seen in the Academia and the Gallery at Florence, and in his own convent of St. Mark in that city. A picture of great excellence from St. Domenico at Fiesole is in the Louvre. Masaccio's frescoes, jointly with those of his master Masolino and of Filippino Lippi, decorate the Brancacci chapel in the Carmelite church at Florence.

The school of Florence now produced masters of first-rate excellence, of whom the following were the principal:—Filippo Lippi (b. 1412, d. 1469), painted, besides many smaller pictures, the frescoes in the choir of the cathedral of Prato. Alessandro Filipepi, commonly called Sandro Botticelli (b. 1437, d. 1515), executed some works in the Sistine Chapel. The features of his females are in general far from beautiful, though there are exceptions, as in the picture of the Crowning of the Virgin in the Florence Gallery. Filippino Lippi was the son of Filippo Lippi (b. 1460, d. 1505). His powers may be judged of by his frescoes in

Santa Maria Novella, and by a most exquisite Virgin in a tabernacle in the open street at Prato, which, when we saw it (1834), was not even kept locked. Cosimo Roselli also worked in the Sistine Chapel, but his happiest production is a fresco in the church of St. Ambrogio at Florence, painted in 1456.

Benozzo Gozzoli was a scholar of Fra Angelico, and inherited his expression of the gentler feelings and his light clear carnations. He was moreover the first painter who delighted much in landscape and its accompaniments, a quality most remarkable in his works in the Campo Santo (painted 1469-85).

Domenico Corradi, the master of Michael Angelo, surnamed Ghirlandaio (b. 1451, d. 1495), executed some most beautiful frescoes in the Capella Sassetti in Santa Trinità at Florence and in Santa Maria Novella. He was employed too in the Sistine Chapel.

The three masters who carried the study of the naked form (hitherto but imperfect) to the highest point, towards the end of the fifteenth century, were Andrea del Castagno (d. 1480), known for the tragical story of the assassination of Domenico Veneziano after obtaining from him Van Eyck's secret; Ant. del Pollajuolo (b. 1426, d. 1498); and Verocchio (b. 1432, d. 1488): both the latter were better sculptors than painters.

All the progress of what may be called the executive part of painting, amid the bustle of a prosperous city like Florence, implies some sacrifice of the higher and purer feeling, such as had characterised the school of Siena and had attained perfection in the works of Fra Angelico.

The seeds of that devotional simplicity which were afterwards destined to unite with the greatest technical excellence in the works of Raphael, seem to have sprung up in Umbria. In this district the enthusiastic tone of the order of St. Francis and the prolonged influence of some of the Sienese masters probably paved the way for the feeling which pervades the works of Pietro Vanucci della Pieve, or Pietro Perugino, as he is commonly called (b. 1446, d. 1524). Of his education little is known: in his 25th year he visited Florence, then Rome, and finally opened a school at Perugia about the end of the fifteenth century. His earlier works are those which possess most of his characteristic merits—such as that in the Palazzo Albani, painted 1480. The Dead Christ however, painted for the nuns of Santa Chiara, in 1495, and now in the Pitti Palace, is most beautiful. The frescoes in the Collegio del Cambio at Perugia were executed in 1500.

At Bologna, Francesco Raibolini or Francia (d. 1533) painted very much on the principles of Perugino, and rivalled the simplicity and purity of the Umbrian school. In his later years he became a correspondent of Raphael and was influenced in his style by that master. Giacomo Francia imitated his father; but the most eminent pupil of Francesco was Lorenzo Costa of Ferrara. At Padua, Francesco Squarcione (b. 1394, d. 1474) and his scholar Andrea Mantegna (b. 1431, d. 1506) formed a peculiar style on the study of the antique. There is almost more of the bas-relief in their drapery and composition than is compatible with painting, and a fantastic application of antient sculpture and architecture characterises the accessories of their pictures. Mantegna's principal works are his frescoes at Mantua, his cartoons of the Triumph of Cæsar (now at Hampton Court), an altar-piece in the Louvre, and another in St. Zeno at Verona. An offshoot of the Paduan school took root at Ferrara, and to it belonged Cosimo Tura, Lorenzo Costa, and Ercole Grandi. At Naples a school had also arisen, but its works are little known. Venice gave early promise of her future greatness, and the tendency to brilliant colour was very soon visible in her artists. One family of Murano, towards the end of the fifteenth century, produced Antonio, Bartolomeo, and Luigi Vivarini. To Carlo Crivelli and Antonello da Messina (who is said to have imported into Italy the practice, if not the secret, of oil-painting) must be added the chief of the old Venetian school, Giovanni Bellini (b. 1426, d. 1516). His exquisite pictures may take their place by the side of those of Perugino: they are characterised by simple composition, pure feeling, fine full forms, and a brilliancy of colour worthy of the master of Titian. His elder brother, Gentile Bellini, who visited Constantinople (b. 1421, d. 1501), and several other masters of the school, deserve mention, particularly Marco Basaiti, Vittore Carpaccio, and Cima da Conegliano.

We have now brought up our account of Italian painting to the end of the fifteenth century, when, from the schools of Ghirlandaio, of Verocchio, of Perugino, and of Bellini, were bursting forth M. Angelo, Leonardo da Vinci, Raphael, Giorgione, and Titian. As the lives of these painters have a place under their respective names, we shall briefly touch here on their position with reference to the general history of art. Leonardo da Vinci was born in 1452, and died the year before Raphael, 1519. In the eagerness with which he explored the anatomical and scientific groundwork of his art, he anticipated M. Angelo, as he rivalled him in the varied application of his genius. It is in Leonardo that we first recognise a thorough feeling for the roundness of objects, and a greater breadth and simplicity in the masses of light and shade.

If it be true that Pietro Perugino studied in the school of Verocchio, Leonardo may have gained from him the pensive and gentle conception of sacred subjects which he combined with so exquisite a sense for beauty of form. In conjunction with Leonardo must be mentioned his fellow-pupil Lorenzo da Credi (d. 1530), who imitated his style, and painted with great tenderness and purity of feeling. Bernardino Luini (painted in 1530) has left at Milan and elsewhere many works which have been ascribed to his master. He was in every respect the most successful imitator of Leonardo. M. Angelo Buonarotti (b. 1474, d. 1563) was at once painter, sculptor, architect, poet, and musician. Educated in the school of Ghirlandaio, he attained, by twelve years' study, a thorough knowledge of the human form. His first work as a painter which attracted notice was the cartoon of the War of Pisa, executed in rivalry with Leonardo. In the frescoes of the Sistine Chapel simple grandeur characterises the prophets and sibyls: less austere beauty is visible in some of the compartments of the ceiling, and the whole is such a work as could only have been produced by the union of a painter and architect. The Last Judgment displays the greatest power, but must be admitted to want a true Christian character. The God of M. Angelo is a God of wrath, and the stern feeling of the Old Testament pervades his works. He executed very few cabinet pictures; perhapsn one that can be authenticated, except the Holy Family 'à tempera,' in the Tribune at Florence. His pupil Marcello Venusti (b. 1515, d. 1576) painted from drawings of his master, and the designs of M. Angelo supplied the groundwork for some of the pictures of Sebastian del Piombo; probably, among others, for the Raising of Lazarus, now in the National Gallery, London. His most independent pupil was Daniele Ricciarelli, or Daniele da Volterra (b. 1509, d. 1566), whose best work is the Descent from the Cross in Santa Trinità dei Monti.

Contemporary with these masters must be mentioned Baccio della Porta (b. 1469, d. 1517), commonly called Fra Bartolomeo, a Dominican monk, and the friend of Savonarola. Educated in the school of Cosimo Roselli, he appears to have profited by the works of Leonardo. His pictures are rare out of Italy: they show fine devotional feeling, rich mellow colouring, and dignity of form. The best are to be seen in the church of San Romano at Lucca and in the Pitti palace.

Andrea Vanucchi, commonly called Andrea del Sarto (b. 1488, d. 1530), was originally a pupil of Pier di Cosimo. Among his earliest works are the frescoes in the court of the Scalzo, and among his best, those in that of the Annunziata, both at Florence. His easel pictures are not uncommon; a very good and late one is the Sacrifice of Isaac, at Dresden. His forms have great breadth and simplicity. In 1518 Andrea visited France, but destroyed his own character by returning to Italy in the following year and misapplying money belonging to Francis I. M. Antonio Franciabigio and Jacopo Carucci (called Pontormo) imitated Andrea del Sarto.

Raphael Sanzio of Urbino was the son of Giovanni Sanzio, himself a painter. He was born in 1483 and died in 1520. No master ever rivalled the tenderness and sweetness of his female forms or surpassed the power shown in his larger works. The difference between his best pictures and those of other painters is one of kind rather than of degree, and the quantity which he produced in a short life is as remarkable as the fact that scarcely one of his works can be called ordinary in expression or careless in execution. In his Madonnas he enhanced the simple beauty and pure feeling of the Umbrian school. In his frescoes he rivalled the grandeur of Buonarotti, and in his portraits he surpassed the truth and individuality of Titian or Vandyke.

The pupils of Raphael were numerous, and the dispersion which followed the sack of Rome by the Imperialists in 1527, spread their works and influence far and wide throughout Italy. Giulio Pippi, or Giulio Romano (b. 1492, d. 1546), was the most celebrated of Raphael's scholars. He had executed a portion of the frescoes in the Vatican from his master's designs. After his death he executed some very remarkable ones of his own, at Mantua, particularly those representing the Fall of the Giants. His altar-piece in S. Stefano at Genoa is a very fine work. His forms are ambitious, but he wanted the pure grace of Raphael, and in his oil pictures the tone of his shadows in the flesh is more violet. Francesco Primaticcio (b. 1490, d. 1570), who painted much in France, was a pupil of Giulio. Giovanni da Udine (d. 1564) was Raphael's principal assistant in the execution of the fruits, flowers, and other objects in the arabesques of the Loggie. Pierino Buonaccorsi, or Perino del Vaga (b. 1500, d. 1547), painted at Genoa; and Gian Francesco Penni, surnamed Il Fattore (b. 1488, d. 1528), carried the principles of Raphael's school to Naples. Timoteo della Vite of Urbino (b. 1470, d. 1524), and Bartolomeo Ramenghi, or Il Bagnacavallo, came from the school of F. Francia to that of Raphael, and the latter returned to Bologna. Benvenuto Tisio, surnamed Garofalo (b. 1481, d. 1559), came from Ferrara, and carried back thither what he had acquired at Rome. His pictures are not uncommon, and often extremely beautiful in their composition and the expression of their heads. Dosso Dossi (b. 1474, d. 1558) and his brother were contemporaries of Garofalo in the school of Ferrara. Finally, among the pupils of Raphael must be reckoned the Netherlander Michael Coxis, of whom we shall speak hereafter. In the mean time a second Sienese school had arisen. Jacopo Pacchiarotto was a successful imitator of Pietro Perugino. Giantonio Razzi, commonly called Il Sodoma (b. 1480, d. 1554), seems to have been influenced by Leonardo; his forms are feminine and graceful, with considerable power of expression. His best works are to be seen in S. Domenico of Siena, and at the convent of M. Oliveto Maggiore. Domenico Beccafumi, surnamed Meccherino (b. 1549), worked with Razzi. His forms are good and his colouring pleasing. The inlaid pavement of the cathedral of Siena is principally from his designs. Baldassare Peruzzi (b. 1481, d. 1536) is better known as an architect than a painter.

To turn to the north of Italy, Antonio Allegri, or, from his birth-place, 'Correggio' (b. 1494, d. 1534), probably was instructed in the school of Mantegna, but after the death of Andrea. Nothing in the history of art seems so *premature* as the style of Correggio. His expression, to say the least of it, often borders on affectation. His early picture at Dresden shows the same colouring which he afterwards carried to such perfection. No other artist ever played with light and shadow as he was wont to do. His half tones and his reflected lights produce the effect of illusion. He knew his power, and delighted in displaying it in the conquest of difficulties from which other masters shrank. The finest works of Correggio are, the Notte and other pictures at Dresden; the St. Jerome at Parma; the frescoes in the cathedral of that city, and in the convent of St. Paul. Those purchased from the Marquis of Londonderry for the National Gallery, especially the Ecce Homo, are excellent specimens of the master. The tendency to affectation visible in Correggio was a dangerous legacy to the school of Parma, and its evil consequences are especially visible in the works of Francesco Mazzuoli, or Il Parmigianino (b. 1503, d. 1540), to whom however it is impossible to deny great power and great feeling for beauty.

The *Roman School* had cultivated beauty of form and expression, Correggio perfected chiaroscuro, and it was in Venice that colouring attained its highest pitch. We have remarked the tendency to brilliant local tints in the latter school at a very early period. Giorgio Barbarelli da Castelfranco, or Giorgione (b. 1477, d. 1511) steeped in a rich glow of mellow light those full forms of Venetian beauty which hold a middle place between the clumsiness of the Flemings and the more slender outlines of the other Italian schools. The most eminent of Giorgione's scholars was Sebastian del Piombo (b. 1485, d. 1547). His portraits are very grand, and his historical pictures, like our Raising of *Lazarus*, combine the design of M. Angelo with Venetian colour. The style of Giorgione had much [illegible] Jacopo Palma Vecchio and on his great pupil Tiziano Vecellio (b. 1477, d. 1576).

We possess in England good specimens of Titian's works, especially in the National, the Bridgewater, and Fitzwilliam Galleries (at Cambridge). The brilliancy of his high lights and the ruddy transparency of the skin in his flesh are most marvellous; his large compositions, which, like most of his countrymen, he executed in oil instead of fresco, must be seen at Venice. It is impossible to conceive more delicious landscapes than those of his backgrounds, or more reality than animates his portraits. Bonifazio (b. 1491, d. 1553), Andrea Schiavone (b. 1522, d. 1582), and Alessandro Bonvicino, called Il Moretto of Brescia (b. 1564), were distinguished imitators of Titian. Gio. Batista Moroni, an admirable portrait-painter (b. 1525, d. 1578), was a pupil of Moretto. Pordenone (b. 1484, d. 1539) and Paris Bordone (b. 1500, d. 1570) are remarkable for the softness and richness of their colouring and the expression of their heads, especially in portraits. The most productive painter of the whole Venetian school, which maintained its original character and force for a considerable period, was Jacopo Robusti, called, from his father's trade, Il Tintoretto (b. 1512, d. 1594). He painted much by lamp-light, and thus acquired a blackness in his shadows which is sometimes unpleasing, but his own facility of execution was the real bane of his reputation. Some of his works, such as the Crucifixion, in the school of St. Roche at Venice, are as large as scenes in a theatre, and his pictures are most unequal.

At Verona, Paolo Caliari, or Paolo Veronese (b. 1528, d. 1588), applied in a peculiar way the principles of the Venetian masters. The brilliancy of his banquets and festal scenes is perfectly astounding, and full effect is given to the force of his local tints and richness of his stuffs by the cool transparent atmosphere of the backgrounds. The best specimens of his works are, the large picture in the Louvre, Christ at Levi's table in the Doge's palace, and Mary Magdalen at Christ's feet in the Durazzo palace at Genoa. His son and scholar Carlo Caliari was far inferior to his father. The family of Da Ponte, from Bassano, produced three painters. Jacopo, the father (b. 1510, d. 1592), after studying at Venice, returned to his native place, and painted innumerable representations of country and household life, or sacred scenes disguised as such, in a strong and rich colouring. His two sons, Francesco and Leandro, have left some good pictures at Venice.

We have now arrived at the period when art appeared destined to decline. Venice was in some degree an exception; but at Florence, exaggerated anatomical display, the attitudes of academic models, and hard opaque colour are the characteristics of many of those masters who thought they were following M. Angelo. Such for the most part, at least in their historical pictures, were Giorgio Vasari, the historian of painting (b. 1512, d. 1574), Angelo Bronzino (b. 1501, d. 1570), and Alessandro Allori, his scholar, also called Bronzino (b. 1535, d. 1607). While Giuseppe Cesari, surnamed the Cavaliere d'Arpino (b. 1560, d. 1640), enjoyed a great reputation at Rome, Prospero Fontana (b. 1512) and his daughter Lavinia, with several other masters, were distinguished at Bologna; but the real spirit of art had fled. Empty conventional forms and facility of execution were all that remained in the place of the sterling qualities of the older masters, who were often despised as dry, harsh, and formal.

Towards the end of the sixteenth century, the re-action from the Reformation which pervaded the Roman Church began to be felt in the arts also. The Jesuits were fast recovering the ground lost in what may be called the heathen days of the papacy.

Palestrina spiritualised the music of the church, and the Carraccis to a certain extent revived the sister art of painting. The founder of their school was the uncle Ludovico (b. 1555, d. 1619), a pupil of Prospero Fontana and Tintoretto. His nephew Annibale (b. 1560, d. 1609) and Agostino (b. 1558, d. 1601) zealously seconded his efforts, and they opened an academy at Bologna. The study of the antique and of nature was united to the endeavour to appropriate the characteristic excellence of each most distinguished master—a principle from which they derived the name of the Eclectic school, and which of itself can lead to little. It appears indeed incompatible with the unity and individual feeling necessary for a work of art. They succeeded however in elevating the character of painting far above that which it bore in the hands of their immediate predecessors, and joined earnestness and devotional feeling to great technical excellence. Ludovico has the merit of being the teacher; Agostino painted less than the other two, and Annibale is without doubt the most distinguished. His frescoes in the Palazzo Farnese at Rome, and his pictures in the gallery at Bologna, especially the former, give the best idea of his real worth. From this school of the Carracci issued a series of great masters, of whom the following were the most eminent. Domenico Zampieri, or Domenichino (b. 1581, d. 1641), in whose works a thorough feeling for beauty and great strength of conception and execution are visible. His most celebrated oil picture is the Communion of St. Jerome, in the Vatican, in which however the composition is partially imitated from Agostino Carracci; his best frescoes are that in the cathedral at Fano, in St. Luigi at Rome, and those at Grotta-ferrata. Like Annibale Carracci, he was an admirable landscape-painter. Francesco Albani (b. 1578, d. 1660) painted Cupids and groups of a mythological character, which seldom rise above prettiness. His best scholars were Gio. Batista Mola (b. 1620), Carlo Cignani (b. 1628, d. 1719), and Andrea Sacchi (b. 1594, d. 1668). A very fine picture by the last master is in the Vatican. Carlo Maratta (b. 1625, d. 1713) was his scholar. Guido Reni (b. 1574, d. 1642) stands among the first of the Bolognese school. His conception of beauty, formed by a contemplation of the antique, would be more satisfactory if it possessed more individual life, and was free from the somewhat insipid sameness of a mere abstraction. In his early works he painted with great strength. The Massacre of the Innocents, the large Pietà, and the Crucifixion, in the Gallery at Bologna, belong to this period. The Aurora, in the Palazzo Rospigliosi, is of his middle style, when he painted with a warmer colouring than in his later works, in which the tone is often leaden, and the forms, though beautiful, are vague and spiritless. Gio. Francesco Barbieri, surnamed Guercino da Cento (b. 1590, d. 1666)) showed perhaps greater power of expressing passion than Guido, and was less attracted by an ideal type. In his early works there is a force and fullness of shadow, which was exchanged afterwards for a lighter and milder manner. His St. William at Bologna, and St. Thomas in the Vatican, are good specimens of the former; the Abraham and Hagar, at Milan, of the latter style. Guercino holds a sort of intermediate place between the Eclectic school and the Naturalists. In the hands of Lanfranco (b. 1581, d. 1647) painting again degenerated into a mere handicraft, with great exaggeration, but little real expression. Gio. Batista Salvi (b. 1605, d. 1685), called from his birthplace Sasso-ferrato, is supposed to have been a pupil of Domenichino. His pictures have no great depth or force, but show considerable beauty without affectation.

Another Eclectic school, that of the Procaccini, arose at Milan, which produced, among other masters, Gio. Batista Crespi (b. 1557, d. 1653) and his son Daniele. At Rome, Federigo Baroccio of Urbino (b. 1528, d. 1612) imitated the style of Coreggio. His best followers were Ludovico Cardi da Cigoli (b. 1559, d. 1613), and Cristofano Allori, a son of Alessandro (b. 1577, d. 1621). The Judith of the latter, in the Pitti, is a very fine picture. Carlo Dolci (b. 1616, d. 1686) followed much the same course as Sasso-ferrato, but not always with as little affectation. A high finish and smooth cold colour often hold the place of higher qualities. Pietro Berettini da Cortona (b. 1596, d. 1669) laid the foundation of that empty mannerism in Italian art which prevailed through the latter part of the seventeenth and the whole of the eighteenth century.

Opposed to the Eclectic schools were those masters who seem to have imagined that a true imitation of nature consisted in appropriating to every and any subject the first forms which came in their way, instead of selecting such as thoroughly suited the conception of the particular scene to be treated, and imitating those as closely as possible—too closely it cannot be. The vague notion of the ideal on the one hand and of indiscriminately copying vulgar nature on the other, are opposite and equally fatal errors. The leader of the 'Naturalists' was Mich. Angelo Amerighi da Caravaggio (b. 1569, d. 1609), whose force of execution was very great, and who often rose to real pathos in his expression. Among his scholars were two Frenchmen, Valentin and Vouet. At Naples, where the 'Naturalists' opposed in the olent manner all encroachments of the other school, e Ribera, or Lo Spagnoletto (b. 1592, d. 1656), has Martino a masterly Descent from the Cross. There much that reminds us of his native country. He was dark and powerful in his shadows, and shrank from the representation of no scene however horrible. Salvator Rosa (b. 1615, d. 1673) was a man of most varied powers. His landscapes (often wild scenes in the Apennines) and his battle-pieces are best known and superior to his historical pictures. Luca Giordano, surnamed 'Fa Presto' (b. 1632, d. 1705), may be considered as closing the seventeenth century. We ought to mention that at Venice during that period, though art undoubtedly declined, still much that is good may be found in the works of Jacopo Palma the younger (b. 1544, d. 1628), and in those of Alessandro Varotari, or Il Padovanino (b. 1570, d. 1650). In the eighteenth century Antonio Canale (b. 1697, d. 1768) and his nephew Bernardo Bellotto or Canaletto (b. 1724, d. 1780) executed those well-known views which have never been exceeded for truth and out-door effect.

Northern Schools.—Illuminated MSS. still remain as monuments of German art in the ninth and tenth centuries. The marriage of Otho II. (978-983) with the Greek princess Theophania probably gave the German artists access to the technical skill of the Byzantines. Towards the end of the twelfth and beginning of the thirteenth centuries visible signs of new life in art begin to show themselves. In the 'Parcival' of Wolfram von Eschenbach, who lived early in the thirteenth century, the painters of Cologne and Maestricht are especially mentioned, and the figures of the Apostles, one of which bears the date 1224, in the church of St. Ursula in the former city, are probably the oldest German pictures extant. In the reign of Charles IV. (1346-78) artists seem to have existed in Bohemia; but towards the close of the fourteenth century the school of Cologne was the most distinguished. Meister Wilhelm is spoken of by a contemporary chronicler, in 1380, as the best master of his day. Pictures of his are to be seen in St. Castor at Coblenz, St. Clara in Cologne, and in the Boisserée collection. The great altar-piece, formerly in the chapel of the town-hall, now in the cathedral of Cologne, is supposed to have been painted by Meister Stephan, and bears the date 1410. The richness of the colouring rivals that of Giorgione, and the dignity and beauty of the Virgin are most remarkable. A branch of the Cologne school appears in Westphalia in the beginning of the fifteenth century. No connection has been traced between the German and old Flemish masters, though such probably existed. Hubert and John van Eyck (b. 1366, d. 1426, and b. 1400, d 1441) united the majestic simplicity of the old Christian type with a close imitation of external nature and a homely strength characteristic of their country. Their sister Margaret also was an artist. John van Eyck may be said to have 'republished,' though he probably did not invent painting in oil. The great work of the two brothers was the altar-piece in St. Bavo at Ghent, painted for Judocus van Vyt. It consisted of a centre picture of the Worship of the Lamb, surmounted by God the Father, the Virgin, and St. John, and flanked by folding shutters, all relating to the principal subject. The different parts of this painting, unquestionably one of the grandest productions of modern art, are now separated. The upper and middle portions remain at Ghent; the others are at Berlin. Michael Coxis executed a copy of it for Philip II., which is still more scattered. The school of Van Eyck was fertile in good painters; among them were Gerard van Meeren, Hugo van der Goes (some of whose pictures are to be found in Italy), Roger van Brügge, and more especially his pupil Hans Hemling or Memling. Some beautiful works of this last master are preserved in St. John's Hospital at Bruges, of which he was an inmate about the year 1479. Towards the close of the fifteenth century we find a kindred school to that of Flanders existing at Cologne; and the same feeling may be traced in the engravings and pictures of Martin Schoen, or Schöngauer of Colmar, who painted about 1460. Hans Holbein the elder, of Augsburg, worked about 1500, but it was at Nürnberg that the German school displayed its full power. Michael Wohlgemuth, of that city (b. 1434, d. 1539), was the master of Albert Dürer (b. 1471, d. 1528), a painter who scarcely shrinks from comparison with any of his great Italian contemporaries.

The earliest undoubted picture of Dürer's is his own portrait in the Florence Gallery; among his latest and most assuredly his finest works are the Apostles, now in the Munich Collection. In 1506, Dürer visited Venice, but the Venetian school does not seem to have exercised so much influence over him as that of Flanders probably did in a journey undertaken at a later period (1520-1). Of Dürer's excellence as an engraver we need not speak here. The principal artists of the Nürnberg school, after its great leader, were Hans v. Kulmbach, Henry Aldegrever, Bartholomew Beham, Albert Altdorfer, and George Pens. The last became a pupil of Raphael. In Saxony, Lucas Cranach (b. 1472, d. 1553) was court painter to the three electors, Frederic the Wise, John the Steadfast, and Frederic the Magnanimous. He accompanied the first to the Holy Land in 1493, and shared the prison of the last after the battle of Mühlberg (1547). At a later period he was burgomaster of Wittenberg and a friend of Luther, whose marriage with Catherine von Bora he contributed to bring about. His pictures are fanciful, and the features of his females much similar. Lucas Cranach, the son, was also a painter. In Holland we ought to notice Cornelius Engelbrechtsen (b. 1468, d. 1533), and his more celebrated pupil Lucas of Leyden (b. 1494, d. 1533); and we must close our notice of the old German school with Hans Holbein the younger (b. 1498, d. 1554), who came from Basle to England, where he died in the service of Henry VIII. Most of his portraits remain in this country. The Dresden Gallery possesses a beautiful picture by him of the Virgin and Child, with the family of Jacob Meyer of Basle kneeling at her feet.

In looking at the general character of the old German masters, we see a vigour of conception and power of technical execution equal to any exhibited by the Italians; but they are the 'Romantic' school contrasted with the 'Classic.' The medium through which they saw nature was more tinged with the individual and national peculiarity of each artist; and there is visible in almost all their works a certain whimsical and *fantastic* feeling totally different from anything to be seen in the old Florentine or Sienese painters. We must pass briefly over Quintin Messys, the blacksmith of Antwerp (b. 1466, d. 1529), whose Misers at Windsor are well known. The later works of John Mabuse (b. 1499, d. 1562) and the pictures of Michael Coxis (b. 1497, d. 1592) show that forced imitation of the Italians which characterises the transition from the old Flemish to the school of Rubens. This tendency is more strongly marked in Franz Floris (b. 1520, d. 1570), in the elder and younger Franks (b. 1545, d. 1616; b. 1580, d. 1642), in Bernard van Orley (b. about 1470), and Otho Venius (b. 1556, d. 1634), the master of Rubens. The works of these artists and their contemporaries are deficient in independence and genuine beauty, though they interest us as being the groundwork of the school of Rubens.

The Spanish Netherlands, rescued from Protestantism by Don John of Austria and the prince of Parma, witnessed, in the commencement of the seventeenth century, a revival of painting more striking perhaps than that effected by the Caracci. Peter Paul Rubens was born at Cologne in 1577, and died at Antwerp in 1640. After leaving the school of Otho Venius, he visited Italy, and studied particularly the works of Titian and P. Veronese. His earlier pictures are more attractive than those which were executed when the ever-increasing number of commissions obliged him to employ unsparingly the pencil of his pupils. The 'Descent from the Cross,' in the cathedral of Antwerp, and its companions, are deservedly cited as among the best specimens of this master. His works may be studied in the greatest perfection in the museum and church of Antwerp, in the gallery of Vienna, and more especially at Munich. In our own country, the Blenheim collection is peculiarly rich in first-rate pictures by Rubens. He is equally great in history, in landscape, and in portrait. To complain that the fire of his genius was not chastened as in the great Italian masters, is to wish that the artist had been a different individual from what he was formed to be. When we look at Rubens's works, their facility of execution, their energy, and their brilliancy hurry us beyond such considerations; when we think of them, we may regret that his forms are often ill-selected, and that the brute animal vigour of his bacchanals is pushed to coarseness.

The most celebrated of the pupils of Rubens was Antony van Dyck (b. 1599, d. 1641). At first he imitated closely the peculiarities of his master, but after his residence in Italy he adopted a more tranquil tone of feeling and soberer colour. His historical pictures are very fine, but not equal in every way to the numerous and admirable portraits, many of which were executed during a residence in England, and still remain in this country.

Of the other scholars of Rubens, few did more than imitate and sometimes exaggerate the outward characteristics of their leader. The best among them were Jacob Jordaens (b. 1594, d. 1678) and Gaspar de Crayer (b. 1585, d. 1669).

In Holland, Michael Mirevelt (b. 1567, d. 1641) and Franz Hals (b. 1584, d. 1666) painted history and portraits, especially the latter, with great success. Bartholt van der Helst (b. 1613, d. 1670) approached very closely to Vandyck in colour. His finest work, the Festival given by the Burgher-guard of Amsterdam on the conclusion of the treaty of Westphalia, is in the museum of that city. Another excellent picture of smaller dimensions is in the Louvre.

The great master of the Dutch school however was Paul Rembrandt van Ryn (b. 1606, d. 1674). In his portraits and ideal heads we find the most wonderful truth and dignity, but his peculiar power consisted in a mastery of light and shade, which rendered the lowest subjects vehicles for high and poetical feeling. The depth and brilliancy thus produced seem hardly attainable by mere colour on a flat opaque surface, and when we look at his numerous etchings, we marvel still more how his needle on the copper has almost surpassed his pencil on the canvas. Conscious of his power to attain sublimity by light and shade alone, he seems often to have rejoiced in showing how that one charm could make us heedless of coarseness of conception and meanness of form. Rembrandt's principal pupils and imitators were Gerbrand van den Eeckhout (b. 1621, d. 1674), Ferd. Bol (b. 1611, d. 1681), who excelled in portrait, Nicholas Maas (b. 1632, d. 1693), and Salomon Koning (b. 1609). Of another pupil, Gerard Dow, we shall speak immediately.

It is necessary just to mention Gerard Honthorst, called by the Italians Gherardo delle Notti (b. 1592, d. 1660), who imitated Caravaggio and the Italian 'Naturalists.' His effects of torch and candle light are much celebrated. Gerard Lairesse (b. 1640, d. 1711) is best described as a Flemish imitator of Nicolas Poussin. Adrian van der Werff (b. 1659, d. 1722) has little to recommend him besides a finish and smoothness of surface, to which higher qualities are sacrificed; his human figures present the texture of ivory rather than of flesh, with much affectation and little genuine expression of passion or character.

We must now turn to those masters who are most distinguished in what is called 'Genre,' a word for which it is difficult to find a substitute and still more difficult to furnish a definition. The subject may be real or fictitious, but if the picture is on a small scale, and the object of the artist has been the expression of humour, or the prettiness of colour, or of light and shade; if those qualities which are accessories in great works have been to him ends, then it seems to come within the negative class, designated by the French word used above. It is the popular side, the every-day life of art, as contrasted with the epic grandeur of historical or the enthusiasm of devotional works.

Peter Breughel the elder (b. 1510, d. 1570) was called Boor-Breughel, from the subjects of many of his pictures, as his son, Peter Breughel the younger, obtained the name of Hell-Breughel, from the fantastic scenes which he portrayed. The Temptation of St. Anthony was in like manner a favourite subject of the elder Teniers (b. 1582, d. 1649), who by no means equalled his son and pupil David Teniers (b. 1610, d. 1690) in those scenes of merry-making and peasant life for which he is so celebrated. Nothing can surpass the reality of the vulgar *comfort* with which his single figures sit and smoke, or the drunken gaiety of his larger assemblies. His colour is cool and his touch firm and vigorous. Sometimes he amused himself with imitating the works of masters of a different cast. In Adrian van Ostade (b. 1610, d. 1685) we have the same subjects treated in a warmer and more mellow tone, but perhaps with less individual truth and character, though with greater attention to general effect, than by Teniers. Isaac van Ostade painted fewer interiors, and followed his brother's style, with less success. The humour of Adrian Brouwer (b. 1608, d. 1640), who is reported to have mixed deeply in the scenes which he painted, is of a broader cast. In Jan Steen (b. 1636, d. 1689) there are satirical touches and a genuine comic unity which equal Hogarth. The picture in the Duke of Wellington's gallery is an excellent specimen of these qualities. There is another department of 'Genre,' which bears the same relation to the drinking-bouts of Teniers or Brouwer that genteel comedy does to broad farce. In this Gerard Terburg and Gerard Dow stand pre-eminent. The former (b. 1608, d. 1681) threw into the scenes which he represented a delicacy of feeling and a sort of decorum which add greatly to the value of his execution and high finish. Of this kind are the celebrated Satin Gown, engraved by Wille, the Trumpeter at Munich, and the Cavalier and Lady in the Louvre. Gerard Dow (b. 1613, d. 1680) was the pupil of Rembrandt, from whom he gained a thorough knowledge of light and shade, and a feeling for general effect which preserved his elaborate execution from all tediousness, while he secured by it a wonderful reality in the household scenes which he delighted to paint. In some of his pictures, as in that of the Dropsical Lady, there is great pathos. Gabriel Metzu (b. 1615, d. 1658) was the best imitator of Terburg. Franz Mieris, a scholar of Gerard Dow (b. 1635, d. 1681), equalled his master in fineness of finish, but not in genuine feeling. Caspar Netscher (b. 1639, d. 1684) and Eglon van der Neer (b. 1643, d. 1703) painted in the same style. The interiors of Peter van Hooghe (b. 1659, d. 1722) are remarkable for magical effects of light.

The great Italian painters Giorgione and Titian were admirable in landscape. Annibale Caracci and Domenichino have left excellent pictures in this department. But as if the ugliness of the country stimulated its natives to study all the aids which make an ordinary scene picturesque, it was in Flanders and in Holland that landscape painting was most cultivated. In the school of Van Eyck, the backgrounds are often elaborately imitated from nature: Joachim Patenier (b. 1487) and Herri de Bles (b. 1480, d. 1550) executed works in which the landscape claims an independent existence and the figures have already become accessories. John Breughel, or 'Velvet-Breughel' (b. 1569, d. 1625), copied with wonderful minuteness all the variety of vegetation. Contemporary with Annibale Carracci there lived at Rome a Flemish artist, Paul Bril (b. 1554, d. 1626), who forms a sort of link between the landscape painters of the north and south.

In that kind of landscape the excellence of which consists in grandeur and the form of the large masses, Nicolas Poussin led the way. He was followed by Gaspar Dughet, or Poussin (b. 1600, d. 1663), and Sebastian Bourdon (b. 1616, d. 1671). Claude Gelée was a native of Lorraine (b. 1600, d. 1682); he was the first educated by A. Tassi, a scholar of P. Bril, but nature, and nature alone, taught him to tinge his graceful forms of foliage and his rippling water with the cool pearly hue of morning or the rich glow of an Italian evening. His pictures acquired in his lifetime the value which they have ever since maintained.

The style of Claude reacted on the Low Countries. Hermann Swanevelt (b. 1620, d. 1680) was his pupil: John Both (b. 1610, d. 1651) and Adam Pynacker (b. 1621, d. 1673) were painters of the same character. The Dutch landscape painters kept closer to Northern nature: such are the works of John van Goyen (b. 1596, d. 1656); generally low sea coasts, executed in a brown transparent tone. Anthony Waterloo (b. 1618, d. 1660) is better known by his admirable etchings than by his pictures.

The genius of Rembrandt exercised considerable influence over landscape. But the leaders of this particular school were Jacob Ruisdael (b. 1635, d. 1681) and his pupil Mindert Hobbema (b. 1611). The best works of these masters carry us into the depth of the forest and convey that sort of lonely feeling which retired woodland scenery imparts. Albert Everdingen (b. 1621, d. 1675) gave his pictures more of the Norwegian character, and often painted waterfalls and pine-forests.

We have said nothing of the pastoral side of landscape, in which Nicolas Berghem (b. 1624, d. 1683), Albert Cuyp (b. 1600), Carl du Jardin (b. 1640, d. 1678), and Adrian van der Velde (b. 1639, d. 1672), excelled. Philip Wouvermans (b. 1620, d. 1668) pursued a line peculiar almost to himself, or in which at least he has no rival. He executed battles, fairs, halts of cavalry, and all scenes in which horses occur, with exquisite truth and delicacy.

The most eminent marine painters were Bonaventura Peters (b. 1614, d. 1652), Ludolf Backhuysen (b. 1631, d. 1709), and William van der Velde (b. 1610, d. 1693). Franz Snyders (b. 1579, d. 1654), John Fyt (b. 1625, d. 1700), and John Weenix (b. 1644, d. 1719), painted animals. The first of the three executed large hunting-pieces in conjunction with Rubens.

Spanish School.—The Flemish masters, as might be expected, seem to have exercised an early influence in Spain, especially two, known as Maestro Rogel (1445) and Juan Flamenco (1496), who are supposed by some to have been Roger van Brügge, a pupil of J. van Eyck, and John Hemling. The works of Luis de Morales of Badajoz (d. 15[illegible]) show some traces of early Flemish minuteness and hardness, with great power of expression, occasionally exaggerated. Fernando Gallego imitated Albert Dürer. Antonio del Rincon (b. 1446, d. 1500), Alonso Berruguete (b. 14[illegible], d. 1562), Pedro Campaña, a Fleming by birth (b. 1503, d. 1580), Luis de Vargas (b. 1502, d. 1568), and Vicente Joanes of Valencia (b. 1523, d. 1579), were the earlier Spanish masters of eminence who studied in Italy.

The works of Rincon are rare: there is an altar-piece of his at Robledo de Chavela, not far from the Escurial. Campaña's Descent from the Cross, and the celebrated Gamba of Vargas, are in the cathedral of Seville. The series of the Martyrdom of St. Stephen, by Joanes, is in the museum of Madrid. Alonso Sanchez Coello (d. 1590) and Juan Fernandez Navarrete el Mudo (b. 1526, d. 1[illegible]) painted respectively portraits and sacred subjects for Philip II. The colouring of Navarrete is very fine, and resembles that of the Venetian school.

In the school of Seville, in the seventeenth century, the principal forerunners of Murillo were Juan de las Roelas (b. 1558, d. 1625), whose finest picture is perhaps the Death of St. Isidore, in the church of that saint (1833) at Seville; the two Herreras, and Francisco Zurbaran (b. 1598, d. 16[illegible]). The elder Herrera (b. 1576, d. 1656) is distinguished for vigour and boldness of execution. Zurbaran's great work of St. Thomas of Aquino, formerly in the Colegio de San Tomas, will bear comparison with the best pictures of any master. Bartolomé Esteban Murillo (b. 1618, d. 1682) has left early pictures at Seville which give little promise of his subsequent excellence. It was only after his return from Madrid in 1645 that he attained that freedom and power which characterise his best works. The name of Murillo is supposed in this country to stand highest in the Spanish school, but we are of opinion that Diego Velasquez de Silva (b. 1599, d. 1660) was the greater man of the two. His portraits are inimitable: his historical works in the Madrid Gallery, such as the Surrender of Breda, and his sketches of landscape in the same collection, are of great excellence. One of his most celebrated early pictures is the Water-carrier, now at Apsley House.

Alonso Cano of Granada (b. 1600, d. 1667) painted with a fine feeling of simplicity and beauty. Francisco Ribalta (b. 1551, d. 1628) is generally held to be the best master of the Valencian school. The altar-piece in the chapel of Magdalen College, Oxford, is probably by him. Claudio Coello (d. 1693) is one of the last Spanish masters who deserve notice. His picture in the Sacristy of the Escurial is a first-rate work.

French School.—Leonardo, Andrea del Sarto, Rosso, and Primaticcio were among the Italians whom the zeal of Francis I. introduced into France; but we find little independent existence of French painting before Simon Vouet (b. 1582, d. 1641), who studied the later Venetian painters and Caravaggio: his contemporary Nic. Poussin (b. 1[illegible], d. 1665) stamped a character on the art of his country, which may be said to have lasted to our own days. His style is based in some degree on a confusion of the capabilities of sculpture and painting—statuesque forms, [illegible] drawing, and the composition of a bas-relief clothed in [illegible] pleasing colour, though not wholly satisfactory to the eye, still combine to produce considerable effect; an effect however of a limited kind, analogous to that resulting from the classical correctness of Racine's tragedies. Gaspar Poussin and Claude Lorrain have been already named. The best of Vouet's scholars was Eustache Le Sueur (b. 1617, d. 16[illegible]). Peter Mignard (b. 1610, d. 1695) and Charles Le Brun (b. 1619, d. 1690) were pupils of the same school. The portraits of the former are good: the large pictures of Le Brun were disfigured by the affectation of the time of Louis XIV. Antoine Watteau was born in 1684, and died in 17[illegible]. Joseph Vernet (b. 1711, d. 1789) executed some beautiful landscapes and sea-pieces. J. B. Greuze (b. 1726, d. 1[illegible]) excelled in the representation of scenes of domestic In later times, Jacques Louis David (b. 1748, d. 1[illegible]) carried out on a larger scale the principles of Poussin. It is impossible to deny his pictures the merit of fine drawing and a certain power; but disagreeable colour, exaggerated theatrical expression, and academic affectation mar the effect of their better qualities. His most eminent followers were Gérard, Gros, Girodet, Guérin, and Géricault.

English School.—Except the portrait-painters, Dobson, Oliver, and Cooper, in the reign of Charles I., we cannot name an English artist of any eminence until we arrive at Hogarth (b. 1697, d. 1764); for his father-in-law Sir James Thornhill hardly deserves notice. The reader will find a more detailed account of Hogarth in the article which bears his name. No imitator has at all reached his peculiar excellence. Boydell's Shakspere Gallery certainly caused a feeling for art, and contributed to the spirit which prevailed in England at the end of the last century. Sir Joshua Reynolds (b. 1723, d. 1792) still remains the first on the list of English portrait-painters. His historical pictures are of very inferior merit. No portrait was perhaps ever painted which represents character more vividly, and tells its story better, than that of Lord Heathfield. Many of his female portraits are equally successful. His colour was excellent, though not always lasting. George Romney (b. 1734, d. 1802) has left some works which almost rival Reynolds. The earlier works of Benjamin West (b. 1738, d. 1820) make us *feel* more strongly the mannered uniformity and coldness of his later pictures. James Barry (b. 1741, d. 1806) had at least the merit of daring to undertake a work of the greatest magnitude. John Opie (b. 1761, d. 1807) was one of our most powerful masters, and certainly superior to Northcote. Wilson (b. 1714, d. 1782) and Gainsborough (b. 1727, d. 1788) must be looked on as the founders of the English school of landscape-painting. We cannot but lament that the Raphaelesque purity of Stothard's early designs was afterwards exchanged for the prettinesses of Watteau. It is impossible to deny poetical imagination and grandeur to Fuseli, though these qualities are obscured by overcharged and mannered drawing.

In our own day Lawrence executed portraits inferior only to those of Reynolds; but they possess rather more of the conventional tone of the fashion of the time in which the artist lived than is found in the best works of Sir Joshua Reynolds.

It remains to look round and see what is the promise of European art at the present time. In Italy and in Spain little has been *done* in this century. The influence of the school of David is visible in the works of Camuccini in the former country, and in those of Madrazo and Aparicio in the latter. Political events have doubtless contributed to bring about these results. In Germany a new era has commenced. We have passed too rapidly over the ground to notice Oeser (b. 1717, d. 1799), Raphael Mengs (b. 1728, d. 1779), Angelica Kauffman, and others; but at the present moment the schools of Düsseldorf and Munich are producing works whose celebrity will be lasting. Fresco-painting has started into life again with fresh vigour in the latter capital. In Overbeck, who resides at Rome, we find the purity and beauty of the Umbrian school renewed. Cornelius, Julius Schnorr, and Henry Hess, though far from faultless, have worked most successfully under the patronage of the king of Bavaria. At Düsseldorf, Lessing and Bendemann are two very distinguished artists, and painters of considerable eminence are not wanting at Berlin. Among modern French pictures the battle-pieces and historical works of Horace Vernet hold a high place. Leopold Robert is celebrated for his scenes of Italian rural life, Granet for his interiors, Gudin and Isabey for their sea-pieces. Delaroche and Eugène Devéria are traitors to the principles of David, and may be considered as the chiefs of a romantic school of French historical painting.

In England there is, as there ever has been, little demand for large historical works. Yet at the present moment no portrait painter of great excellence has filled the place of Lawrence. The earlier works of Wilkie are well known; to our eye there is in his later pictures a slightness and want of substance which is not compensated for by their facility of execution. Leslie and Mulready deservedly possess a high reputation in that walk of art which Wilkie seems inclined to abandon. Etty's colour and form are so fine that we regret the frequent absence of chaste feeling and the predominance of academical display. The characteristic excellence of Eastlake's pictures may be said to be their purity of taste and the evident marks which they bear of a highly cultivated mind, deeply imbued with the feeling of the older masters. The same refinement is visible in the exquisite landscapes of Calcott. No genius was ever more versatile than that shown by Turner. The gloomy grandeur of the Last Plague of Egypt, which is as simple as a landscape of Nicolas Poussin, contrasts singularly enough with the gorgeousness of the Rise of Carthage or the Italy. Without pretending to defend some of his extravagances of colour, it must be remembered that many pictures of Turner's, which now appear sober, were too gaudy for the public taste when they were painted, and only obtained gradually the rank which they hold at the present day.

As a painter of animals, Edwin Landseer far surpasses any of the old masters, and stands unrivalled for softness, breadth of touch, and wonderful expression of character. One remarkable feature in modern English art is the high class of works executed in water colours.

(Müller, *Handbuch der Kunst*; Smith, *Catalogue Raisonné*; Vasari, *Vite dei Pittori*; Lanzi, *Storia Pittorica*; Rumohr, *Italienische Forschungen*; Kugler, *Handbuch der Geschichte der Malerei*; Waagen, *Kunstwerke und Künstler in England und Paris*; Cean Bermudez, *Diccionario de las Bellas Artes*; Passavant, *Kunstreise durch England und Belgien*; Pilkington's *Dictionary of Painters*.)

PAINTING, HOUSE, is the art of painting the interior and exterior of our dwellings and other buildings with a composition which shall preserve from decay, please the eye, and render the surface to which it is applied less liable to soil and easier to be cleaned. It is executed either in oil or distemper.

In oil the principal tools employed are brushes made of hogs' bristles for large surfaces, and sash-tools made of finer hair for small work, as mouldings, window-bars, &c. After being used, they are kept in water to prevent their getting hard.

White lead is used for white colour; it is also the basis of all ordinary colours. The colouring substances (*stainers*) in general use are earths, umber, ochre, Sienna, Venetian red, purple, brown, &c.; the first three are sometimes burnt, a process which reddens and darkens them. Metallic compounds are red lead, vermilion, Prussian blue, chrome yellow, verdigris, Brunswick green, verditer, &c.

Animal and vegetable colours are lakes, indigo, ivory black, and lampblack.

All these require to be ground very fine in oil. This tedious and unwholesome process was formerly performed by hand, and by painters for their own use; but now the manufacturing chemists are enabled, by the application of machinery, to supply the articles cheaper than they can be prepared at home; and the painter, being relieved from this troublesome part of his business, will, if he aim at excellence in his profession, turn his attention to the higher branches of his art, and study the laws by which colours are related to each other, so as to be able to harmonise or contrast them as occasion may require.

The liquids in use are linseed oil (sometimes boiled with litharge to render it drying, and hence called *boiled oil*), and oil or spirits of turpentine, called *turps*. These are combined for use in various proportions according to circumstances: when the paint is required to bear a gloss, or is intended for outside work, most oil is used; and for black, chocolate colour, green, &c., outside, boiled oil alone, or with a very little turps, is best. For flatting, which has no gloss, turps alone is requisite. To all paint a little sugar of lead, or litharge (*dryers*), should be added to make it dry quick. It is important that all surfaces intended to be painted should be thoroughly dry, otherwise the paint will be liable to peel off.

With respect to mixing, the workman takes as much white lead as experience tells him is requisite, and a little oil or turps; and after these are mixed by stirring with a stiff knife, he adds dryers and a portion of one or more of the *stainers* above mentioned, according to the tint which he wishes to produce. After reducing the mass to the consistence of cream by the addition of turps or oil, the whole should be strained through a piece of canvas or muslin, when it is ready for use, and is termed by the workmen *colour*.

For the best work, the knots of yellow deal should be cut out to the depth of a quarter of an inch by the joiner, while the work is on the bench, and pieces of the same wood inserted in their places and glued in hand-tight only, for if compressed by a blow with a hammer, they will afterwards swell and spoil the surface. For general purposes the knots are painted with red lead and size. When this is dry, they are smoothed with glass-paper, and the work is ready for *priming*, which is composed of red and white lead ground in and mixed with linseed oil only. When dry, the work is again rubbed down with glass-paper or pumice-stone, and all nail holes, &c. are stopped with putty. The following coats contain about as much oil as turps, and are termed *second colour*, *third colour*, &c.; but the last coat previous to the finishing one is in all cases termed the *ground*, and is near the colour of the intended finish, except for black, green, and some other coarse dark colours, when the ground is lead-colour, composed of white and black mixed together.

The repainting of old work is the same as new, with the omission of the knotting and priming.

Stone-work, stucco, &c. are treated the same as wood. It is the general practice to repeat the coats, allowing sufficient time between each to dry, till the work ceases to absorb, which is known by the absence of dull spots and patches. It is also the practice to omit turps in mixing *colour* for work which is expected to absorb much. As to *graining*, the methods, tools, and materials adopted in this art vary with almost every workman, and it would be useless to attempt to describe in writing the processes which are so dependent on the artist's taste, but we may observe that the work having received a ground in oil of the predominating colour of the material to be imitated, the grain of wood is generally represented by semi-transparent colours mixed in beer. The subsequent varnishing fixes the colours, imparts a gloss, and defends the work from the weather.

Distemper.—The brushes for large surfaces differ from those used in oil: they are wider and flatter, and are termed distemper-brushes; but the tools for small work are similar. Whiting takes the same place in this branch that white lead holds in oil; the colouring substances are similar, but ground in water, and the fluids are water and melted size.

Mixing.—The whiting having been reduced to a stiff paste with water in which alum has been dissolved, the colouring matter is added, and the whole thinned with warm size. It must then stand till it gets cold, and it is not fit for use unless it *chills*, or forms a slight jelly. It is best to strain it after it has *chilled*, as the colouring substances will sometimes sink. Before applying this, the work must be well cleaned, for if there remains any substance which the fresh applied colour will soften and mix with, the work will not present a uniform appearance, but will be cloudy. The best work is painted first in oil, then flatted, and finished in distemper; but seldom more than one coat of distemper can be applied with advantage, for which reason care should be taken to cover every part equally, and particularly that the brush touch no part that is once dry; for this last reason several men are employed together, that the whole of any surface (as a ceiling) may be covered before any part has time to dry.

It is a generally received opinion among painters that white lead is the best material for painting work of all descriptions, with a view to its preservation, and they affirm that black paint is useless in that respect. Now, presuming that the durability of paint depends on the insolubility of the materials used in its composition, we might infer that black, which is composed of one of the most imperishable bodies known, namely carbon, in the state of lampblack, is more durable than white, which is made of carbonate of lead, a substance slightly soluble in water; and the following facts confirm this. To be able to judge fairly, we must have black and white of the same age equally exposed, and on the same material. These conditions are all fulfilled on finger-posts and other public notices exposed by the highways and on wooden grave-rails in country churchyards, which are almost invariably painted and written either black and white or white and black. Those with black grounds and white letters may often be seen with merely the illegible remains of the inscriptions while the ground is quite perfect. But the black writing frequently remains not merely till the white ground is washed away, but often till the surface of the wood, except where it is occupied by the letters, is decomposed to the depth of more than a sixteenth of an inch, actually leaving the inscription in relief; and although most general rules are said to have exceptions, the writer has never met with one to this.

PAINTING, ENAMEL. [ENAMEL.]

PAISIELLO, GIOVANNI, was born at Tarento in 1741, and entered at an early age in the Jesuits' College of that city, where he manifested so strong a disposition for music, that his father, an eminent veterinary surgeon in the service of Charles III., was prevailed on to place his son in the Conservatorio St. Onofrio at Naples, in which institution he was admitted in 1754, and during the following five years pursued his studies under the celebrated Durante. He there produced, among other compositions, a comic interlude, which at length became known in Italy, and in 1763 procured for him an order to compose an opera for the Teatro di Marsigli at Bologna. From that period the commencement of his professional career is to be dated, and it continued with undeviating success, till warned by approaching age, he wisely determined to relinquish his most active occupations, and enjoy in comparative ease his well-earned honours and moderate independence.

Paisiello's reputation was speedily established, and he soon accepted engagements to compose operas for every great city in Italy; in consequence of which he produced nearly fifty in the short space of thirteen years, the majority of which of course only enjoyed a short-lived triumph. In 1776 he entered into the service of Catherine II., and continued in Russia nine years, where he composed several operas, among which was his *Barbiere di Siviglia*; also an oratorio, *Il Passione*, and many sonatas, &c. He afterwards produced at Vienna, at the desire of Joseph II., *Il Re Teodoro*, and *La Molinara*; and for the same monarch wrote twelve symphonies.

On his return to Naples the king appointed him his *maestro di capella*, and settled on him a pension of 1200 ducats. The king of Prussia now wished him to visit Berlin, and the empress of Russia was desirous of his return to St. Petersburg, but he declined both engagements, as well as an invitation to London; but he composed for the King's Theatre *La Locanda*, which opera was subsequently performed at Naples under the title of *Il Fanatico in Berlina*. On the death of the French general Hoche, he produced a funeral symphony, for which he received a handsome present from Bonaparte; and about the same time brought out his *Zingari in Fiera*.

The revolution at Naples, in 1799, gave to that country a republican government, under which Paisiello accepted the office of 'National Director of Music;' but at the restoration of the royal family this was resented as an offence of magnitude, and he was suspended from all his public functions. In about two years however his services were found to be indispensable, and he was reinstated. Shortly after this he accepted an invitation from Bonaparte, then First Consul of France, to visit Paris, and was received in the most distinguished manner: a salary of 12,000 francs was assigned to him, and 18,000 more were added for his travelling and incidental expenses; besides which he was offered various high and profitable appointments, but declined them all except that of *maître de chapelle* to the head of the government. In Paris he produced thirteen masses, motets, &c., a *Te Deum* for Napoleon's coronation, and an opera, *Proserpine*, for the *Académie de Musique*. The air of France not agreeing with his wife's health, Paisiello returned in about two years and a half to Naples, but never failed to transmit to the French emperor a sacred composition for the anniversary of his birth.

A second revolution at Naples now placed Joseph Bonaparte on the throne of that kingdom, who confirmed Paisiello—who seems to have been very accommodating in his politics—in all his appointments, with a liberal augmentation of his salary; and the French emperor made him a chevalier of the legion of honour, with a stipend of 1000 francs. Other honours were showered on the composer, some of them not mere distinctions; and, to crown the whole, he was elected an associate of the French Institute. He died at Naples, in 1816. The city rendered him funeral honours, and his *Nina* was given at the great theatre on the evening of his interment, the king and the whole court attending the performance.

'Paisiello,' says the Chevalier Le Sueur, 'was not only a great musician; he possessed a large fund of information, was well versed in the dead languages, and conversant in all the branches of literature. . . . . Endowed with a noble mind, he was above all mean passions; he knew neither envy nor the feeling of rivalry.' To which we may add, that his compositions afford the most indisputable proofs of an accomplished and elegant mind. If they do not exhibit the energy of the more modern school—that is, of the school of Germany—they are never deficient in pathos, they abound in tenderness, and are invariably characterised by truth of expression—by the admirable judgment with which the sentiments of the poet are illustrated; and as a melodist, he is yet without a superior—witness, among a multitude of instances that might be cited, his 'Nel cor più non mi sento,' and 'Io son Lindoro' &c., 'Hope told a flattering Tale,' and 'For Tenderness form'd'), which are known, and will for ever be known, in every corner of the world where European music is cultivated. And though his operas, *Elfrida*, *Pirro*, *Il Barbiere di Siviglia*, *La Molinara*, *Nina*, &c. are eclipsed by the grander and certainly more complete instrumentation of that school of which Mozart is the model, yet, with additional accompaniments and skilful management, they might now be brought out successfully, and thus resuscitated, would be admitted to have lost none of those charms which beautiful air must always possess, and by which the last age was captivated.

PAISLEY, a town of Scotland, in the county of Renfrew, is situated on both banks of the White Cart, about three miles above the junction of that river with the Clyde, in 55° 48′ N. lat. and 4° 26′ W. long., and is 48 miles west by south from Edinburgh, direct distance. In the time of Agricola the Romans had a station here, and the present Bowling-green is traditionally said to have been the prætorium of the Roman fort. (Chalmers's *Caledonia*, i., pp. 91, 128.) About the year 1160 a priory was founded on the eastern bank of the Cart, by Walter, high-steward of Scotland. The name originally given to this establishment appears to have been *Passeleth*: thus at least is the spelling which occurs in a charter of David I., and from which the present name of Paisley is doubtless derived. Chalmers supposes Passeleth to be derived from the British *Pasgel-laith* (signifying moist pasture-land); but a different etymology is given by a contributor to the 'New Statistical Account of Scotland,' who is of opinion that it comes from the Saxon *Legh* or *Leg* (valley) and *Pais* (peace) or Pass (pass). It was munificently endowed by the descendants of the founder with lands and other property. In 1219 Pope Honorius issued a bull raising the priory to an abbacy, and thereby rendering it independent of the bishop of the diocese. In the reign of Robert III. the abbot and monks were incorporated by royal charter, and thenceforward held their possessions under the crown in free regality, until the suppression of the monasteries in 1535-36, when all the revenue and privileges were resigned in favour of Lord Claud Hamilton, third son of James duke of Chatelherault, the then governor of Scotland, from whose descendants they passed to Lord Cochrane of Paisley and Dundonald. With the growth of the monastery there arose a small town on the opposite bank of the Cart, which James IV., in 1488, erected into a free burgh of barony, under the superiority of George Schaw, the abbot of Paisley. In 1658 the family of Dundonald resigned their right of superiority in favour of the Protector, which act of alienation was confirmed by a charter of Charles II. granted in 1665; but shortly after (1692) that family again acquired the 'lordship of erection' from the crown, which in 1726, by contract of sale, they resigned in favour of the magistrates and council of the burgh. It appears however that the Dundonald family, though no longer possessing any superiority over the burgh of Paisley, were sole proprietors of the lands in the vicinity of the Abbey till the year 1764, when they were bought by the marquis of Abercorn. It is upon these lands that the new town of Paisley has, since 1779, been erected.

The town of Paisley, in the early part of the last century, was solely on the west bank of the river, and it then consisted merely of one principal street and a few straggling lanes. It is now the third town of Scotland in population and commercial importance. The houses are far less handsome than those either of Edinburgh or Glasgow. Low thatched roofs are not uncommon even in some of the principal streets, particularly in the old town, but they are diminishing in number every year. Most of the streets and shops are lighted with gas. The water is indifferent in quality, and the supply has been, at least till very recently, very inadequate. Most of the inhabitants are obliged to purchase water which is filtered from the Clyde or drawn from springs in the neighbourhood. An unsuccessful attempt was made in 1825 to establish a water company. Since that time a capital of 40,000*l.* has been subscribed, and an act of parliament obtained for intercepting the drainage of about 1600 acres on the north-western side of the Gleniffer Braes, and two reservoirs, calculated to contain 50,000,000 cubic feet of water, were, in 1837, in the course of formation, and the entire work was expected to be completed in two years. In the years 1835 and 1836 there fell at Paisley 35 inches and 44·2 inches of rain respectively.

The nave of the old abbey church is all that remains of the antient monastery. It was carefully repaired in the latter part of the last century, and is now used as a parish-church. The style is chiefly Gothic. No part is supposed to be earlier than the middle of the fourteenth century, as in the year 1307, during the wars of the Succession, the monastery is stated to have been almost wholly destroyed by the English. The abbey of Paisley was the family burial-place of the Stewarts, before their accession to the Scottish throne, and since then Robert III. and Euphemia, the wife of Robert II., were interred here. The registry or chartulary of the abbey was published by the Glasgow Maitland Club in 1832. The other churches of the establishment are, the High Church (built in 1756), the Middle Church (1781), and St. George's (1819), the ministers of which receive 300*l.* per annum each. Besides these, there are the Gaelic chapel and a great many other places of worship. Paisley is a presbytery within the synod of Glasgow and Ayr. The burgh and new town are united by three stone bridges, each of two arches. Between two of these, the old and Sneddon bridges, and on the western bank, is situated the castle or county-hall, a fine stone-building erected in 1818, and comprising a court-house, council-chamber, and other offices, a debtor's prison, another for criminals, together with a bridewell and chapel. The police of the town and suburbs is regulated by an act passed in 1806.

Under the act 3 & 4 Will. IV., cap. 77, the magistracy consists of sixteen councillors, including a provost, four bailies, and a treasurer, one-third of whom retire from office annually. The antient boundaries of the burgh are far more restricted than the present parliamentary and municipal boundaries, which include about six square miles, and comprise a large agricultural district. The property of the corporation, in 1833, was estimated at 59,125*l.* The income during the same year was 3843*l.*, and the expenditure 3778*l.* The debts of the corporation, which in 1802 amounted to 15,000*l.*, had increased in 1833 to 33,000*l.* This increase is attributed to the outlay attending the many public works undertaken during the intervening period. Among the earlier works undertaken by the corporation is the improvement of the navigation of the Cart, under a local act passed in the year 1787, authorising the council to levy tonnage dues for that purpose. The bed of the river was considerably deepened, except near Inchinnan Bridge, where it was deemed advisable to connect the parts of the river above and below that bridge by means of a canal which crosses the turnpike road leading from Greenock to Glasgow, and which was completed in 1791. The Cart is now navigable up to the town for vessels of from 50 to 60 tons burthen. The Glasgow, Paisley, and Ardrossan Canal, the cost of which already amounts to 130,000*l.*, but which as yet does not extend in a westerly direction beyond the populous village of Johnstone, crosses the Cart water by an aqueduct bridge on the southern side of the town. A railway extends from the town to a station on the left bank of the Clyde, a little above the mouth of the Cart; and an act of parliament has lately been obtained for constructing a branch of the Forth and Clyde Canal to terminate nearly opposite to this station.

In 1707 the principal articles made in the town were coarse linen, chequered cloths, and Bengals, to which succeeded chequered linen handkerchiefs, and goods of a lighter texture, such as lawns. About 1725 the machinery for making white sewing or ounce thread was introduced from Holland. About 1760 the manufacture of silk gauze was introduced upon the plan practised by the Spitalfields houses, and, during the greater part of the following thirty years, was carried on upon a very extensive scale. The competition between the London and Paisley houses obliged many of the former to relinquish altogether the manufacture of this article. Others removed their establishments to Scotland. The reduction in the cost of cotton goods, consequent upon the invention of Arkwright's spinning-machinery, lessened the demand for silken fabrics, the manufacture of which at Paisley has since then greatly declined.

In 1784, when the linen trade was more prosperous than it has ever been, either before or since, the value of the manufactures produced at Paisley, consisting of silk and linen gauze, lawns, and white sewing thread, was estimated at 579,185*l.*; their value in 1720 was 660,385*l.* Since 1825 a great number of hands have been employed in the manufacture of crape dresses, and damask and embroidered shawls, in imitation of those imported from China. The gross amount of the shawls sold in 1834 was estimated at one million sterling, which was less than in some of the preceding years. Many of the principal establishments of the town are now exclusively engaged in the various branches of the cotton manufacture, among which the muslin branch may be particularly mentioned as that of which Paisley is regarded as the chief seat. A considerable portion of the yarn used in making the finer qualities of muslins is imported from Lancashire. The number of looms in the town in 1837 was ascertained to be about 6000, of which 300 were worked by Glasgow houses. Besides these, about 2000 looms were employed in the country by Paisley capital. The total number of weavers at the same time was 6040. There are also a large iron and three brass founderies, one tan-work, three breweries, three distilleries, one large soap-work, seven extensive bleach-fields, one large silk-throwing mill, &c.

Since the passing of the Scotch Reform Act in 1832, Paisley has returned one member to the British parliament. The boundaries of the parliamentary borough comprise four parishes, whose aggregate population, in 1831, was 57,466, and was distributed among 12,308 families, of whom nineteen-twentieths were employed in trade and manufactures. These parishes were, Paisley Abbey (population 26,006), High Church (14,621), Low Church (6955), Middle Church (9884), which, with five others, constitute what, prior to 1736, was called the parish of Paisley. The new town and suburbs of Paisley and Johnstone, which contain respectively 14,739 and 5617 inhabitants, are included in the return of Paisley Abbey parish. The other three parishes, and these only, are within the corporate liberties. A considerable portion of the inhabitants are Irish, whose immigration materially contributed to the increase of the population during the ten years preceding 1831. This increase amounted to 5032 persons in the three corporate parishes, and 5431 persons in the new town. The local taxes levied within the corporate liberties amount, upon an average of ten years, to 3239*l.* per annum, of which the sum of 2096*l.* is raised on account of the poor. From these taxes the inhabitants of the new town are entirely exempted, as well as from certain charges paid by those who carry on business 'within the burgh.' Although Renfrew is the county town, Paisley has long been the seat of the sheriff's or county court. In 1815 an additional sheriff's court was established at Greenock, and since then the county has been divided into two districts, called the upper and lower wards, the former of which is annexed to the court of Paisley.

There is a weekly market on Thursday, and four fairs, each of three days' duration, which are held in February, May, August, and November. The market and two of the fairs were originally established by charter of Charles II., granted in 1665.

In 1834 there were three parochial and fourteen non-parochial schools in the parish of Middle Church. The greatest number of children which attended the fourteen non-parochial schools during the half year ending with Lady-day, 1834, was 517 boys and 396 girls; the least number during the same period was 425 boys and 338 girls. In High Church parish, where there were no parochial schools, but the same number (fourteen) of non-parochial, the greatest number of children was 888 boys and 751 girls, and the least number 685 boys and 493 girls. One of these was a charity school, wherein 150 day and 100 evening pupils were taught gratuitously. In Low Church parish there was a burgh school. The other schools in this parish, six in number, none of which were parochial, were attended by 555 children, including evening classes. In Paisley Abbey parish there were thirty-one schools, entirely non-parochial. The greatest number of attendances in the half year was 1268 boys, 782 girls; the least number is not stated. In a district of the parish of High Church, containing a population of 1047 persons, there were 46 children between the ages of 5 and 10 who could not read and were not at school; 96 between the ages of 10 and 15 who could not write; 18 above the age of 15 who could neither read nor write: and there were 96 children at school. The above returns do not include Sunday-schools, which were attended by more than 1500 children. The number in 1836 was 4198. (*New. Stat. Acc.*) It was remarked by the Commissioners, from whose Report these numbers are taken, that of the families employed in factories, a greater proportion of the children were attending school than of the families of weavers and labourers. Since the date of the Commissioners' Report, an infant-school has been opened, an endowed school has been established, and a government grant of 700*l.*, augmented by the subscriptions of the inhabitants, has afforded the means of erecting three new school-rooms and enlarging an old one. About three years since, an association was formed for the purpose of instituting a school for the middle and higher classes, to be called the 'Paisley Academy.' There are within the town 45 friendly societies, numbering from 120 to 500 members each, and two of which are supported and conducted exclusively by females. These societies upon the whole are stated to have succeeded remarkably well. The 'Paisley Provident Bank' was established in 1815. Its receipts for the year ending October 30, 1836, amounted to 4520*l.* There is a public dispensary, an infirmary, a mechanics' institution, several subscription libraries, &c.

(*Reports on Scotch Municipalities*, 1836; *Abstract of Report on the state of Education in Scotland*, 1837, xlvii., p. 628-31, and other *Parliamentary Papers*; Chalmers's *Caledonia*; Camden's *Britannia*; Pennant's *Tour in Scotland*; Wilson's *Agricultural Survey of Renfrewshire*, 1812; Crawford's *Renfrewshire*, edited by Robertson, 4to., Paisley, 1818; *New Statistical Account of Scotland*; &c.)

PAL-AIR. [HINDUSTAN, vol. xii., p. 208.]

PALACE, a word adopted into all European languages from the Latin *Palatium*, the name given by Augustus to his residence on the Mons Palatinus at Rome. In its stricter meaning it is restricted to a royal abode, but is occasionally applied to any sumptuous habitation. In Italy the term Palazzo, taken by itself, is used for any large mansion or nobleman's house; and palaces of this class constitute, after churches, the principal architectural features of Genoa, Florence, Rome, Milan, Vicenza, Venice, and other cities, to which they impart an air of grandeur which is wanting in the street architecture of this country; for in spite of all other defects and the bad taste they frequently display, they generally possess the redeeming quality of dignity. Our own metropolis, on the contrary, possesses scarcely half a dozen private mansions that have any pretensions to external nobleness of style. In fact the most palazzo-like buildings we have are one or two of our modern club-houses, more especially the new Reform Club-house, which eclipses all the previously erected ones. Neither are any of our royal palaces, with the single exception of Windsor, stamped by architectural magnificence; both in extent and style they are surpassed by several of the country-seats of our nobility. St. James's Palace is remarkable only for its size and its uncouth appearance. Considered as a work of architecture Buckingham Palace is absolutely discreditable to the present age, its sole characteristics being excessive littleness of manner, and feebleness and triviality of style; whereas, if not remarkable for beauty, Jones's intended palace at Whitehall would at all events have been a pile of imposing dignity. Kensington Palace is merely a respectable mass of brick buildings, and Wren's edifice at Hampton Court is no more than a lumpish piece of formality, destitute of dignity and elegance.

In fact, there are throughout the whole of Europe very few royal palaces, whatever may be their magnitude, at all distinguished by superior architectural taste. In the French capital, it is only the eastern façade of the Louvre, the river front, and the inner court which can lay claim to beauty or richness, the Tuileries being only a mass of quaint grotesqueness. The Vatican at Rome is merely a huge irregular pile, and Versailles and the Escurial, notwithstanding the millions they cost, both monuments of exceedingly bad taste. Though far from beautiful, the royal palace at Madrid, begun in 1737, from the designs of Giambattista Sachetti, an Italian architect, is a stately and regular pile, it being 470 feet square, and 100 in height, but the effect such a mass would otherwise produce is greatly impaired by the number of mezzanines. The same remark applies to the celebrated palace erected by the king of Naples, about the middle of the last century, at Caserta, and of which Vanvitelli was the architect. This building is certainly characterised by magnitude, for it extends 731 feet from east to west, and 569 from north to south; yet in either grandeur of conception or majesty of style there is very little, certainly not enough to reconcile us to the principal execution of so very indifferent a design. The royal palace at Stockholm is a stately edifice in the Italian style, although the original design, by Count Tessin, was considerably curtailed. The original imperial winter-palace at St. Petersburg was a vast pile erected by the Italian architect Rastrelli in the reign of the empress Elizabeth, of most imposing aspect towards the quay of the Neva, but exceedingly heavy and grotesque as to style. This structure, or at least the chief portion, was destroyed by fire in the beginning of 1838, but has since been rebuilt, though we do not know whether according to an entirely fresh design. The Neue Residenz and Königsbau at Munich have already been spoken of elsewhere. [MUNICH.]

Enormous as have been the sums expended upon many of these edifices, every one of them falls very short of the ideal of a royal palace, in which, if anywhere, not only all the luxury and pomp of architecture, but a certain colossal dignity of aspect should present itself. This can never be accomplished where stories above stories are allowed to display themselves externally. That is but a vulgar species of architectural grandeur which is produced by a numerical multiplication of little parts and features. All the rooms required for the accommodation of an extensive household should be turned towards inner courts, and the whole exterior, having only a single range of lofty windows above the ground floor, should be left for the unrestrained display of architecture, and sculpture upon a noble scale, without any intermixture of littleness. By such a disposition, too, convenience would perhaps be found far better consulted than at present, because, while all the apartments for official and state receptions and court entertainments would be connected together, the whole of the vast number of subordinate rooms required in such a habitation would be concentrated within the general plan, and at the same time might be kept entirely apart, by means of galleries between the outer and inner range, communicating at intervals with lesser vestibules and staircases attached to the suites of lesser rooms and private apartments of every description.

PALÆ'ADES. [TRILOBITES.]

PALÆMON, the generic name for the *Prawns*. [SHRIMPS.]

PALÆMONIANS, or PALÆMO'NIDÆ, Prawn tribe. [SHRIMPS.]

PALÆOGRAPHY. The study of ancient documents, called by modern antiquaries 'Palæography,' is too extensive a subject to be canvassed at length in a work like the present. We content ourselves therefore with pointing out to the student the most eligible works on the subject, and with setting before him as briefly as possible the indices which have been published to the manuscript stores of this and other countries.

An 'Introduction to Bibliography,' by Mr. Hartwell Horne, contains some elementary matter very well adapted for the beginner; it is however principally compiled from some French works on the subject. The splendid volumes recently published by the French historical commission, under the title of 'Elements of Palæography,' may be safely stated to contain every particular that can be wished for; and this work is so luminous in its details, that we need do no more than refer to it for the usual abbreviations employed in the middle ages in every kind of political and ecclesiastical documents. Walther's 'Lexicon Diplomaticum' may also be referred to as a useful work. At the same time we must beg to caution the reader against a book, published some years since, entitled 'A Guide to Court Hand,' by Mr. Wright, which is as full of errors as a book can well be. A certain series of abbreviations are found in all Latin manuscripts, and these have been imitated in type in the works of the late Record Commission. Mr. Black has given a complete list of these abbreviations, with explanations, in the 'Excerpta Historica.'

A great quantity of abbreviations are merely arbitrary, which requires practice and ingenuity before all kinds can be read with any facility; for instance, the capital letter A has been found to represent the following words:—Ab, Abbas, Abs, Actiacus, Actio, Actus, Ad, Ædilis, Ædilitius, Æs, Æternum, Æs, Ager, Agis, Agrippa, Agrippina, Ait, Ala, Albus, Alius, Alter, Amantissimus, Amicus, Amnem, Annus, Annos, Animus, Annus, Ante, Antiochia, Antonius, Apollo, Apponere, Apud, Aqua, Aratrum, Arbitrium, Arbitrium, Argentum, Aristides, Artificialis, Assis, Assignatum, Asses, At, Auctor, Auctoritas, Augusta, Augustalis, Augustus, Aulus, Aurelius, Aurum, Auspicium, Aut, Auxilium, Avis, Avus. The edition of Gaius by Goeschen, Berlin, 1824, contains a complete alphabetical list of all the sigla or abbreviations which are used in the Verona MS. They are very numerous; and as one abbreviation often represents a great many different words, it is only from the context that the meaning in any given instance can be ascertained. [GAIUS.]

We now proceed to present the reader with the principal desiderata in this branch of literature, a list of catalogues of manuscripts in the libraries of this country and the Continent.

The British Museum.—In point of real interest and value, the collection of manuscripts preserved in this noble establishment surpasses every other.

1. 'A Catalogue of the Cottonian MSS. in the British Museum,' fol., Lond., 1802.

This collection forms the most valuable portion of the Museum's stores; but it is so well known, that any further notice of it here is unnecessary.

2. 'A Catalogue of the Harleian MSS. in the British Museum,' 4 vols. fol., 1808-12.

Mr. Halliwell says that 'the first portion of this catalogue is very well compiled, but the third volume is full of imperfections and errors:' the fourth volume contains an excellent index by Mr. Horne. This collection includes numerous MSS. of every class.

3. 'A Catalogue of the additional Manuscripts in the British Museum,' by S. Ayscough, 2 vols. 4to., Lond., 1782.

A new catalogue of these MSS. is in preparation.

4. 'A Catalogue of the Lansdowne MSS. in the British Museum,' fol., London, 1819.

The most remarkable and valuable portion of this collection is the Burghley Papers, which fill 121 folio volumes, and comprise a multitude of state documents, together with the political and miscellaneous correspondence of Lord Burghley, extending throughout the long reign of Queen Elizabeth. The collection also contains the papers of Dr. White Kennett, bishop of Peterborough; and a large portion of those of Sir Julius Cæsar, judge of the Admiralty in Queen Elizabeth's time. Bishop Kennett's papers relate to the ecclesiastical history of England and to the biography of the more eminent of the clergy, with materials for a detailed history of the diocese of Peterborough or of places therein. The papers of Sir Julius Cæsar furnish most ample information respecting the finances of the reigns in which he was officially employed, and contain many curious articles on the privileges and practice of the courts of Admiralty, Requests, Star Chamber, and Exchequer. Exclusive of these larger series, the Lansdowne manuscripts have many volumes of great interest; among them a volume of letters by royal, noble, and eminent persons in Great Britain, from the reign of Henry VI. to that of George III.; two volumes of letters written by foreign sovereign princes and other distinguished strangers during the sixteenth, seventeenth, and eighteenth centuries; three volumes of letters to Henry Cromwell, when chief governor of Ireland; eleven volumes of the papers of Dr. John Pell, envoy from Oliver Cromwell to the Protestant cantons of Switzerland; five volumes of Sir Paul Rycaut's papers; and three volumes containing the correspondence of the Earl of Melfort during his negotiations at Rome in the year 1690. Neither would it be right to pass over without notice numerous monastic chartularies and registers; among them, registers of the priory of St. John of Jerusalem, of Harewood Priory, of Lundæ Priory, of the monastery of Gerondon, of Malmesbury Abbey, and of the Abbey of Melsa; two registers of Chertsey Abbey, and one of the prebendal church of Edyndon in Wiltshire.

5. 'A Catalogue of the MSS. of Francis Hargrave, now deposited in the British Museum,' 4to, London, 1818.

These MSS. relate almost exclusively to law; they consist of year books, reports, readings on various statutes, treatises on the authority and jurisdiction of the several courts of law and equity, collections of cases and opinions, collections respecting the customs and privileges of London and other places, and tracts and dissertations on numerous points and matters of law, with a few historical, political, and miscellaneous papers and letters.

6. 'A Catalogue of the MSS. in the Royal Library in the British Museum,' 4to., London, 1734.

This contains the MSS. of the old Royal Library at St.

James's, and possesses curious articles in almost every branch of literature.

7. 'Catalogus Codicum Manuscriptorum Bibliothecæ Burneianæ,' fol., London, 1839.

It contains about 520 volumes of manuscripts; among which are five manuscripts of the gospels in the original Greek, of the eleventh, thirteenth, and fourteenth centuries; copies of commentaries upon the scriptures, both in Greek and Latin; and manuscripts of the didactic and controversial works of several of the Greek and Latin fathers. But the most important portion of the collection consists of manuscripts of the classical authors. Of these, the celebrated manuscript of the 'Iliad' of Homer, formerly belonging to Mr. Charles Townley, is justly entitled to the first place in estimation. Though probably not older than the latter part of the thirteenth century, it is one of the earliest complete manuscripts of the 'Iliad,' and is particularly valuable, both on account of the correctness of its text and also of the copious scholia with which it is illustrated. Two copies of the Greek orators likewise deserve especial notice; one of them, written upon vellum, is perhaps the most important manuscript extant of these authors; it yields many valuable readings, and supplies, besides smaller lacunæ, portions of Isæus, Lycurgus, and Dinarchus. There is also an important manuscript of the Geography of Ptolemy, with maps, in the original Greek; a volume containing the twenty comedies of Plautus, a portion of which has been collated by Mr. Hildyard for his editions of the 'Menaechmi' and 'Aulularia;' a beautiful manuscript of Callimachus; and a very fine copy of the mathematical collections of Pappus Alexandrinus, which formerly belonged to Baroci. [PAPPUS.]

8. 'A Catalogue of the Arundel Manuscripts in the British Museum,' fol., London, 1834.

This collection is rich in materials for the history of our own country and language, having no less than seven copies of the 'Historia Britonum' of Geoffry of Monmouth, copies of the histories or annals of Henry of Huntingdon, Ralph Higden, Roger de Hoveden, William of Malmesbury, Nicolas Trivet, and others. It has also a recent but unique manuscript of Ingulph's 'Descriptio Abbatiæ Croylandensis,' and a volume of letters and other documents relative to the divorce of Henry VIII. from Katherine of Aragon, some of which are original. There are also chartularies of the Abbey of St. Alban's, of the hospital without the Southgate at Bury St. Edmunds, of the monastery of St. John at Colchester, of the abbeys of Sibton and Tinterne, of the monasteries of St. Austin and Christ-Church, Canterbury; of the convent of St. Mary and St. Margaret, Dartford; of the abbey of Glastonbury, and of that of Newenham in Devonshire. We may also mention a curious volume entitled 'Ayenbyte of Inwyt,' composed A.D. 1340, by a monk of Canterbury, in the Kentish dialect of that period, and which will shortly be published by Mr. Wright; and a large number of volumes on jurisprudence, comprising the 'Digests and Codex of Justinian, the 'Decretum' of Gratian, and the 'Decretals' of Gregory XII. and Boniface VIII., with numerous glosses, commentaries, dissertations upon texts, summaries, and collections of decisions, cases, and opinions.

9. 'Catalogue of the additional MSS. in the British Museum,' 24 vols. fol.

These are deposited for general use in the reading-room of the Museum.

Other Libraries in Great Britain.—We possess the following printed catalogues:—

1. 'Catalogi Librorum Manuscriptorum Angliæ et Hiberniæ, in unum collecti, cum indice alphabetico,' fol., Oxon, 1697.

The first volume contains a catalogue of the Bodleian and Ashmolean manuscripts; the second, those of the colleges of Oxford and Cambridge; the third, of various libraries in England; and the fourth, of Irish libraries. 'A Short Account of some MSS. in the English Libraries which contain parts of the Corpus Juris by Dr. Hach, Jun.,' was printed in the 'Zeitschrift fur Geschichtliche Rechtswissenschaft,' vol. v., 1821.

2. 'Catalogus Librorum Manuscriptorum Col. Corp. Christi. Cantab.,' 4to, Cantab, 1777.

3. 'Catalogus Codicum Manuscriptorum Eccles. Cathed. Dunelmensis,' fol, Dun., 1824.

4. 'A Catalogue of the Manuscripts in the Library of the Society of Antiquaries,' by Sir H. Ellis, 4to., London, 1816.

5. 'A Catalogue of the miscellaneous Manuscripts in the Library of the Royal Society,' by J. O. Halliwell, Esq., 8vo., London, 1840.

6. 'A Catalogue of the Archiepiscopal MSS. preserved in the Library of Lambeth Palace,' by Todd, fol., Lond., 1812.

7. 'Catalogus sive Notitia Manuscriptorum, qui à G. D. Clarke, comparati in Bibliotheca Bodleiana adservantur,' 4to., Oxon, 1812.

Principally classical.

8. 'Catalogus Codicum MSS. et Impressorum cum notis Manuscriptis, olim D'Orvilliani,' 4to., Oxon, 1806.

This collection is in the Bodleian Library.

9. 'A minute Catalogue of each particular Manuscript contained in Wood's Collection at Oxford,' 8vo., Oxf., 1761.

We must here notice the splendid library of Sir Thomas Phillips, Bart., at Middle Hill, Worcestershire, who possesses the largest known private collection of manuscripts and charters, some of which are of the greatest rarity and importance. A slight catalogue of a portion of these has been privately printed by the learned possessor at his own private press, and this has been copied into Haenel's compilation. The Earl of Leicester at Holkham possesses a valuable collection, of which a brief account has appeared in the second volume of the 'Transactions of the Royal Society of Literature.' Dr. O'Conor prepared a catalogue of the MSS. at Stowe, the seat of the Duke of Buckingham, which was privately printed in 1818, in two volumes 4to. Considerable numbers of MSS. are likewise preserved in the Glasgow University library, Lincoln Cathedral, and in various places, by far too numerous for us to attempt even a bare outline; we give however a slight list of the documents preserved in the Tower of London, with the hope that it will prove useful to the antiquary and historian:—

1. Negociationes et fœdera cum principibus extraneis.
2. Gentis hujus atque populi præclaræ res gestæ in Gallia aliisque regionibus transmarinis.
3. Homagium et servitia, in quibus Scotia ab Anglia pendet.
4. Hiberniæ in legibus et dominiis constitutio.
5. Dominium marium Britannicorum, Gallos Batavosque a Piscatione in prædictis maribus prohibens, nisi venia prius a Regibus Angliæ impetrata, generali præscriptione comprobatum.
6. De rebus Walliæ, ac etiam compotis reditium Principis Walliæ.
7. Quæ res potissimum ad commoda spectarunt Insulæ Monaviæ, Insularum Cæsariæ et Sarniæ, Vasconiæ, Caleti, Burdegalæ, aliarumque Galliæ partium, quamdiu sub Anglorum ditione tenerentur.
8. Jus linealis successionis, quo reges Angliæ regnum Galliarum vendicant.
9. Tenuræ terrarum in Anglia extentæ, sive metationes maneriorum, et inquisitiones post mortem, ostendentes quas terras defunctus tenuit, quis proximus hæres, et quot annos habuit.
10. Libertates atque privilegia concessa urbibus oppidisque corporatis, vel personis privatis, uti letæ, mercata, feriæ, communia pasturæ, waivia, extrahuræ, felonum bona, pontagium, &c., et quicquid aliud ad fiscum regium perventurum est, vel ex eo proventurum.
11. Coronationes regum Angliæ, cum particularibus tenuris et clameis singulorum qui dictis coronationibus inservire tenentur, una cum ordine et ratione processionis.
12. Brevia, placita, processus spectantes ad supremam Cancellariæ curiam, ad curias Banci Regii, Communium Placitorum, Scaccarii, et justitiariorum itinerantium.
13. Concessiones regiæ custodiæ comitatuum, urbium, oppidorum, et portuum. Conscriptiones et delectus copiarum tam marinarum quam terrestrium in regni propugnationem.
14. Fundationes abbatiarum et prioratuum, aliarumque ædium religiosarum in Anglia, Wallia, Gallia, et Hibernia, una cum singularum ordinibus, terrisque et possessionibus iisdem donatis.
15. Metæ et termini forestarum in Anglia cum clameis forestariorum.
16. Inspeximus et irrotulationes chartarum et munimentorum, tam ante quam post Conquestum concessorum.
17. Irrotulantes multarum evidentiarum et contractuum inter personas invicem datorum.
18. Concessiones et constitutiones plurimorum superioris ordinis officiorum in regnis Angliæ et Hiberniæ.

19. Officium Marescalli Angliæ.
20. Placita et creationes procerum.
21. Paparum bullæ autographæ.
22. Bullæ taxationis Papalis, continentes valorem singulorum beneficiorum in Anglia.
23. Regalia regum Angliæ in rebus ecclesiasticis accurate descripta.
24. Quamplurima records præcipue spectantia ad rem pecuniariam, nummariam, feodalem, classicam, ad militiam, ad bellum, et regni defensionem per multa sæcula.
25. Auxilia et subsidia Regi concessa.
26. Chartæ et confirmationes libertatum et privilegiorum collegiorum et civitatis Oxoniensium.
27. Præsentationes factæ a Domino Rege ad ecclesias, præbendas, et capellas.
28. Tabula rotulorum parliamenti hodie extantium in officio custodis recordorum in turri Londinensi, ab an. 5 Edw. III. ad an. 22 Edw. IV.

The most complete index to the literary stores of the Continent is in Hænel's 'Catalogus Librorum Manuscriptorum qui in Bibliothecis Galliæ, Helvetiæ, Belgii, Britanniæ Magnæ, Hispaniæ, Lusitaniæ asservantur,' published at Leipzig in 1830. To that work we refer the reader, merely observing that the portion containing an account of the manuscripts of this country is very imperfectly and badly executed.

The Age of Manuscripts.—There are several criteria whereby we are enabled to judge of the age of manuscripts, but it requires much practice before a really correct opinion in these particulars can be given; and so much depends upon a personal examination of a large number of all ages, that no infallible rules can be given on the subject. We refer the student to Wailly's 'Paléographie.'

The books principally made use of in the preceding slight sketch are—1, *The Appendix to the Last Report of the Record Commissioners*; 2, Halliwell's *Hints to Novices in Manuscript Literature*; 3, *Élémens de Paléographie*, 2 vols.; 4, Casley's *Catalogue of Manuscripts in the King's Library*. But the most accessible work on this subject is *A Treatise on Bibliography*, by the Rev. Thomas Hartwell Horne, the author of the valuable 'Index' to the *Harleian Catalogue*, which contains much useful information for the general reader.

PALÆ'OMYS, Professor Kaup's name for an extinct genus of Rodents from the Epplesheim sand.

Example, *Palæomys castoroides* (Kaup).

PALÆONISCUS, a remarkable genus of Heterocercal fossil fishes, constituted by M. Agassiz, and included by him in the first family (Lepidoidei) of his great order of Ganoidean fishes. Its place in this family will appear from the following synopsis of the Lepidoidei:—

A. Body elongated, fusiform, upper lobe of the tail vertebrated, and longer than the lower lobe.
- *Acanthodes.*
- *Catopterus.*
- *Amblypterus.*
- *Palæoniscus.*
- *Cheirolepis.*

B. Body flat, broad.
1. Upper lobe of the tail vertebrated.
   - *Platysomus.*
   - *Gyrolepis.*
2. Tail regular (the lobes nearly equal).
   - *Tetragonolepis.*
   - *Dapedius.*

C. Body elongated, fusiform, tail forked or rounded.
- *Semionotus, Lepidotus, Pholidophorus, Microps, Notagogus.*

The generic character of Palæoniscus is thus given:—

All the fins of moderate size, with small rays on their edges; the dorsal fin opposite the interval of the ventral and anal fins. Scales moderate. In some species the scales are larger, and the body is broader and shorter than in the others; there are always large mesial scales in front of the dorsal and anal fins.

The genus comprehends Palæoniscum and Palæothrissum of Blainville.

The geological interest of this genus is considerable, inasmuch as the numerous species appear to be very definitely distributed in the strata of the Carboniferous and Saliferous systems of Europe and America. The following is the list of species examined by Agassiz, with their localities, and the names of the formations in which they occur:—

1. P. fultus . .	Coal formation	Sunderland (Massachusetts), Westfield (Connecticut).
2. P. Duvernoy .	Coal formation	Munster Appel.
3. P. minutus .	Coal formation	Munster Appel.
4. P. Blainvillii .	Coal formation	Near Autun.
5. P. Voltzii .	Coal formation	Near Autun.
6. P. angustus .	Coal formation	Munster Appel.
7. P. Vratislavensis	Rotheliegende	Ruppersdorf in Bohemia.
8. P. lepidurus .	Rothelliegende	Scharfeneck in Co. Glatz.
9. P. Freieslebeni	Zechstein . .	Mansfield, Hesse, Eisleben, &c.
10. P. magnus .	Zechstein . .	Mansfield.
11. P. macropomus	Zechstein . .	Mansfield.
12. P. elegans .	Lower part of Magnesian Limestone	East Thickley in Durham.
13. P. Robisoni .	Carbonif. limestone	Burdiehouse (near Edinburgh).
14. P. striolatus .	Carb. limest.	Burdiehouse.
15. P. ornatissimus	Carb. limest.	Burntisland (Fife).
16. P. comtus . .	Magnes. limest.	Durham.
17. P. glaphyrus .	Magnes. limest.	Durham.
18. P. macrophthalmus	Magnes. limest.	Durham.
19. P. longissimus	Magnes. limest.	Durham.
20. P. carinatus .	Carbonif. series	Newhaven (near Edinburgh).

The researches of Agassiz have given a simple and beautiful generalization of the distribution of these species; the scales of the Palæonisci, which abound in the coal formation, are almost universally smooth; those of the species which belong to the magnesian limestone are almost universally striated or sculptured. We find a few exceptions to this rule, as at Burdiehouse, and at Ardwick near Manchester, but it rests on a considerable number of coincidences. It is an unexpected result of Agassiz's critical inquiry into the forms of fossil fishes, that the Palæonisci of the English magnesian limestone are not identical with those of the zechstein of Germany, notwithstanding the supposed contemporaneity of the rocks.

PALÆORNIS. [PSITTACIDÆ.]

PALÆOSAU'RUS, the name given by Dr. Riley and Mr. Samuel Stutchbury to a genus of fossil Saurians discovered in the magnesian conglomerate on Durdham Down, near Bristol (1834).

The conglomerate wherein the Saurian remains were found rests upon the edge of inclined strata of mountain limestone, filling up the irregularities of their surface, and consists of angular fragments of the limestone cemented by a dolomitic paste. The thickness of the deposit where the remains were discovered does not exceed twenty feet.

Three animals were found, two belonging to the genus *Palæosaurus*, and the other to a genus named by them *Thecodontosaurus*. [THECODONTOSAURUS.]

Generic Character of Palæosaurus.—Teeth compressed laterally, and finely serrated at right angles to the axis, differing from those of all the known Saurians.

Species.—The teeth in the possession of the authors exhibit minor marked characters, and they have accordingly considered them as belonging to two species, *Palæosaurus cylindrodon* and *P. Platyodon*. (*Geol. Proc.*, 1836.)

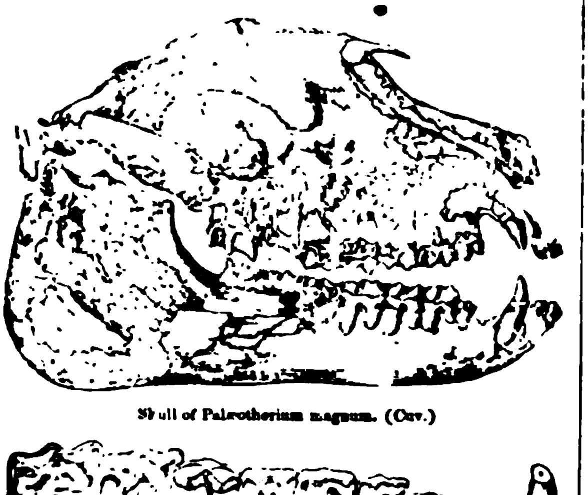
PALÆOTHE'RIUM, Cuvier's name for an extinct genus of Pachydermatous *Herbivora* discovered in the gypsum beds at Paris in company with *Anoplotherium*. [ANOPLOTHERIUM.] The discovery and definition of these and other Pachydermic forms, now utterly swept away from the face of the globe, form one of the noblest triumphs of the great French zoologist, who, from confused fragments huddled together pell-mell, separated the different bones, and, so to speak, gradually built up the framework of the lost animals, till their osseous structure and place in the chain of created beings became as well known as those of the animals that dwell upon the earth at the present day.

'It is not easy,' says Dr. Buckland (*Bridgewater Treatise*), 'to find a more eloquent and striking acknowledgment of the regularity and constancy of the systematic contrivances that pervade the animal remains of the fossil world, than is contained in Cuvier's introduction to his account of the bones discovered in the gypsum quarries of the neighbourhood of Paris. It affords, to persons unacquainted with the modern method of conducting physical researches, an example of the kind of evidence on which we found our conclusions as to the form, character, and habits of extinct creatures that are known only through the medium of their fossil remains.'

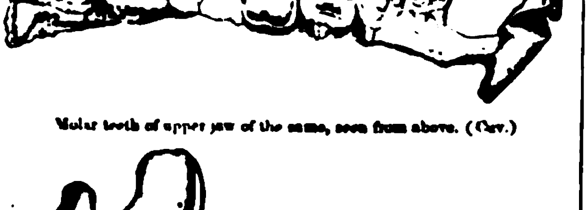
The striking passage alluded to by Dr. Buckland, after stating by what slow degrees the Parisian cabinets had been filled with innumerable fragments of bones of unknown animals from the quarries of Montmartre, thus describes the mode in which Cuvier worked out the task of reconstructing their skeletons. He had already ascertained that there were numerous species belonging to many genera; and we shall now let this prince of comparative anatomists speak in his own person. 'I at length found myself, as if placed in a charnel-house, surrounded by mutilated fragments of many hundred skeletons of more than twenty kinds of animals piled confusedly around me: the task assigned to me was to restore them all to their original position. At the voice of comparative anatomy every bone and fragment of a bone resumed its place. I cannot find words to express the pleasure I experienced in seeing, when I discovered one character, how all the consequences which I predicted from it were successively confirmed. The feet accorded with the characters announced by the teeth; the teeth were in harmony with those previously indicated by the feet. The bones of the legs and thighs and every connecting portion of the extremities were seen joined together precisely as I had arranged them before my conjectures were verified by the discovery of the parts entire. Each species was in short reconstructed from a single unit of its component elements.'

Generic Character of Palæotherium.—Dental formula: Incisors, $\frac{6}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{7-7}{7-7}$ = 44. Three toes on each foot. A short fleshy proboscis, for the attachment of the muscles of which the bones of the nose were shortened, leaving below them a deep notch.

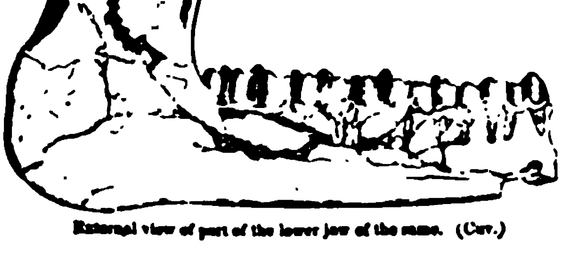
The molar teeth bear considerable resemblance to those of the Rhinoceros: in the structure of that part of the skull destined to support the short proboscis and the feet, the animal closely approached the Tapirs.



Skull of Palæotherium magnum. (Cuv.)



Molar teeth of upper jaw of the same, seen from above. (Cuv.)



External view of part of the lower jaw of the same. (Cuv.)

The species are numerous, and the following have been named:—*Palæotherium magnum* (gypsum of Montmartre), *P. medium* (gypsum of Montmartre, osseous breccia, Sète, &c.), *P. crassum*, *P. latum*, *P. curtum*, *P. minus*, *P. minimum*, *P. indeterminatum* (gypsum of Montmartre), *P. Aurelianense* (lacustrine formation of Orleans, Argenton, &c.), *P. Isselanum* (tertiary, Issel), *P. Velaunum* (tertiary, Puy-en-Velay).

Remains of *Palæotheria* have also been found in the tertiary formation near Rome, in the department of the Gironde, Provence, &c.

Mr. S. P. Pratt discovered, in the lower and marly beds of the quarries of Binstead in the Isle of Wight, which belong to the lower fresh-water formation, a tooth of an *Anoplotherium* and two teeth of the genus *Palæotherium*, animals characteristic of strata of the same age in the Paris basin. The remains found by Mr. Pratt were accompanied not only by several other fragments of the bones of *Pachyderms* (chiefly in a rolled and injured state), but also, in his opinion, by the jaw of a new species of *Ruminants*, apparently closely allied to the genus *Moschus*. From the occurrence of the latter fossil, Mr. Pratt infers that a race of animals existed at this geological epoch whose habits required that the surface of the earth should have been in a very different state from that which it has been supposed to have presented, in consequence of the frequent discovery of the remains of animals who lived almost entirely in marshes. (*Geol. Proc.*, 1830.)

Professor Owen, in his paper on *Chæropotamus* (1838), offered some remarks on the jaw discovered by Mr. Pratt in the Binstead quarries in 1830, and considered by him to be allied to the genus Moschus.* On comparing the jaw with the corresponding part of the *Moschus moschiferus*, which it resembles in size, Mr. Owen found that in the fossil the grinders are relatively broader, that the last molar has the third or posterior tubercle divided by a longitudinal fissure, that the grinding surface is less oblique, and that the coronoid process differs from that of the Moschus and other ruminants, but strongly bespeaks an affinity with the Pachydermata.

Professor Owen further remarked, that among the genera of the Paris basin established by Cuvier, the Dichobune exhibits characters which connect the Pachydermata with the Ruminantia, and thus exhibits another of those extraordinary unions of characters which in existing Mammals belong to distinct orders. In the Dichobune the posterior molars begin to exhibit a double series of cusps, of which the external present the crescentic form, so that the teeth of the *Dichobune murina* might be mistaken for those of true Ruminantia. In the lower jaw of the Dichobune the antepenultimate and the penultimate grinders have two pairs of cusps, and the last grinder three pairs, of which the posterior are small and almost blended together, so that when worn down they appear single.

In this respect, as well as in the form of the ascending ramus of the lower jaw, Cuvier states, in the 'Ossemens Fossiles,' that the Dichobune 'prodigiously resembles' the young Musk Deer.

Now with respect to Mr. Pratt's specimen, Professor Owen observed, that there is undoubtedly a close resemblance to the Musk Deer, but the differences are sufficiently great to forbid its being placed among the Ruminantia; while there is a still nearer resemblance between it and the genus Dichobune. The Isle of Wight specimen being somewhat larger than the *D. leporinum*, and the ascending ramus differing in form and approaching that of the true Anoplotheria, Mr. Owen considered that it indicated a new species, which, until the form of the anterior molars and incisors is known, might be referred to the genus Dichobune, under the name of *Dichobune cervinum*. (*Geol. Proc.*)

Geological Position.—The geological place of the extinct genus *Palæotherium* is in the first great fresh-water formation of the Eocene period of Lyell, where it is found with its congeners, of which nearly fifty extinct species were discovered by Cuvier.

Zoological Position, Habits, &c.—The zoological position of the genus appears to be intermediate between the rhinoceros, horse, and tapir. Their habits probably approximated to those of the tapirs. Dr. Buckland is not singular in thinking that these animals lived and died upon the margins of the then existing lakes and rivers. He is also of opinion that their dead carcasses may have been drifted to the bottom in seasons of flood, and that some perhaps retired into the water to die. The species varied greatly in size, some having been as large as a rhinoceros, and others having varied from the size of a horse to that of a hog.

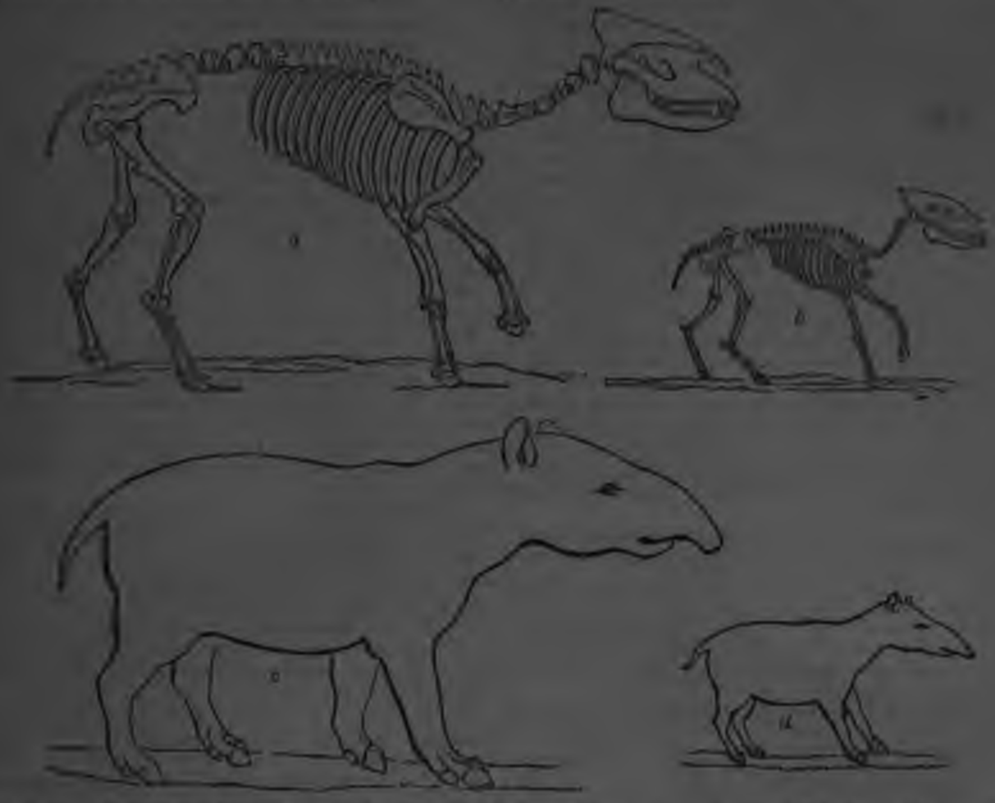
---

* 'Geological Transactions,' Sec. Ser., vol. iii., p. 431.

Examples, *Palæotherium magnum* and *Palæotherium minus*.

Palæotherium magnum.—Size of the skull equalling that of the largest horses.

Palæotherium minus.—Size of the skull smaller than that of the roe (Chevreuil).



a, restored skeleton of Palæotherium Magnum; b, restored skeleton of Palæotherium Minus; c, restored outline of Palæotherium Magnum; d, restored outline of Palæotherium Minus. (Cuv.)

PALÆOZOIC SERIES. The fossiliferous strata of earlier geological date than the carboniferous system, and the mountain limestone, are thus designated in the article ORGANIC REMAINS. One of the greatest impediments to a clear exposition of geological truths, is the difficulty of choosing proper general terms to suit classifications founded on limited researches. The antient terms of Primary, Secondary, and Tertiary Rocks will probably retain their popularity and applicability, because of the simplicity of the truly general idea which they contain in common—*the sequence of geological time*. In characterising and naming the subdivisions of these great groups of rocks, geologists have only partially followed out the same principle; every geological investigation of sufficient extent includes, as a principal point, the discovery of the relative antiquity of the subdivisions of Primary, Secondary, and Tertiary strata, but there is seldom an opportunity to frame a corresponding nomenclature, owing to the circumstance that general names, already and indeed long since proposed and adopted by the great body of geologists, cannot without great inconvenience be changed, even when new discoveries or wider generalizations demand their correction.

The term 'Transition' was applied to a large section of the Primary rocks, or else used to designate them as a separate class, at a time when true characters could by no means be assigned to them. Among Transition rocks, 'Grauwacke' was frequently seen. Hence the term Grauwacke System was commonly used to express a large portion (the upper) of the Primary series of strata.

In progress of rigorous investigation, the absence of organic remains from the gneiss and mica-schist rocks, and the occasional or ordinary presence of them in the grauwacke series, became generally admitted, and hence the convenient classification of Mr. De la Beche of 'Fossiliferous' and 'Non-fossiliferous' Primaries, the former being in fact an equivalent term for 'Transition Strata.' Recent researches into the succession of the fossil plants and animals of these earliest strata have produced very strong evidence for believing that, from the Snowdonian slates, placed by Professor Sedgwick in the lower part of the Cambrian system, to the lower beds of the old red-sandstone (at least), one system of organic life prevails—characterised by the preponderance of corals, such as Catenipora and Favosites, shells of Brachiopoda and Cephalopoda, and crustacea of the trilobitic types. It is true that when separate strata, included within the limits of geological time just stated, are compared in respect of their organic contents, distinctions more or less marked appear (as for example, conspicuously in the strata of the Silurian system), yet these mostly turn on minor differences of some of the analogous forms, and may perhaps have only a local value, as we know to be the case in the instance of the oolitic strata.

On the contrary, if we compare the whole series of organic forms found in these Palæozoic Strata, as they are exhibited in Wales or Cumberland, with the whole series of fossils discovered in the carboniferous system of the north of England or the border of Wales, we find not more than 1, 2, or 3 per cent. of intimately related species. The distinction between the Silurian fossils and those of the mountain limestone is of the same order as that which obtains between the latter series and the fossils of the magnesian limestone. Struck with this fact, Mr. Murchison has suggested for the early groups of strata the title of 'protozoic rocks,' which (beside one chance of ambiguity from the meaning attached in zoology to the word 'Protozoa') seems to assert more than is necessary, perhaps more than is known. We prefer therefore to apply to the same strata the title of Palæozoic, which seems liable to no objection, and which has, we believe, been occasionally employed by Professor Sedgwick.

Supposing, as we think likely, that general terms for stratified rocks, thus formed upon a consideration of their organic contents, which appear to follow a great law of succession, will be preferred to others based on a view of their mineral qualities, which are certainly subject to repetition, there will be no other difficulty in their construction or application than what may be overcome by the progress of investigation. As many systems or combinations of organic forms as are clearly traceable in the stratified crust of the globe, so many corresponding terms (as Palæozoic, Mesozoic, Kainozoic, &c.), may be made, nor will these necessarily require change upon every new discovery. For instance, the term Palæozoic may be retained, though it should be found that the application of it ought to be extended so as to include the carboniferous rocks or even the magnesian limestone ('Zechstein' of Germany). This indeed is not unlikely, for the following reasons. First, it is the opinion of eminent living geologists (Professor Sedgwick, Mr. Murchison, and others) that in strata which correspond in age to the old red-sandstone, there occur groups of organic remains intermediate in forms and combinations between the types of the Silurian and carboniferous æras. Secondly, it is ascertained that a large proportion of the forms of zoophyta, mollusca, and fishes, which appear in magnesian limestone, are extremely analogous to or even identical with some of the more numerous species of the mountain limestone. At present the Palæozoic series of rocks includes the following formations, placed in the order of position, according to the most recent views:—

Old Red-Sandstone.—This in whole or in part is supposed by Mr. Murchison and others to be represented by the calcareous, arenaceous, and argillaceous rocks of North and South Devon, Cornwall, part of Brittany, the Harz, Westphalia; and they prefer to call the series *Devonian*, from the county where it is supposed to be best developed.

Silurian Rocks.—Mr. Murchison ranks these in four formations, viz. Ludlow Rocks, Wenlock Rocks, Caradoc Rocks, Llandeilo Rocks.

Cambrian Rocks.—Professor Sedgwick subdivides them into Plynlymmon Rocks, Bala Limestone, and Snowdon Rocks.

It is supposed, but perhaps has not been perfectly ascertained, that the rocks of Skiddaw, &c., which come next in order below, are deficient of organic remains. May we propose for these and other lower stratified rocks the term 'Hypozoic Series?'

PALÆ'PHATUS. Four Greek writers of this name are mentioned by Suidas, the oldest of whom, an epic poet, a native of Athens, is said to have lived before the Homeric times. Suidas quotes the titles of several of his works, the 'Cosmopoea,' 'The birth of Apollo and Diana,' &c. The second was a native of Paros or Priene, who lived in the time of Artaxerxes Mnemon, and to him Suidas ascribes a work in five books entitled 'Of Things Incredible.' The third Palæphatus was an historian of Abydos, and a great friend of Aristotle. The fourth is called a grammarian of Alexandria by Suidas, and a Peripatetic philosopher by Tzetzes and others; the period in which he lived is not stated. Suidas mentions a work by him, entitled 'Explanation of Things related in Mythology.' This seems to be the work which has come down to us in one book divided into fifty short chapters, under the name of Palæphatus, and which is commonly entitled 'On Things Incredible.' The author explains, according to his fashion, the origin of the mythical fables, such as the Centaurs, Pasiphae, Actæon, &c., to which he attributes an historical foundation disguised or corrupted by ignorance or love of the marvellous. The best edition of the text is that of Fischer, Leipzig, 1789, in which he has given all the passages of antient authors concerning the various writers of the name of Palæphatus. A Latin translation of the work was published at Cambridge, in 1671, and a French translation was published at Lausanne in 1771. There are some other fragments under the name of Palæphatus which have been published with the work above mentioned, one on the invention of the purple colour, and the other on the first discovery of iron. (Vossius, *De Historicis Græcis;* Fabricius, *Bibliotheca Græca.*)

PALÆSTRA (*παλαίστρα*), which properly means a school for wrestling (*παλαίειν*, 'to wrestle,' and *πάλη*, 'wrestling'), was used in several different significations. The word first occurs in Herodotus (vi. 126, 128), who informs us that Clisthenes built at Sicyon a dromos and palæstra, both of which he calls by the general name of gymnasia. At Athens however it appears probable that the palæstræ and gymnasia were distinct places, and that the former were appropriated to the gymnastic exercises of the boys and youths (*παῖδες* and *μειράκια*), while the latter were intended for those of the men. These palæstræ were called by the names either of their founders or of the teachers of gymnastic exercises (*παιδοτρίβαι*). We accordingly read in Plato of the palæstra of Taureas, which appears to have been one of the most celebrated. (Plato, *Charmid.*, c. i.; with Heindorf's *Note.*)

In most of the other cities of Greece the Palæstra formed a part of the Gymnasium. According to Müller (*Archäologie der Kunst*, p. 344) it included the *σταδίων, ἐφηβεῖον, σφαιριστήριον, ἀποδυτήριον, ἐλαιοθέσιον, ἀλειπτήριον, κονιστήριον, κολυμβήθρα, ξυστοί, περιδρομίδες*, in fact every part of the gymnasium except the outer porticos. It appears however more probable that the term palæstra was confined to the rooms which were appropriated to the exercises of the athletæ, who, it must be recollected, were persons who were especially trained for contending in the public games, and therefore needed a course of gymnastic exercises different from that which was usually pursued. That this view of the subject is correct, is shown by the statement of Pausanias, who informs us (vi. 21, s. 2), that in the gymnasium at Olympia there were palæstræ for the athletæ, and also by that of Plutarch, who says (*Symp.*, ii., *Probl.* 4) 'that the place in which all the athletæ exercise is called a palæstra.'

Among the Romans the terms Palæstra and Gymnasium are used as synonymous. Thus Vitruvius gives a description (v. 11) of a Greek gymnasium under the name of palæstra. In the Greek cities in Sicily and Italy there also appears to have been no distinction in use between the two words (Cic. *in Verr.*, ii. 14; Polyb., xv., p. 716, c.; Casaubon); whence the Romans probably came to use them in common. [GYMNASIUM.]

PALAME'DEA (Linn.), a genus of birds placed by Mr. Vigors among the Grallatores, with its congeners *Parra*, *Chauna*, *Rallus*, and *Fulica*, in the family *Rallidæ*. The same author thinks that with *Parra* may be allied *Palamedea*, Linn., and *Chauna*, Ill. (the *Parra chavaria* of the 'Systema Naturæ'), both of which seem to approach Parra in affinity, although the latter of them is so imperfectly known, that its situation cannot be decided with certainty. (*Linn. Trans.*, vol. xiv.)

Mr. Swainson (*Classification of Birds*) gives *Palamedea* a position between *Megapodius* and *Dicholophus* in his family *Megapodinæ* (*Megapodidæ ?*), which comes immediately after the subfamily *Columbinæ* of his family *Columbidæ*, and terminates his order *Rasores*.

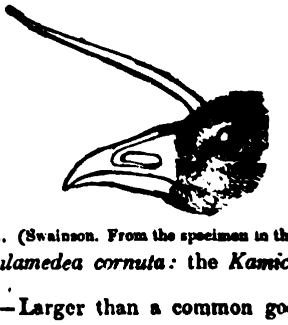
Cuvier places the form among his Macrodactylous Echassiers, or Waders (*Grallæ*, Linn.), between the *Jacanas* of Brisson (*Parra*, Linn.) [RALLIDÆ] and the Megapodes (*Megapodius*), under the title of *Kamichi* (*Palamedea*, Linn.), which contains *Palamedea* and *Chauna* of Illiger.

M. Lesson arranges the genus *Kamichi* (*Palamedea*, (Linn., *Anhima*, Briss.) under his family *Rallusinées*. *Palamedea* is immediately preceded by the Jacanas (*Parra*), and succeeded by the genus *Chavaria* (*Chauna*, Ill.), which last is followed by *Glareola*.

The *Palamedeidæ* then may be considered as a natural family consisting of the genera *Palamedea* and *Chauna*.

Palamedea.

Generic Character.—*Bill* shorter than the head, covered at the base with small feathers, conico-convex, slightly vaulted, hooked at the point. Forehead armed with a cylindrical *horn*, which is pointed.* *Nostrils* oval, open. *Wings* spurred, third and fourth quills longest. Anterior *toes* united at the base by a membrane; hallux touching the ground at the end.



Head of Palamedea. (Swainson. From the specimen in the British Museum.)

Example, *Palamedea cornuta:* the *Kamichi*, or *Horned Screamer*.

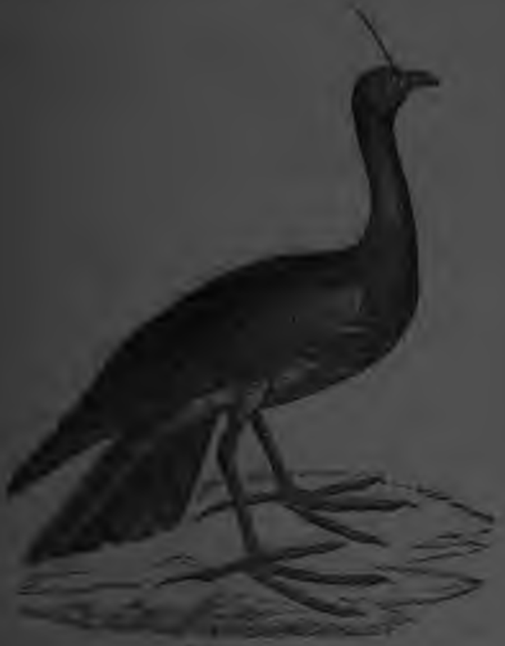
Description.—Larger than a common goose; greenish-brown above, except on the middle of the neck, which is variegated with black and white, and a large cinnamon-coloured spot on the shoulders; abdomen whitish; a long, spear-shaped horn projects from the forehead; wings long and pointed; tail wide and square; tarsi slender and reticulated, as well as the toes, which are long and almost entirely free; claw of the hallux nearly straight and very sharp; two spurs implanted on the edge of the wing.

---

* Mr. Swainson states that he believes that this long spear shaped horn is moveable at its root. There is a large lancet-shaped spur on the upper and anterior process of the upper part of the larger portion of the metacarpal bone, and another on the lower edge of that portion. These are firmly fixed on a bony core; and there is also a small spur on the end of the smaller metacarpal bone.

This, the only known species, is the *Anhima* of the Brazilians, and, according to Cuvier, the *Camouche* of the people of Guyana; but M. Lesson thinks that it is the *Kamichi* of Buffon.

Habits.—This extraordinary bird lives in the marshy or inundated places in South America (Guiana and Brazil), which it makes resound with its wild and loud cry. Its food consists of grains and aquatic herbs, as its muscular stomach would indicate, though there are not wanting those who state that it hunts reptiles. It pairs, and lives faithfully with its mate.



Palamedea cornuta.

Chauna.

Generic Character.—*Bill* shorter than the head, clothed with small plumes at the base, semiconvex, slightly vaulted, curved at the point; head unarmed; lore naked. *Wings* spurred. External *toes* united at the base by a membrane; hallux touching the ground at the end; posterior and intermediate claws nearly straight. *Tail* graduated.

Example, *Chauna Chavaria*.

Description.—No horn; occiput ornamented with a circle of feathers capable of elevation; head and upper part of the neck downy; a black collar; the rest of the plumage lead colour and blackish, with a white spot on the bend of the wing and another on the base of some of the greater quills; hardly any part of the leg naked. Length of adult, 32 inches.

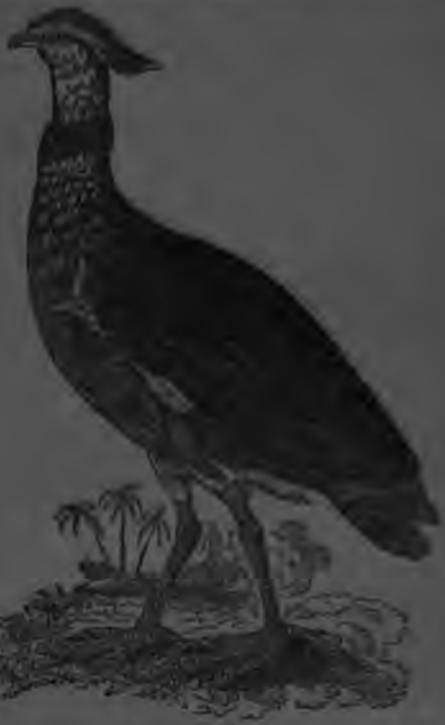
This is the *Chaña* or *Chajá* (a name, as we shall presently see, derived from the cry of the bird) of the people of *Paraguay*.

Habits.—D'Azara has given us many interesting particulars relating to this bird. Its sharp clarion-like cry is excited not only during the day, but also in the night, if it hears any noise. The note of the male is expressed by the word *Chajá*, and that of the female (for they answer each other) by the word *Chahali*. They are seen sometimes singly, sometimes in pairs, and at other times in numerous flocks. They principally, indeed ordinarily, frequent marshes, and if they are at any time found on the banks of rivers it is in places where the water is low and runs sluggishly. They do not swim, but enter the water like Herons, but not like them in search of fish or frogs, but for the submerged seeds of aquatic plants on which they live.

D'Azara saw some brought up among the domestic poultry at country-houses, and they were as tame as fowls. Those who kept them told him that the Chaña ate bits of raw meat, but he saw them picking the grass. They perch on the tops of the highest trees. On the ground they walk with gravity. Some state that the nests are spacious, and formed of small branches on bushes surrounded with water, and others that the bird places it in the rushes in the midst of the water. The eggs are laid in the beginning of August, and the young, which are two in number, follow their parents, though they are only clothed with down.

The Indians of Carthagena rear them among their geese and other poultry, under the idea that they will act as a guard, for the Chaña is very courageous and will drive away a vulture. D'Azara says that both this bird and the Kamichi are provided with a cottony down at the base of the feathers like swansdown; that the plumage of the neck is a little loose and inclining to downy; and that the skin of the neck is separated from the flesh by an interval of a line and a half, which is filled with cellular integuments, into which the air is introduced. The down at the base of the plumage is evidently calculated to keep up the proper temperature of the bird in its marshy home, and to repel the water when it wades so deep as to immerse the plumage.

Locality, Paraguay, on both banks of the Rio de la Plata, and in Brazil, far from human habitations.



Chauna Chavaria.

This genus *Chauna* was established by Illiger for the purpose of separating from the *Kamichi*, the *Parra Chavaria* of Linnæus, the *Chaña* of D'Azara. Cuvier, as we have seen, did not separate it from *Palamedea*, and M. Temminck, in his 'Analysis,' in mentioning the genus *Chavaria*, expresses his opinion that the *Chaña* ought not to form more than a species of *Kamichi*. The same author has subsequently, in his 'Planches coloriées,' placed it with that genus. Mr. Swainson arranges it as a species of *Palamedea* under the name of *Palamedea cristata*. The general opinion seems to be that the bird should be considered as a species of the genus *Palamedea*, and that the genus *Chauna* should be obliterated.

PALATE is the partition which separates the cavity of the mouth from that of the nose, forming the *roof* of the one and the floor of the other. In man it is composed of two portions, which are called respectively the hard and the soft palate: the *former* is made up of the inferior or palatine processes of each superior maxillary bone and palate bone, which, meeting in the middle line of the body, form a somewhat flattened arch over the mouth; the latter consists of a membranous curtain of muscular and cellular tissue, of which one margin is attached to the posterior border of the hard palate, and the other, with the uvula appended to its middle, hangs loosely backwards into the cavity of the pharynx. Both the hard and the soft palate are covered by a thin layer of vascular mucous membrane, immediately beneath which there are numerous minute glands. On each side, the soft palate is continued downwards in two diverging and arched membranous folds (the arches of the palate), which form the lateral boundaries of the fauces, and between which on each side the tonsil lies. Beneath these folds are muscles passing from the soft palate to the sides of the tongue and pharynx.

The hard palate serves as a firm support against which the food may be pressed by the back of the tongue during mastication; and it is by the various actions of the tongue upon it that we articulate several letters, as *d*, *g*, *j*, *k*, *q*, &c. The soft palate is capable of such motions by the contractions of its muscles, that it can either be raised so as to close the passage from the pharynx to the nose and Eustachian tube, or be depressed so as (with the assistance of the tongue) to close the passage from the pharynx to the mouth, or even to close both those apertures. By a simultaneous descent of the soft palate and contraction of the lateral arches by which it is connected with the tongue, the food when forced to the back part of the latter organ is impelled into the pharynx, constituting the first part of the act of swallowing. The soft palate is also of great importance in the actions by which substances are expelled from the digestive and respiratory organs through the mouth or nose, directing their passage, according to circumstances, into one or other of those cavities, as in coughing, sneezing, vomiting, &c.

The chief affection to which the palate is liable is that called cleft palate, a congenital malformation of the same nature as hare-lip [HARE-LIP], in which a fissure extends along more or less of the palate, and forms an unnatural communication between the mouth and the nose. Such a fissure may extend from the back of the teeth through the whole of both the hard and soft palates, or it may consist only in a small aperture in one or other of them. It may also vary in width, and may incline more or less to either side. According to its size, it produces inconvenience by allowing the passage of substances from the mouth to the nose, or in the opposite direction, and by impairing the speech by permitting the air impelled towards the front of the mouth to pass through the nose; hence the peculiar nasal and blowing sound by which the speech of persons thus affected is distinguished. Various operations have been proposed for the cure of this deformity. Those on the soft palate are conducted on the same principles as the operation for hare-lip, modified so as to meet the peculiar difficulties which arise from the position of the part. Those on the hard palate consist of either cauterising the edges of the fissure, or endeavouring to make a portion turned up from the adjacent membrane, to adhere to its edges. No operation however can be performed on the hard palate with any hope of success when the fissure is extensive; and the results of those on the soft palate are generally very uncertain. The patient must usually be contented with the palliation that is afforded by a false palate, which consists of a plate of gold or silver adapted to the roof of the mouth so as to cover the aperture in it, and fixed there either by springs and wires attached to the teeth, or by sponge passed through the aperture into the nostril.

PALATINATE, THE. There were formerly two states in Germany of this name, which, till 1620, were under one sovereign: they were not contiguous, and were called, by way of distinction, the Upper Palatinate and the Lower Palatinate, which was called likewise the County Palatine of the Rhine, or the Palatinate of the Rhine.

The Upper Palatinate was bounded by Bayreuth, Bohemia, Neuburg, Bavaria, and the territory of Nürnberg. In 1807 its area was 2730 square miles, and the population 283,733. The capital and seat of government was Amberg. It now belongs to Bavaria. It is a very hilly and in general barren country: its chief wealth consists in the forests and pastures, and in its mines and quarries: it does not produce sufficient corn for the consumption of the inhabitants.

The Lower Palatinate was situated on both sides of the Rhine, and was bounded by Katzenelnbogen, Würtemberg, Baden, Alsace, Lorraine, and Treves. The chief cities were Mannheim and Heidelberg. It comprehended the principalities of Simmern, Zweibrucken (Deuxponts), Veldenz, and Lautern, and the County Palatine properly so called. It belonged to the elector palatine; and notwithstanding the ravages which it has suffered at different times, it is one of the most fertile and flourishing countries in Germany. Its area is about 1600 square miles, and the population is now above 300,000.

It is hardly necessary to trace the history of a country which, after having undergone numerous changes, is now divided among different German sovereigns, and the very name of which has disappeared from the maps of Germany. A few lines will suffice. The Counts Palatine of the Rhine had obtained, so far back as the eleventh century, the hereditary sovereignty of the County Palatine and of its dependent principalities. The Upper and Lower Palatinate remained united under one sovereign till 1620, when the elector Frederick V., who had married the Princess Elizabeth, daughter of James I., king of England, having been induced to accept the crown of Bohemia, was defeated in a battle near Prague, on which he was declared under the ban of the empire, and deprived of his dominions and his electoral dignity, which were given by the emperor Ferdinand II. (his cousin) to Bavaria, which has ever since retained the Upper Palatinate. Charles Lewis, son of Frederick, recovered the Lower Palatinate by the treaty of Westphalia: he likewise obtained a new electoral dignity, the eighth, with the dignity of hereditary treasurer; but Bavaria retained the Upper Palatinate, the rank (the fifth place) which the Palatinate before held in the electoral college, and the dignity of hereditary archcupbearer. It was however stipulated that in case the male line of the house of Bavaria should become extinct, that country and the above-mentioned rights should revert to the Palatinate. In 1706 Maximilian Emanuel, elector of Bavaria, being placed under the ban of the empire, the elector palatine John William recovered the Upper Palatinate and the antient rights of his house; but the elector of Bavaria obtained all he had lost by the treaty of peace concluded in 1714 between the emperor Charles VI. and Louis XIV. The Bavarian male line becoming extinct on the death of the elector Maximilian III. in 1777, the elector palatine Charles Theodore succeeded to his estates (with the exception of a small portion which came to Austria), and transferred his residence to Munich. Conformably to the stipulations of the treaty of Westphalia, he recovered the fifth place in the electoral college and the dignity of hereditary archcupbearer, and gave up the dignity of hereditary treasurer to the elector of Brunswick. Charles Theodore dying without issue in 1799, he was succeeded by Maximilian Joseph, duke of Deuxponts. [BAVARIA.]

In the wars of the French Revolution, the French took possession of that part of the Palatinate which lay on the left bank of the Rhine, and retained it by the treaty of Luneville, 1801. Thus Deuxponts, Simmern, Veldenz, Spanheim, &c., and about 930 square miles of the Palatinate proper, were lost. The territory on the right bank of the Rhine, 650 square miles, with 141,000 inhabitants, and a revenue of 600,000 florins, were ceded by Bavaria in 1802, for other provinces. Baden obtained about 380 square miles, with the cities of Mannheim and Heidelberg, and 103,000 inhabitants; Hesse-Darmstadt, 116 square miles, with 9750 inhabitants; and the princes of Leiningen, 140 square miles, with 26,500 inabitants. By the treaty of 1819, Bavaria recovered the greater part of the territory on the left bank of the Rhine which it had lost in 1801. The remainder was allotted to Hesse-Darmstadt and Prussia.

PALATINE COUNTIES. Two of the English counties, Chester and Lancaster, are counties palatine, and the earls of Chester and the dukes of Lancaster bear the titles of counts palatine. The county of Pembroke, in Wales, was also formerly a county palatine; but its palatine jurisdiction was taken away by the statute 27 Henry VIII c. 26. The archbishop of York, previously to the reign of Elizabeth, claimed to be a count palatine within his possessions of Hexham and H[illegible]hamshire, in Northumberland, and is so termed in some antient statutes; but by the stat. 14 Eliz., c. 13, it was declared that this district had no palatine jurisdiction or privileges.

Counts palatine were of feudal origin; and a reference to their history will clearly explain the meaning of the title, and also many of the incidents of these territorial dignities in England. Selden says 'the name was received here doubtless out of the use of the empire of France, and in the like notions as it had in that use' (*Titles of Honour*, part [illegible]). In the court of the antient kings of France, before the time of Charlemagne, there was a high judicial officer, called the

Comes Palatii: a kind of master of the household, whose functions nearly resembled those of the Præfectus Prætorio in the elder empire. This officer had supreme judicial authority in all causes that came to the king's immediate audience. (Selden's *Titles of Honour*, part ii., chap. 5.) When the seat of empire was transferred to France, this title and office still continued, but the nominal dignity, as well as a degree of jurisdiction and power analogous to those of the ancient functionary, were also given to a different class of persons. When the sovereign chose to confer a peculiar mark of distinction upon the holder of a certain fief or province, he expressly granted to him the right to exercise the same rank, power, and jurisdiction within his fief or province as the comes palatii exercised in the palace. Hence he also obtained the name of comes palatii or palatinus, and, by virtue of this grant he enjoyed within his territory a supreme and peculiar jurisdiction, having royalties, or jura imperii, by which he was distinguished from the ordinary comes, who had only an inferior and dependent authority within his district or county. This was the origin of the distinction between the Pfalzgraf and the Graf in Germany, and between the count palatine and the ordinary count or earl in England. Selden says that he had not observed the word 'palatine' thus used in England until about the reign of Henry II.

In conformity with this view of their origin, the counts palatine in England had jura regalia within their counties, subject only to the king's general superiority as sovereign; or, as Bracton expresses it (lib. iii., cap. 8), 'regalem habent potestatem in omnibus, salvo dominio Domini Regis sicut principis.' They had each a Chancery and Court of Common Pleas; they appointed their judges and magistrates and law officers; they pardoned treasons, murders, and felonies; all writs and judicial proceedings issued and were carried on in their names; and the king's writs were of no force within the counties palatine. Many of these powers, such as the appointment of judges and magistrates and the privilege of pardoning, were abolished by the stat. 27 Henry VIII., cap. 24, which also provided that all writs and process in counties palatine should from that time bear the king's name. The statute however expressly stipulates that writs shall be always witnessed in the name of the count palatine.

The county of Chester is a county palatine by prescription, being commonly supposed to have been first given with regal jurisdiction by William I. to Hugh d'Avranches. (Selden's *Titles of Honour*, part ii.) It was annexed to the crown by letters patent, in the reign of Henry III., and since that time it has always given the title of earl of Chester to the king's eldest son, and is preserved in the crown as a county palatine when there is no prince of Wales.

The county of Lancaster appears to have been first made a county palatine by Edward III., who, in the twenty-fifth year of his reign, in his patent of creation of Henry, the first duke, granted him the dignity of a count palatine, and afterwards, in the fiftieth year of his reign, granted the same dignity by letters patent to his son John, duke of Lancaster. Henry IV. was duke of Lancaster, by inheritance from his father John of Gaunt, at the time of his usurpation upon Richard II., but he avoided the union of the duchy with the crown by procuring an act of parliament which declared that the duchy of Lancaster should remain with him and his heirs for ever, in the same manner as if he had never been king of England. Upon the attainder of his grandson Henry VI., soon after the accession of Edward IV., the duchy became forfeited to the crown, and an act of parliament passed to incorporate the county palatine with the duchy of Lancaster, and to vest the whole in Edward IV. and his heirs, kings of England, for ever. Another act of parliament passed in the reign of Henry VII., confirming the duchy to the king and his heirs for ever; and from that time to the present it has continually been united to the crown.

Durham, like Chester, is a county palatine by prescription; but it is probable that the palatine jurisdiction did not exist long, if at all, before the Norman Conquest. (Surtees's *History of Durham*, Introd., p. 15.) 'Some do please to think,' says Selden (*Titles of Honour*, part ii., c. 5), 'that the palatine jurisdiction began there in Bishop Walcher, whom King William I. made both episcopus and dux provinciæ, that he might frænare rebellionem gentis gladio, et reformare mores eloquio,' as William of Malmesbury says. Durham continued as a county palatine in the hands of a subject till the year 1836, the bishop having been prince palatine, and possessing jura regalia till that time. By the stat. 6 & 7 Will. IV., c. 19, the palatine jurisdiction was separated from the bishopric and transferred to his Majesty, and vested in him and his successors as a franchise separate from the crown, together with all forfeitures, mines, and jura regalia. The jurisdiction of the courts was expressly excepted from the operation of the act.

PALATINE MOUNT. [ROME.]

PALAWAN. [SULU ARCHIPELAGO.]

PALEMBANG. [SUMATRA.]

PALE'NCIA (PALLA'NTIA), a city in Spain, formerly belonging to the province of León, but now the capital of a province of its name. It is situated in a fertile territory, watered by the river Carrion, on the bank of which it stands. It contains several churches and convents built in the Gothic style, the most remarkable of which is the cathedral, consecrated to San Antolin, and supposed to be the foundation of Sancho the Elder. At the beginning of the thirteenth century Palencia had a university, established by the bishop Rodrigo, the author of a Latin history of the Arabs and several other chronicles; but in 1239 the university was removed to Salamanca. Palencia is the see of a bishop. Its population, in 1827, amounted to 10,413 souls. It contained also before that period eleven convents, now suppressed. The principal trade of the inhabitants consists of woollen cloths and blankets, of which a considerable exportation takes place every year for the neighbouring provinces of Castile. Palencia is 65 miles south-east of León, and 24 of Valladolid; in 41° 59′ N. lat. and 4° 34′ E. long.

(Miñano, *Diccionario Geográfico*, vol. vi.)

PALE'NCIA, ALONSO DE, a celebrated Spanish historian of the fifteenth century, was born, as appears from his work 'De Synonymis,' cited by Pellicer (*Bibliotheca de Traductores*, p. 7), in 1423. At the age of seventeen he became page to Alfonso de Carthagena, bishop of Burgos, and author of the 'Doctrinal de Caballeros,' printed at Burgos in 1487, in whose family he acquired an early taste for letters. He afterwards visited Italy, where he became acquainted with the learned George of Trebizond, whose lectures on philosophy and rhetoric he attended. On his return to his native country he was raised to the dignity of royal historiographer by Alfonso, younger brother of Henry IV. of Castile. After Alfonso's death he attached himself to the fortune of Isabella, and was employed in many delicate negotiations, particularly in arranging the marriage of that princess with Ferdinand of Arragon. [FERDINAND.] On the accession of Isabella to the throne of Castile he was confirmed in his office of national chronicler, and passed the remainder of his life in the composition of philological and historical works, and translations from the classics. The time of his death is uncertain; but he must have lived to a good old age, since it appears from his own statement (Mendez, *Typographia Española*, Mad., 1796, p. 190) that his version of Josephus was not completed till the year 1492. The most popular of Palencia's writings are his 'Chronicle of Henry IV.' and his Latin 'Decades,' containing the reign of Isabella down to the taking of Baza from the Moors in 1489, neither of which has been printed, although an edition of the former work is now in course of publication by the Spanish Academy of History. Palencia's style, far from the scholastic pedantry so common among the writers of his age, exhibits the business-like manner of a man of the world. His sentiments are expressed with boldness; but the scenes he describes, and in which he himself was an actor, are sometimes delineated with party feeling. He passes however for one of the best Spanish historians, and his works are very much commended by Zurita, Clemencin, and other critics. Besides the two above-mentioned historical works, Palencia wrote 'El Universal Vocabulario en Latin y Romance,' Sev., 1490; 'Los libros de Flavio Josepho,' ib. 1491; 'Las Vidas de Plutarco,' ib. 1491; 'El Espejo de la Cruz,' ib. 1485; and several other works still in manuscript. Two copies of his MS. chronicle of Henry IV. are in the library of the British Museum, Bib. Eg., Nos. 297 and 298.

(Prescott's *History of Ferdinand and Isabella*, vol. i., p. 133; Nicolas Antonio, *Bib. Hisp. Vetus*, vol. ii., p. 327; Clemencin, 'Elogio de la Reyna Católica,' in the sixth volume of the *Mem. de la Acad. de la Hist.*)

PALENQUE. [MEXICAN STATES.]

PALERMO, *Intendenza*, or *Province of*, extends along the western part of the northern coast of Sicily, and is bounded on the east by the province of Messina, on the west by that of Trapani, and on the south by the provinces of Girgenti and Calatanisetta. Its area is reckoned at 1790 square miles. (Neigebaur.) The province of Palermo is divided into the four districts of Palermo, Corleone, Termini, and Cefalù, and according to the last census contained 475,570 inhabitants. It is the most populous of the seven administrative divisions of the island, and the population is yearly increasing. The surface consists partly of naked hills and partly of fertile valleys, among which that called the Conca, or 'shell,' of Palermo, is one of the finest regions in the world. The general slope of the ground is to the north, from the mountain-range, the Mount Nebrodes of the antients, which crosses the island from east to west, to the sea-coast. Numerous short watercourses run in that direction; they are dry, or nearly so, in summer, but become impassable torrents in the rainy season. The principal are the river Termini, the Fiume Torto, and the Fiume Grande between Termini and Cefalù. The principal productions of the country are corn, oil, oranges and lemons, manna, sumach, liquorice, almonds, pistachio nuts, and silk. Of late years manufactories have been established at Palermo, and in its neighbourhood of cotton and silk stuffs, straw-hats, soap, paper, and cream of tartar. The principal towns are: 1, Palermo. 2, Termini, a town of 15,000 inhabitants, with a harbour, a castle, and an old cathedral, in a fine situation: Mount Calogero, one of the principal summits of the Nebrodes ridge, rises behind it. The inhabitants of Termini are employed in the tunny, anchovy, and sardine fishery, and in maritime trade. The ruins of the antient Himera are about 12 miles distant. The hot mineral waters of Termini are much frequented, and supply the adjoining baths. 3, Cefalù, a town of 8000 inhabitants, built on the sea-coast at the foot of a high cliff, with a handsome collegiate church. 4, Corleone, an inland town, with 13,000 inhabitants, chiefly employed in agriculture. 5, Monreale, 5 miles west of Palermo, with 13,000 inhabitants, and a splendid Benedictine abbey, founded in 1174, the church of which has become the cathedral of the archiepiscopal see. It is rich in marble and paintings, and contains the tombs of the Norman kings William I. and II. 6, Carini, the antient Hyccara, 9 miles west of Palermo, the birthplace of the famous courtezan Laïs, has 6000 inhabitants. 7, Piana dei Greci, 15 miles south of Palermo, an Epirote colony, with about 5000 inhabitants and a Greek church.

The small island of Ustica, situated about 30 miles from the coast north by west of Palermo, contains about 1200 inhabitants. It has a small fort, and produces good wine.

PALERMO (the antient Panormus), the capital of the island of Sicily and the second city of the united kingdom of the Two Sicilies, is situated on the northern coast of Sicily, which here forms a deep bay between Capo di Gallo to the north-west and Cape Zafferano to the east. Palermo is situated in 38° 7′ N. lat. and 13° 22′ E. long., in a fine and fertile plain between two mountain ridges and the sea. The town is an oblong parallelogram, surrounded by walls furnished with bastions. It is rather more than four miles in circumference, the suburbs not included. A fine street, called Il Cassaro, a corruption of the Arabic word Al-kasr, 'the palace,' runs through its length from the sea to the royal palace, which is at the opposite or inland extremity of the town, and is crossed at right angles towards its middle by another handsome street, called Strada Macqueda. The square before the royal palace is adorned with a bronze statue of Philip IV. of Spain. Another smaller square, in the centre of the town, between the palace of the senate and the university, is decorated with a curious fountain enriched with statues and figures of various animals, which spout the water into several basins. The houses of Palermo are built nearly in the same style as those of Naples, with flat roofs and terraces, and balconies with Venetian blinds. The most remarkable buildings are the following:—1, The royal palace is an old building fortified like a castle, with a fine hall, a spacious court, and a splendid chapel, built by King Roger in 1129, and enriched with mosaics and with a fusion of alabaster, porphyry, and other valuable stones. On the summit of the palace is the Observatory, which was for many years under the direction of Father Piazzi, who discovered from it the planet Ceres in 1801. 2, The cathedral, a magnificent Gothic structure, built about the end of the twelfth century, is adorned with marble columns and statues; it contains the mausolea of King Roger, the Norman founder of the monarchy, of the emperor Henry VI., of his wife Constance, and their son Frederic II., the remains of each being deposited in a handsome porphyry urn. The great altar is very rich and adorned with lapis lazuli and gold. 3, The church 'del Gesù' is remarkable for its architecture and for the richness of its marble decorations, its paintings, and sculptures. Palermo has many other churches, most of which are deserving of notice, such as that of La Martorana, built in the twelfth century, in the Gothic or Saracenic style, those of the Teatini, of Olivella, of Santa Zita, S. Ignazio, S. Filippo Neri, all rich with marble, paintings, mosaics, &c. The church of the Capuchins is remarkable for its vaults, in which the bodies of the deceased monks and other persons are seen dried up standing in niches in various attitudes, and with their garments on, some being two or three hundred years old. The same display is exhibited in the Capuchin convent at Malta. 4, The university, founded in 1447, is attended by about 600 students, has a library of 40,000 volumes, a museum of antiquities, with some fine statues and a fine collection of Græco-Sicilian medals. The academy of the fine arts, annexed to the university, has a gallery of valuable paintings, chiefly bequeathed by the late prince of Belmonte. 5, Besides the great hospital, Palermo has several other hospitals, a foundlings' asylum, two monti di pietà, a new house for the insane, which is much extolled for its enlightened and humane method of discipline, an Albergo dei Poveri, or workhouse, and other beneficent institutions. 6, The palaces of the nobility, among which those of Princes Butera, Ventimiglia, and Trabia are the most remarkable. 7, The promenade along the sea-side, called La Marina, which leads to the fine public gardens called La Flora, with a botanical garden. Palermo has two theatres, several barracks for soldiers, and a castle, called Castello à Mare, which commands the roads. The harbour of Palermo is at some distance outside of the town, and is formed by an artificial mole, which however does not protect it effectually from the winds and waves.

Palermo is an archbishop's see, and the residence of the king's lieutenant-general over all Sicily. It has a supreme court of justice for the whole island, a court of appeal for the province, and a commercial tribunal. The province of Palermo contains 125 convents of men, inhabited by 905 professed monks, about 600 lay brothers or servants, and about 300 novices. The nunneries are also numerous. The religion is exclusively the Roman Catholic, and there is no Jewish synagogue nor Protestant chapel. For public instruction, besides the university, there are at Palermo a college, directed by the Jesuits, a house of education for young ladies, called 'Educandato Carolino,' a nautical school, and a veterinary college. There are a few elementary schools in the town, but there is no general system of elementary education in Sicily, nor are there any schools for females, except in the convents. (Serristori, *Statistica d'Italia*, 1836.)

The neighbourhood of Palermo contains many delightful villas and mansions of the nobility. The village called Bagaria, on the sea-coast east of Palermo, is remarkable for several of these, and especially for that of the Prince Palagonia, described by Swinburne, Brydone, and other travellers. In the opposite direction, west of Palermo, is the royal mansion and park of Bocca di Falco, beyond which is the handsome Benedictine convent of S. Martino, one of the wealthiest in Sicily, situated on a hill above a solitary and picturesque valley. The church is adorned with paintings and marble, and the convent contains a good library, a museum of Sicilian antiquities, and a collection of medals. The Mount Pellegrino, Mount Ercta of the antients, a strong position of the Carthaginians during the first Punic war, a broad rocky abrupt mass which rises north-west of Palermo, is a striking feature of the landscape. It is now famed among the natives for a grotto or cave which is said to have been the voluntary retreat of Santa Rosalia, a princess of the royal Norman blood, who in the bloom of her youth and beauty left the court of King Roger I. in order to lead a contemplative and ascetic life. The cave is become a sanctuary, and every year on the 15th July there is a solemn procession to this place from Palermo, and the town is illuminated for several days. This is the most brilliant season for seeing Palermo to advantage, as people flock to it from every part of the island.

At the foot of Mount Pellegrino is a royal park and preserve, called La Favorita, well stocked with pheasants and other game. The country-house called La Ficuzza be given also to the king, and was a favourite residence of the late King Ferdinand I. The other country residences near Palermo are those of Princess Butera, Villa Franca, Belmonte, and Valguarnera. Nearer to the town, in the suburb of Olivuzza, is a Saracenic castle called Zisa, raised by one of the emirs or governors of Sicily for his daughter, with Arabic inscriptions and other ornaments. Another castle of a similar style of architecture, called Cuba, lies farther on the road to Monreale, and is used as a cavalry barracks.

Two fine roads, the only carriage roads yet completed in Sicily, lead from Palermo, one to Monreale, and the other to Termini. The population of Palermo and its suburbs is reckoned at 140,000 by Ortolani ('Dizionario geografico della Sicilia,' 1819).

Palermo, under the name of Panormus (All-Port), was originally a Greek colony, though some pretend that the Phœnicians had previously a settlement on this spot. It afterwards became subject to the Carthaginians, until the first Punic war, when the consuls Aulus Atilius and C. Cornelius besieged and took the town. It afterwards became a Roman colony.

The Saracen emirs who ruled Sicily for several centuries made Panormus the capital of the island, and the Norman kings after them fixed their residence there. The Aragonese kings of Sicily resided at Palermo. When Sicily became united to the kingdom of Naples, Palermo lost its court, but retained the rank of capital of the kingdom of Sicily. During the late wars with the French it twice became a place of refuge to the Bourbon dynasty after their expulsion from Naples. Although somewhat fallen from its metropolitan splendour, it is still one of the finest, gayest, and most populous Italian cities.

(Mongitore, *Descrizione di Palermo Antico*, 1824-5; Scina, *Topografia di Palermo e suoi Contorni*; Valguarnera, *Discorso sull' Origine e Antichità di Palermo*; Inveges, *Annali della Città di Palermo*, 3 vols., fol., 1645-51.)

PALESTINE (*PALÆSTI'NA*) is the name commonly applied to the whole land anciently inhabited by the Israelites, including the country of the Philistines (Ptolemy, v. 16). It is derived from פְּלֶשֶׁת, *the land of the Philistines*. It was originally called the land of Canaan (*Exod.*, vi. 4). The Israelites themselves called it the land of Israel (ארץ ישראל, 1 *Sam.*, xiii. 19; 2 *Kings*, vi. 23; אדמת ישראל, *Ezek.*, vii. 2), and, with reference to the theocracy, the Holy Land (אדמת הקדש, *Zechar.*, ii. 16; 2 *Macc.*, i. 7), or the land of Jehovah (ארץ יהוה, *Hosea*, ix. 3; *Jer.*, ii. 7), and also the Promised Land (γῆ τῆς ἐπαγγελίας, *Heb.*, xi. 9). The Romans generally called it Judæa.

The precise boundaries of this country are not very well defined. It was adjacent on the south-west to the desert which lies east of the delta of Egypt, on the south and south-east to Arabia, on the east and north to Syria. Its frontier towns were Dan on the north and Beersheba on the south. On the west it is bounded by the Mediterranean Sea. Its southern boundary on the coast was a stream which is called in Scripture the River of Egypt (probably the brook of El-Arish), from the mouth of which the southern boundary extended eastward through the Arabian desert to a point about 25 geographical miles south of the Dead Sea. The northern boundary was formed by the mountains of Lebanon; the eastern by the river Jordan and its lakes. The country lay therefore between 31° 10′ and 33° 30′ N. lat., and between 34° 45′ and 35° 30′ E. long. Its length from north to south is about 150 geographical miles; its breadth increases gradually from the northern boundary, where it is not more than 20 miles, to the southern, where it is not less than 80; the average breadth is about 50 miles. This description applies to the country originally intended in Scripture by the term 'the Land of Promise,' &c.; but the name of Palestine is used in common in a wider sense, embracing a considerable territory to the east of the Jordan, the addition of which increases the average breadth to about 65 miles. The southern limit of this eastern territory was the river Arnon, which falls into the Dead Sea near its northern end. The whole country contained about 11,000 square miles, or about 3300 square miles more than the area of Wales.

In describing the physical geography of Palestine, we follow for the most part the 'Physical History of Palestine,' which forms a part of the 'Pictorial History of Palestine,' by the editor of the 'Pictorial Bible,' a work in which nearly all the information we possess upon the subject is collected.

Mountains.—Palestine is a very mountainous country. A mountain-range commences in Syria south of the Orontes, and stretches to the south as far as the sources of the Jordan, where it divides into two branches, which continue their course nearly parallel to each other, and enclose between them the valley of the Jordan and its lakes. These two ranges diverge from each other at the head of the Gulf of Akaba; the one running along the eastern coast of that gulf and terminating on the shores of the Red Sea; the other along the western coast of that gulf and terminating in the mountains of Sinai.

The mountains of Lebanon, which are a part of this mountain system, form the northern boundary of Palestine. They consist of two parallel ranges enclosing a fertile valley of the average width of fifteen miles, which was the antient Cœle-Syria (Hollow Syria), and is now called *El Bekaa* (the valley). The western range inclines towards the sea, and terminates at the mouth of the Leontes, near Tyre; the eastern extends southward into Palestine and divides into two branches, as above described. The name of Lebanon is applied in Scripture indifferently to either or both of these ranges: by the Syrian Greeks the western was called Libanus (now *Jebel-el-Gharbi*, the western mountain, or *Jebel Libnan*); and the eastern Anti-Libanus (now *Jebel-es-Sharki*, the eastern mountain). Lebanon is by far the highest part of the Syrian mountains. The summit of the western range is quite barren; but the lower slopes, especially on the western side, are inhabited and cultivated. Among the trees which grow upon them are the remains of the celebrated cedars of Lebanon. Anti-Libanus is in general not so high as the western ridge; but at the point where it divides into the two branches which enclose the basin of the Jordan, it rises above all the other summits of Lebanon, forming the *Jebel-es-Sheikh*, the Hermon of Scripture, whose summit is covered with perpetual snow. The height of these mountains has never been measured. The eastern range is more barren, and has fewer inhabitants than the western. As this range passes into Palestine, it diminishes in height, and becomes less rugged and more fit for tillage; but at the Dead Sea it consists of desolate rocks. Almost all the mountains of Palestine may be regarded as belonging to the two principal ranges which include the basin of the Jordan. The most remarkable are the following:—Mount Tabor, the highest mountain in Lower Galilee, stands on the north-east of the plain of Esdraelon. It is entirely detached from the surrounding mountains, and is nearly of an hemispherical figure. On its summit is a plain of about half an hour in circuit, which is enclosed by an antient wall. This mountain is said by an old tradition to have been the scene of our Saviour's transfiguration. A range of fertile hills about five miles south-south-west of Tabor is generally considered to be the Mount Hermon mentioned in the Psalms (*Ps.* xlii. 6; lxxxix. 12): it is called the Little Hermon, to distinguish it from the great peak of the same name in Anti-Libanus. To the south and south-east of Tabor are the mountains of Gilboa of Scripture (*Jebel Gilbo*), a sterile range of hills, about 1000 feet above the level of the sea: they bound the valley of the Jordan on the west for some miles. The range of Carmel, the termination of which forms the only very prominent headland on the sea-coast of Palestine, lies almost due west of Mount Tabor. The promontory in which it terminates encloses the Bay of Acre on the south, whence the ridge runs inland to the south-east till it joins the principal range. It is only of moderate height, and is covered with forests and grass. To the south of the plain of Esdraelon lie the mountains of Samaria, which are beautifully wooded, chiefly with olive trees, and covered with towns and villages. Of these mountains perhaps the highest are those of Ebal and Gerizim, which are separated from each other by a valley 200 or 300 paces broad. From these mountains were delivered the curses and the blessings of the Law. The Samaritans had their temple on Mount Gerizim, which they esteemed the holiest of mountains. Judæa, or the southern part of Palestine, is full of hills, which are divided by valleys and torrents, and are for the most part of moderate height. They are composed of a friable rock, particles of which are washed down by the torrents, and form terraces on the slopes of the mountains. In antient times these terraces were planted with the olive, the fig-tree, and the vine. At pre-tent the rocks are for the most part barren and desolate. In the eastern part of Judæa, on the borders of the Jordan and the Dead Sea, is a wilderness of mountains, the most rugged and desolate in all Palestine. This mountainous country, which is the highest in Judæa, bears the name of Quarantania, from a tradition that this was the wilderness in which Christ fasted forty days and nights: the highest summit among these mountains is called the Mountain of Temptation, and is pointed out by tradition as that from which the devil showed our Saviour the kingdoms of the world. The most mountainous part of Judæa is the district round Jerusalem. [JERUSALEM.]

Of the mountains on the east of the Jordan little is known. Beginning in the north at the *Jebel-es-Sheikh*, already noticed, we find the mountains continuing southwards for about twenty-five miles under the name of *Jebel Heish*, and terminating at a point about ten miles to the east of the lake of Gennesareth. To the south of this mountain, for about twenty-four miles, is an open country, equally divided by the river Jarmouk, and containing the pasture-lands of Argob and Bashan. To the south of this district lies the land of Gilead, the mountains of which are the most considerable on this side the Jordan: they are for the most part well wooded, chiefly with the oak and wild pistachio. To the south of the river Jabbok (*Zerka*) the mountains are less elevated though broader. About six miles to the south of the river Jabbok is a ridge running east and west for about seven miles, the name of which (*Jelaad*) bears a trace of the antient name of the country. As the principal chain approaches the latitude of the Dead Sea, it diminishes in breadth; and somewhat below the head of that sea it widens out again, and forms the mountains of Seir. [IDUMÆA.] Among the mountains at the head of the Dead Sea, and to the north of the river Arnon, was Nebo (probably *Attarous*), from the summit of which Moses was permitted to see the promised land.

Geology and Mineralogy.—'Limestone is the prevailing constituent of all the mountains of Syria, as well as of Asia Minor and Greece. The general character of the stone of the mountains which compose the great central ridges of Syria, or which ramify from them, is that of a hard calcareous rock, sonorous when struck, and of a whitish or pale yellow colour. It is in short a very hard kind of limestone, disposed in strata variously inclined, and, like all limestone strata, affording a great number of caverns, to which frequent allusion is made in the Scriptures. Some of them are capable of containing 1500 men, and there is one near Damascus which will even afford shelter to 4000.' (*Pict. Hist. of Palestine*, 'Phys. Hist.,' p. lviii.) In the extreme north of Palestine the calcareous rock is said by Burckhardt to be 'of considerable hardness, and of a reddish yellow colour.'

The limestone rocks of which Lebanon is composed are of a whitish colour, from which circumstance the name of the mountain is supposed to be derived. The strata (at least at one point noticed by Burckhardt) are horizontal, varying from a few yards up to thirty or forty yards in thickness. The rock which lines the valley of the Jordan and its lakes is of a texture much less compact than that of the mountains of Lebanon or of central Palestine; and it diminishes in compactness as we approach the Dead Sea. In the neighbourhood of *Om Keis*, to the south-east of the lake of Gennesareth, there is a considerable quantity of black basaltic rock among the calcareous stone which prevails on the east of the Jordan between the rivers Mandhur and Zerka. This black basaltic rock is also found in large quantities in the plain of the Haouran, farther to the east. In the mountains south of the Zerka the calcareous stone is interspersed with layers of sandstone of different colours, and large blocks of black basalt. The hills about Jerusalem are of a hard light-coloured limestone, which, as we approach the Dead Sea, is exchanged for white and greyish limestone of a looser texture, containing layers of a reddish micaceous stone (*saxum purum micaceum*). On the shores of the Dead Sea perpendicular strata of a reddish brittle earth are seen in several places. The black basaltic rock of the Haouran extends along the whole eastern border of the country. In the parts near the Jordan it is generally found in detached masses. Traces of basalt are also found on the west of the lake of Gennesareth. Slate is found about the Dead Sea.

In many places the hard calcareous stone is covered by rocks of a soft chalky substance containing corals, shells, and other marine exuviæ. In the chalky beds about the summit of Carmel are found hollow stones lined with sparry matter, which resemble petrified olives and other fruit. These 'lapides Judaici' (as they are called) are sold to pilgrims as an antidote against various diseases.

This chalky formation appears very conspicuously in the White Cape (*Ras el Abaid*) below Tyre, the Album Promontorium of the Romans.

There are indications of coal in various parts of Lebanon. At Cornale, east of Beirout, seams of coal are found of the thickness of three feet, which are worked under the direction of Mohammed Ali.

About the seaward bases of the Lebanon and Kesrawan mountains, and in other parts of Palestine, there are numerous fossil plants, fishes, and shells.

Palestine is abundantly supplied with salt from the Dead Sea and the Mediterranean. The water of the Dead Sea is intensely salt. Fragments and beds of salt are found about its shores. The salt is deposited in large quantities on the margin of the Dead Sea by the evaporation of its waters. Saltpetre is found in the district of the Haouran.

From the description which Moses gave of the promised land (*Deut.*, viii. 9), 'as a land whose stones are iron, and out of whose hills thou mayest dig brass (or copper),' we should expect to find indications of these metals; and that they were found in antient times appears from the frequent mention of them in the Jewish history. In modern times the mineral wealth of the country has been almost entirely neglected. Iron abounds in the Lebanon and Kesrawan mountains, and traces of it are found in other parts of the country. Of copper we have no information. Palestine possesses neither tin, lead, nor gold; but some traces of silver have been found. There are celebrated mines of asphaltum in the neighbourhood of Hasbeya, near the sources of the Jordan.

The indications of volcanic action are chiefly confined to the basin of the Jordan and its lakes; and they are most frequent about the lake of Tiberias and the Dead Sea. Hot springs, lava, and pumice-stone are found about the Dead Sea. There are hot-springs at Tiberias, on the western side of the lake of Tiberias, and at other places round the lake, which has itself a striking resemblance to the crater of a volcano. In the neighbourhood of the Dead Sea are still the mines of asphaltum (the 'slime pits') of which the vale of Siddim was full in antient times (*Gen.*, xiv. 10), and other traces of the 'brimstone, salt, and burning,' by which the cities of the plain were overthrown. Palestine has been the scene of repeated earthquakes. A very destructive one occurred in 1837.

Valleys, Plains, and Deserts.—From the general disposition of the high lands in Palestine, it follows that the chief valleys are longitudinal, and run from north to south. The transverse valleys have a general east and west direction, being formed by the offsets of the principal mountain ranges. The chief plain country is the low land along the Mediterranean on the west of the central range of mountains. The chief valleys are to the east of that range, and are the Bekka between Lebanon and Anti-Lebanon, the basin of the river Jordan and its lakes, and the great valley of Araba extending from the Dead Sea to the Ælanitic Gulf.

The flat country along the coast varies considerably in breadth, and is diversified by elevations which are offsets from the central mountains. The soil of this part of the country is very fertile, being composed of a rich brown mould. The climate along the coast is very warm. To the south of Cæsarea is the celebrated vale of Sharon, which is terminated in the neighbourhood of El Arish by a sandy desert (the wilderness of Shur and Paran) which extends westward to Egypt, and eastward to the peninsula of Sinai.

The country between the mountains of Libanus and Anti-Libanus formed the Cœle-Syria of the Greeks and Romans. Its length is about 90 miles, and its average breadth about 11: it is the richest and most beautiful part of Syria.

The great valley of the Jordan extends about 175 miles from the sources of the river in the north, to the southern extremity of the Dead Sea. It is bounded on both sides by mountains, which on the east rise almost precipitously from the bed of the river till near the head of the Dead Sea, where the valley becomes wider: on the west there is a fertile vale between the river and the mountains, averaging about a half or three-quarters of a mile in breadth, except at the lake of Gennesareth, where the mountains come close up to the shores. The valley of the Jordan is in fact a great longitudinal cleft, which traverses the country from north to south, and in its lowest part, the surface of the Dead Sea, is about 500 feet below the level of the Mediterranean. (*London Geog. Journal*, vol. viii., p. 250.) A recent traveller (*Russegger*) makes it 1400 feet below the level of the Mediterranean; but such a remarkable fact, which is opposed by other evidence, must be received with doubt. The valley is very warm, and as it also possesses abundance of water, it is singularly fertile. The name of the valley of the Jordan is usually restricted to the part between the lake of Tiberias and the Dead Sea (now called *El Ghor*), which is about 60 miles long, and 5 or 6 miles wide in the northern half, but it grows much wider towards the Dead Sea, near which it spreads out into the plain of Jericho on the west and the plains of Moab on the east of the Jordan. The plain of Jericho is about 15 miles long by 7 or 8 broad, and is bounded on the west by an amphitheatre of mountains, which, by concentrating the sun's rays, cause a great degree of heat in the plain, which is further increased by the sandy nature of the soil, and by the low level of the plain. The plain immediately surrounding the Dead Sea consists on the eastern side for the most part of a sandy desert, with a few cultivated spots; on the western side the soil is rich, the heat great, and water abundant; but on the immediate borders of the lake it is a dreary waste. The great valley of Araba, which extends from the south of the Dead Sea to the head of the Ælanitic Gulf, is not within the limits of Palestine properly so called.

The valleys of Galilee are generally small, but beautifully wooded. The valley of Abilene lies beyond the hills which skirt the coast between Cape Nakhoura and Acre. South-east of this is the valley of Zebulon, between 3 and 4 miles long by one broad, which contains some of the finest pasturage in the whole country. To the east of this, and about the same length, is the vale of Sepphoris. The vale of Nazareth is a kind of hollow enclosed by mountains on every side, and abounds with fig-trees and gardens. Behind the hills which bound the north-western part of the lake of Gennesareth is an extensive plain, forming a rich pasture-ground, which is much frequented by the Bedouins. It is called Dothan, from a village of that name.

On the borders of Galilee and Samaria lies the great plain of Esdraelon, called in Scripture the plain of Megiddo, and the valley of Jezreel. It is exceedingly fertile, and well adapted for growing corn. It has been the scene of some of the most remarkable battles recorded in the Jewish history, and of great battles in later times. Samaria is less mountainous than either Galilee or Judæa; it is beautifully wooded, and full of fertile plains. The valley of Jenin—through which lies the common route from Galilee to the city of Samaria—is about 10 miles long and 2 miles in its extreme width. About four miles south of Samaria is the vale of Shechem, between the mountains of Ebal and Gerizim, which is said to be watered by 365 springs. It opens east into a very fine plain which leads into the valley of Leban, after traversing which we enter into the kingdom of Judæa. This, at least in its present uncultivated state, is the least fertile part of all Palestine, being full of rugged mountains, and deficient in water and soil. The stony valley of Bethel lies about 9 miles to the north of Jerusalem. The valley of Jeremiah, to the north-west of Judæa, is long and narrow. It is connected by a narrow pass with the valley of Elah, which is pointed out by tradition as the scene of David's victory over Goliath. This is one of the pleasantest parts of Judæa. East of Jerusalem lies the valley of Jehoshaphat, about a mile in length and 200 yards in breadth. To the south of the city is the valley of the Son of Hinnom, or Gehenna, the ancient scene of the worship of Moloch: at the south-end of this valley is the spot which is supposed to be the Aceldama mentioned in the *Acts* (ch. i., ver. 19). To the south-west of Jerusalem on the road to Bethlehem lies the valley of Rephaim, which is upwards of 6 miles long. Near Hebron is the valley of Mamre, where was the sepulchre of Abraham. South of Jerusalem is the vale of Eshcol, about 10 miles long, celebrated for its grapes and [illegible]. Between the Dead Sea and the centre of Judæa are the deserts of St. Saba and Engeddi.

On the east side of the Jordan lie the rich pasture-lands of Argob and Bashan, extending from Mount Hermon to the river Jarmuk, a few miles south of the lake of Gennesareth. South of this was the land of Gilead, the limits of which are not precisely defined, but it may be considered as lying between the rivers Jarmuk and Jabbok. It is mountainous, and more so in the northern than in the southern part. Some portions of it are very fertile, and others are beautifully wooded. South of the Jabbok was the land of Moab, of which only a small part, that namely to the north of the Arnon, belonged to Palestine. This portion was occupied by the Amorites when the Israelites took possession of the country. [MOAB.]

The south of Palestine is skirted by the great sandy desert which extends to Egypt and Sinai. It bears various names, of which that of the Desert of Paran seems to be used in the widest extent. For a description of this desert the reader is referred to the *Pict. Hist. of Palestine*, 'Phys. Hist.,' p. cxlii.

Lakes and Rivers.—There are no considerable rivers on the sea-coast of Palestine, the greater number of the streams being only mountain torrents which flow down from the hills that run parallel to the coast. The Leontes (*Nahr Liettani*) is not, strictly speaking, a river of Palestine. It rises among the roots of the Lebanon mountains in the neighbourhood of Baalbec, and flows in a south-westerly course to the Mediterranean, into which it falls a little to the north of Tyre. The most important river of Palestine is the Jordan (*Sheriat-el-Kebir*), which rises nearly in the latitude of Tyre, and flows southwards through the valley between the two great mountain-ranges already noticed, and, after traversing the lakes of Samochonitis and Gennesareth, falls into the Dead Sea. Its source, or what is generally considered to be its source, is a cave on the north-east side of the village of Panias, or Banias. [BANIAS.] There are however three other springs which have been taken to be the true source of the Jordan, and perhaps this distinction might properly be assigned to a stream which rises in the hill of Tel-el-Kadi, about 3 miles north-west of Panias. After a course of about 15 miles, the river runs into the *Bahr-el-Houle*, the waters of Merom of the Old Testament, and the lake Samochonitis of Josephus. The size of this lake varies with the season of the year. Josephus makes it 7 miles long by half that breadth, which appears to be about the average size. The reeds which are used for writing grow on its margin. There are numerous water-fowl upon it, and it abounds in fish. The waters are muddy, and are said to be unwholesome.

After a course of 10 miles from the point where it quits this lake, the Jordan enters the *Bahr-el-Tabarieh*, the sea of Tiberias, or lake of Gennesareth, or sea of Galilee of the New Testament. The dimensions of this lake are stated by Buckingham to be from 12 to 15 miles long, and from 6 to 9 miles wide. It is surrounded by mountains, and all travellers describe its scenery as exceedingly beautiful. The water is cool and clear, and contains a great quantity of excellent fish. Its margin is the resort of innumerable birds. The course of the Jordan is distinctly traced in a smooth current right through the middle of the lake.

The Jordan flows from the southern angle of this lake through a narrow valley, which may be considered as the bed of the river, and the level of which is lower than that of the large valley around it, which we have before spoken of as the valley of the Jordan (*El Ghor*). This lower valley is about three-quarters of a mile in breadth, and is covered with trees and luxuriant herbage. In the winter it is inundated by the river. In the summer the Jordan is fordable in many places. Its course when it leaves the lake is very rapid, but it diminishes in speed as it proceeds. At its junction with the Dead Sea it is 200 or 300 feet broad. The whole course of this river is about 100 miles in a straight line, but not less than 130 miles if we take into account the windings of the stream.

The very remarkable lake which receives the waters of the Jordan occupies the site of the plain of Siddim, where stood Sodom and the other cities which God destroyed by fire in the time of Lot (*Gen.*, xiv. 3; xix. 24, 25). It is called in Scripture the Salt Sea, the Sea of the Plain, and the East Sea; the Romans called it the lake Asphaltites; and it now bears the name of the Dead Sea; it is called by the Arabs Bahr Lut. It is of an irregular oblong figure, lying nearly due north and south. The dimensions assigned to it by Josephus are 72 miles long by 18 broad; but this is generally considered too large an estimate. The waters and surrounding soil are so intensely impregnated with salt and sulphur, that no trees or plants grow on its banks, and no cattle can drink of its water. The consequence is that it is surrounded with that perfect desolation which has procured for it the name of the Dead Sea. It is said to contain no fish, but the accuracy of this statement is doubtful. Its surface is singularly still. The waters leave a saline crust on things of whatever kind they come in contact with, and the drift wood upon it becomes so intensely impregnated with salt that it will not burn. It sends forth sulphureous and bituminous exhalations, and at some seasons of the year its surface is covered with a dense mist. The water is perfectly clear, and nearly of the same colour as that of the sea, but much more salt and bitter, and of a much greater specific gravity. [Dead Sea.]

The following are the most important tributaries of the Jordan and its lakes. On the eastern side the Jarmouk (*Sheriat-el-Mandhur*), the Hieromax of the Romans, and the Jabbok (*Zerka*), both of which flow westward into the Jordan, the former entering it a little to the south of the lake of Gennesareth, the latter at a point about half-way between that lake and the Dead Sea; and the Arnon (*Modjeb*), which flows into the Dead Sea near its northern extremity, dividing Palestine from the land of Moab. On the western side, the brook Daphne, which flows into the lake Samochonitis; the brook which takes its name from the neighbouring town of Capernaum and flows into the lake of Gennesareth; the brook Aenon, which rises in the mountains of Ephraim and flows into the Jordan between the lake of Tiberias and the Dead Sea; and the brook Cedron, which flows from the Mount of Olives into the Dead Sea.

The chief rivers which fall into the Mediterranean are the Belus, which flows into the modern bay of Acre a little to the south of Ptolemais; the Kishon, which flows from Mount Tabor through the plain of Jezreel, and falls into the same bay at the foot of Mount Carmel; the Chorseus and Kanah, which fall into the sea on the north and south of Cæsarea respectively; the Jarkon, which falls into the sea at Joppa; and the Eshcol and Besor, which fall into the sea near Askelon and Gaza respectively. The extreme southern limit of the coast is formed by the river of Egypt, which is supposed to be the brook El-Arish.

Climate.—The climate of Palestine is temperate and the weather is not very variable. There are, properly speaking, only two seasons. The winter lasts from October to the beginning of April, and is distinguished principally by continual showers, which are called in Scripture the early and the latter rains. In summer, which lasts from June to September, there is a continuance of clear weather, with scarcely any rain; but very heavy dews fall in the night.

Population.—It is not easy to estimate the population of Palestine. A census taken in the time of David gave 1,300,000 men who could bear arms (2 *Sam.*, xxiv. 9), which would make the whole population amount to 5,000,000.

Political Divisions.—The political divisions of the country were very different at different periods of its history. The first notice we possess of the country is when Abraham came from Mesopotamia to dwell in it. It was then inhabited by the Canaanites, who were divided into the families of the Sidonians, Hittites, Jebusites, Amorites, Girgasites, Hivites, Arkites, Sinites, Arvadites, Zemarites, and Hamathites. Of these, the Sidonians inhabited the strip of coast about Sidon, between Lebanon and the Mediterranean, being a part of the district known in history under the name of Phœnicia [Phœnicia]; the Hittites dwelt about Hebron; the Jebusites about Jebus or Jerusalem; the Amorites in the mountains west of the Jordan; the Girgasites about the upper part of the river round Gergesa; the Hivites in the country to the north of Shechem; the Arkites around Arca, and the Sinites near them; the Arvadites in the little island Aradus; the Zemarites and Hamathites about Simyra and Hamath. The Philistines inhabited the sea-coast in the south-west of the country. [Philistines.] At this period God promised Abraham that he would give the land to his descendants. [Jews.] This promise was fulfilled in the conquest of the land of Canaan by the Israelites after their departure from Egypt. Upon that event Joshua divided the land by lot among the twelve tribes. Reuben, Gad, and half the tribe of Manasseh had their possessions on the east of the Jordan; the other tribes were located on its western side. Reuben was bounded on the south by the river Arnon, and on the north by the tribe of Gad, which inhabited part of the land of Gilead about the river Jabbok. On the north of Gad the half tribe of Manasseh extended to Mount Hermon and the sources of the Jordan. The whole of the southern part of the country, between the Dead Sea and the Mediterranean, was at first allotted to Judah; but this district being disproportionately large, the western part of it was given to Simeon and Dan. The small territory of Benjamin was bounded by Dan on the west, by Judah on the south, and by the Jordan on the east, and contained within its limits the city of Jerusalem. Ephraim possessed the country about Shechem, between the Mediterranean and the Jordan. To the north of Ephraim lay the second half of the tribe of Manasseh, also extending from the Mediterranean to the Jordan and on the coast as far north as Mount Carmel. Issachar had the valley of Jezreel, to the north and east of Manasseh. Zebulon lay next to the north, bounded by Asher on the west and by the lake of Gennesareth on the east. The land of Naphthali lay about the sources of the Jordan, north of Zebulon and east of Asher, which last tribe possessed the sea-coast about Tyre and a part of the valley of Lebanon.

These tribes, whose political relations have been treated of in the article Moses [vol. xv., p. 440], were united into one kingdom under Saul and David. By the conquests of David the territory of the Hebrews was extended to the north-east as far as the Euphrates, and to the south as far as the head of the Ælanitic Gulf. But his conquests, of which the greater part was speedily lost by his grandson Rehoboam, are never included under the name of Palestine. By the revolt of Jeroboam, Palestine was divided into the two kingdoms of Judah and Israel, of which the former included the territories of the tribes of Judah, Benjamin, Dan, and Simeon, having for its northern boundary a line drawn from a point on the Jordan a little north of the Dead Sea, westward to the Mediterranean at Joppa: the latter included all the rest of Palestine to the north of this line.

The kingdom of Israel was overthrown, and the people carried captive by the Assyrians. The country, being thus depopulated, was next inhabited by the neighbouring heathen people and by colonies from other parts of the Assyrian empire, who, mixing with the scattered remains of the tribes of Ephraim and Manasseh which were left about Samaria, formed the people spoken of in the New Testament as the Samaritans, who were regarded by the Jews as an impure race, and between whom and the Jews there always existed a strong mutual hatred.

In the year 588 B.C., Nebuchadnezzar overthrew the kingdom of Judah and carried the greater number of its inhabitants into captivity. Many were however left in the land as subjects of the Babylonish empire. Upon the conquest of Babylon by Cyrus, Palestine fell under the dominion of the Persians, under whom it was divided, for the purposes of government, into small circles (פֶּלֶךְ), each of which had its governor (שַׂר). By an edict of Cyrus, the Jews were permitted to return to Judæa and to rebuild Jerusalem and the Temple, but they still remained subject to Persia. When Alexander the Great invaded Asia, Palestine submitted to him without a struggle. After his death, the possession of it was the subject of fierce contests between the Greek kings of Egypt and of Syria. [Jews.] Having been driven to revolt by the oppressions of the Syrian kings, the Jews, under the leading of the Maccabees, recovered their independence and restored the kingdom of Judah. [Maccabees; Asmoneans.]

In the year 63 B.C. the country was conquered by Pompey, and it remained thenceforward in subjection to the Romans, by whom the part of it west of the Jordan was divided into the three provinces of Judæa, Samaria, and Galilæa. Judæa nearly coincided with the antient kingdom of Judah; its northern boundary was at the parallel of Joppa. Samaria extended to the north as far as the plain of Esdraelon. Galilee lay north of Samaria, reaching up to Lebanon, and having Phœnicia along its western coast; it was divided into Upper and Lower Galilee, the former containing the northern and the latter the southern half of the province. The former was also called Galilee of the Gentiles, as it was inhabited by Syrians, Greeks, Phœnicians, and Egyptians, as well as Jews. On the east of the Jordan lay the province of Peræa, between the Arnon and the Hieromax, and to the north of this the districts of Batanæa, Trachonitis, Auranitis, and Gaulanitis, which commonly had one governor with Palestine. The whole country was considered by the Romans as a part of Syria, though it sometimes had a separate governor.

Under Constantine, Palestine was divided into Prima, Secunda, and Tertia. Palæstina Prima included the country of the Philistines, Samaria, and the northern part of Judæa; its capital was Cæsarea. Palæstina Secunda included Galilee and part of the country east of the Jordan; its capital was Scythopolis. Palæstina Tertia (also called Salutaris) contained the southern part of Judæa and the whole of Idumæa; its capital was Petra.

Towns and Villages.—In Upper Galilee, near the sources of the Jordan, was Dan, more anciently called Laish, the most northern town of Palestine. In its immediate neighbourhood stood, in the time of the Romans, Cæsarea Philippi, or Paneas. At the point where the Jordan enters the lake of Gennesareth stood Bethsaida. This city was beautified by Philip the Tetrarch, who called it Julias. On the western side of the same lake were Capernaum, Chorazin, and Magdala. On the same side of the lake, but in Lower Galilee, was Tiberias (*Tabarieh*), to the west of which lay Cana (Kanna), and farther to the west Sepphoris (*Saffureh*), the principal city of the district; it was enlarged by Herod, who called it Dio-Cæsarea; south-east of Sepphoris was Nazareth (*Nassrah*). Near the source of the Kishon was Nain. The city of Esdraelon, the ancient Jezreel, stood in the great plain of the same name. West of it was Shunem. In the south-east corner of Galilee was Bethshan, or Bethsan (*Bisan*), afterwards Scythopolis.

The most ancient city of Samaria was the Shechem, or Sichem, of the Old Testament, the Sychar of the New, which stood in the valley between Mounts Ebal and Gerizim. The Romans erected close to it the city of Neapolis, which still retains the name of *Nablous*. Near to Shechem on the south-east was Jacob's well. A few miles to the north of Shechem lay Samaria, which was built by Omri, who transferred the capital of the kingdom of Israel from Tirzah to this city. It was rebuilt and beautified by Herod, who called it Sebaste, in honour of Augustus, which name it still bears. In the time of the Romans the chief city of Samaria was Cæsarea Palestinæ (*Kaisarieh*), on the sea-coast, which was built by Herod on the site of an insignificant place called Turris Stratonis. On the coast, north of Cæsarea, was Dora (*Tortura*), and near it En-dor; south of Cæsarea was Apollonia (*Abu Khaled*), a Greek town. To the south-east of this was Antipatris, formerly called Capharsaba; and south of this was Saron, whence the vale of Sharon obtained its name.

The chief city of Judæa was JERUSALEM, in the neighbourhood of which were the villages of Bethphage and Bethany, on the Mount of Olives, and Emmaus (afterwards called Nicopolis), farther to the north-west. Near Emmaus were Aijalon and Gibeon; and farther to the north Ephraim and Luz or Bethel. To the east of Bethel, and in the north-eastern corner of Judæa, lay Jericho, which is sometimes called in Scripture the City of Palm-trees. Between it and the Jordan was Gilgal; south of Jericho was [illegible]. Bethlehem or Ephratah (*Bait-el-lahm*) was about five miles to the south of Jerusalem. To the south of Jerusalem lay Hebron (*El Khalil*). Joppa (*Jaffa*) was the frontier town of Judæa and Samaria on the sea-coast; to the east of it lay Lydda or Diospolis (*Lud*). South-east of Joppa was Arimathea (*Ramleh*), and near it Modin, the residence of Mattathias, the father of the Maccabees. On the east of the Jordan, in the district of Batanæa, &c., were [illegible] (*[illegible]*), Hippos on the lake of Gennesareth, Golan or Gilan, one of the cities of refuge, and Gamala, on the same lake. In the north of Peræa, near the lake of Gennesareth, was Gadara (*Um Keis*), and to the south-west of it Pella, built by the Macedonians, and farther south Gerasa, now *Jerash*, and Jabesh-Gilead. Jerash contains a large mass of noble ruins of the Roman period, consisting of fortifications, two baths, and a naumachia, which is now converted into a corn field. On the Jabbok stood Ramoth-Gilead, one of the cities of refuge, and on a branch of the same river Amathus (*Amata*). In the southern part of Peræa was Heshbon (*Esbus*), the chief city of the Amorites; farther to the west was Betharan, which was beautified by Herod Antipas, who called it Livias; near it was the citadel of Machærus, where John the Baptist is said to have been beheaded.

The modern history of Palestine is more conveniently included under SYRIA. The only portions of it which demand a separate notice have been treated of under CRUSADES. At present the country forms a part of Syria, being included under the pashaliks of Damascus, Akka, and Tripoli, and forming part of the viceroyalty of the pasha of Egypt.

PALESTRI'NA, the ancient *Præneste*, a town in the Campagna, 20 miles east of Rome, built on the south-west slope of a high hill, which is an offset of the Apennine ridge that limits the valley of the Tiber on the east, and divides it from the high land of Abruzzo. This ridge is intersected at Tivoli by the river Anio, which forces its way through it, and falls in a cascade. From Tivoli the ridge runs in a south-east direction to Palestrina, where it forms a promontory terminating abruptly towards the south, but connected, by some undulating and wooded elevations, with the more southern group of the Alban Mount. These elevations, on which stands the small town of Zagarolo, which gives a ducal title to the Roman family of Rospigliosi, form the watershed between the streams that flow westward to the Tiber, and the waters of the Sacco, which runs south-east to the Liris. The hill of Palestrina commands a view of both valleys, as well as of the Pomptine marshes to the south in the direction of Astura. In the mountains north of Palestrina is the town of Poli, the ancient Bola, and in the opposite or southern direction, in the valley of the Sacco, is Valmontone, the ancient Vitellia. Palestrina is naturally a strong position, and has been fortified from the oldest times. The ancient Præneste extended above the site of the present town, its citadel crowning the summit of the hill, and by its lofty position it deserved the epithet of 'frigidum,' or 'cool,' given it by Horace. There are some remains of the ancient walls built of large irregular blocks of stone. A church, dedicated to St. Peter, has been raised on the site of the citadel. The modern town of Palestrina is half way up the slope of the hill, on the site of the ancient temple of Fortune, and about 750 feet above the sea. Palestrina is a small town, with 3600 inhabitants, and some manufactures of coarse woollen cloth; it is also a bishop's see. The palace, belonging to the family of Barberini, contains the celebrated mosaic found among the ruins of the temple of Fortune, and transferred in 1640 by the Cardinal Francis Barberini to a hall of his mansion. It represents apparently an Egyptian festival on the occasion of the annual inundation of the Nile, with numerous figures of men and animals; among the latter are the hippopotamus, the ibis, and the giraffe. The names of the various animals are expressed by the side of each in Greek characters. It is the finest and most perfect ancient mosaic in existence. Some believe it to have been made in the time of the later Ptolemies; others ascribe it to the reign of Hadrian. The latter is the opinion of Barthélemy, in his 'Dissertation on the Mosaic of Palestrina.'

Præneste was a town of the Latins, and of older date than Rome. Tradition attributed its foundation to a certain Cæculus, who, according to Cato and Servius, was a leader of shepherds and robbers. In the war of the Latins against Rome after the expulsion of Tarquinius, Præneste is said to have forsaken the Latin Confederation and allied itself to Rome. (Livy, ii. 19.) More than a century later we find Præneste siding with the Volsci against the Romans, when the militia of Præneste advanced to the very gates of Rome, and occasioned a great alarm in the city. They were however defeated by T. Q. Cincinnatus the Dictator on the banks of the Allia, in the year of Rome 374, after which Præneste submitted to Rome by capitulation (Livy, vi. 28, 29); but it is not said upon what terms, and we find in the next year that Præneste and other Latin towns were again in arms against Rome. It is stated by Livy that Præneste had seven towns or villages under its sway, which were taken by Cincinnatus. Thirty years later, Præneste was included in the great Latin league against Rome, which was defeated by L. Furius Camillus; the territory of the Prænestini was confiscated (Livy, viii. 13-14), and their town became subject to Rome like the rest of Latium. [LATINI.] No colony however was sent to Præneste, and the inhabitants continued in the condition of a municipium without the Roman citizenship. In the civil wars of Marius and Sulla, and after the death of the former, young Marius, being defeated by Sulla, took refuge within the walls of Præneste, where, being besieged by L. Ofella, one of Sulla's lieutenants, he tried to escape by a subterraneous passage; but finding himself discovered by the enemy, he ordered a slave to run him through the body. The town then surrendered, when Sulla ordered an indiscriminate slaughter of all the inhabitants. Præneste does not appear to have been destroyed, but it remained long after in a desolate state; and Cicero, 'De Lege Agraria,' ii. 28, complains that the ager or territory of that town was in the possession of a few individuals. Octavianus Cæsar sent a colony of veterans to Præneste. The temple of Fortune was the great attraction of the place, and people repaired from all parts of Italy to consult the oracle, which gave its responses either by the voice of the goddess or in written answers made out of characters stamped on dice, which were drawn from an urn by a child, and arranged in the shape of sentences by the sortilegi, or soothsayers attached to the service of the temple. Cicero (*De Divinatione*, ii. 41) speaks at length of the 'Sortes Prænestinæ,' but shows his disbelief in them. The oracle continued however to be resorted to under the empire: it was consulted by Tiberius, who stood in great awe of it, and it was one of the latest oracles in Italy that continued to be applied to. The temple was built on a magnificent scale and richly adorned.

In the middle ages, Præneste, or Palestrina, became the chief stronghold of the powerful baronial family of Colonna, who often disputed with the popes the possession of the Campagna and of Rome itself. Boniface VIII. having excommunicated the whole family and their partisans, besieged and took Palestrina, and destroyed it; but after his death, the Colonna recovered and fortified it again. Eugenius IV., in 1437, retook it from them. At last Urban VIII. gave it to his relatives the Barberini.

Many statues and other remains of antiquity have been found at Palestrina: among others, the Antinous, called Braschi, from being excavated under the pontificate of Pius VI. (Braschi.) Præneste was a favourite residence of the wealthy Romans during the summer heats.

(Suaresi, *Prænestæ Antiquæ Libri Duo*, Rome, 1655, with plans of the antient town and the temple of Fortune; Cecconi, *Storia di Palestrina*, Ascoli, 1756, with several antient inscriptions; Petrini, *Memorie Prenestine*, Rome, 1795.)

PALEY, WILLIAM. The biographies of this eminent man are exceedingly scanty; indeed his life is marked with few events calculated to attract the attention of mankind. The early part of it was spent as a tutor in the university of Cambridge; the latter, in the calm pursuits of the philosopher and the unostentatious discharge of professional duties. Mr. Meadley, his personal friend, who published a Life of him soon after his death, is the authority for the following brief memoir.

Paley was born at Peterborough, in the year 1743. He was descended from an old and respectable family in Craven, in the West Riding of Yorkshire. During his infancy, his father removed to Giggleswick in Yorkshire, near the family property, having been appointed head master of King Edward's school in that place. He was educated under his paternal roof, and speedily distinguished himself by great abilities, a studious disposition, and a ripeness and discrimination of intellect. In his seventeenth year he was entered a sizar of Christ's College, Cambridge; on which occasion his father declared—a declaration which the event fully verified—that he would turn out a 'very great man,' for he had by far the clearest head he had ever met with in his life. He graduated in January, 1763, and was senior wrangler. Having taken orders, he was elected fellow of his college in 1766, and soon after became one of the tutors. In 1775 his friend Dr. Law, bishop of Carlisle, presented him to the rectory of Musgrove in Westmoreland. Shortly afterwards he married, left the university, and retired to his living. He passed through a succession of preferments, of trifling value, in the diocese of Carlisle; and in the year 1794, Dr. Porteus, bishop of London, made him a prebendary of St. Paul's, and Dr. Prettyman promoted him to the subdeanery of Lincoln cathedral. The year following, the bishop of Durham, Dr. Barrington, gave him the valuable rectory of Bishop-Wearmouth. His time was now spent between his subdeanery and his living, with occasional visits to Craven and Cumberland; and his life, unchequered by any events of importance, was occupied in the quiet performance of his duties, the society of his friends, and in completing that series of works which will perpetuate his name. The latter part of his existence was painfully subject to attacks of disease, which terminated in his death in 1805.

In matters of opinion, Paley was most liberal-minded and charitable; nor could he perceive either the utility of repressing free inquiry, or the justice of persecution for those diversities of sentiment which must ever characterise mankind. He was an able supporter of the principles of civil and religious liberty; and when Wilberforce and Clarkson commenced their labours for the abolition of the slave-trade, he strenuously exerted himself to suppress that disgraceful traffic.

As a writer, he is distinguished not so much for originality as for that power of intellect by which he grasps a subject in all its bearings and handles it in a manner entirely his own, for the consummate skill with which he disposes and follows out his argument, and for a style peculiarly suited to philosophical investigations—strong, exact, and clear, and abounding in words and phrases which, though sometimes homely, express and illustrate his meaning most for- and most distinctly.

The greatest and most important of his works, 'The Principles of Moral and Political Philosophy,' was published in the year 1785. The general outlines of it had been delivered as lectures to his pupils when he was a tutor in the university. Though in some respects faulty, the work is a most valuable addition to the literature of our country. His desire of introducing into the foundation of his system too much of the exactness of demonstrative science has occasionally led him to define things which in their nature are indeterminate—which cannot be brought within the limits of a precise and formal definition. His account of the *law of honour* and of *virtue* is of this character. Hence his applications are sometimes fettered and his conclusions defective. Both in his metaphysical and ethical views, Paley was a follower of Locke. Locke, in excluding innate ideas, overlooks innate capacities; and Paley denies the existence of a moral sense—of any faculty by which the mind is enabled to discriminate right and wrong.

This work is divided into two parts,—Moral Philosophy, and Political Philosophy. In the first part, after giving some account of the law of honour, the law of the land, and the Scriptures, as rules of action; rejecting the notion of a moral sense, or an innate capacity of moral judgment; and defining what he means by human happiness and virtue,—Paley proceeds to explain the principles and lay down the foundation of his system. This he does in book ii., 'On Moral Obligation.' A man is said to be obliged when he is urged by a violent motive resulting from the command of another. In moral matters, the motive is the expectation of future reward or punishment, and the command is from God. Hence private happiness is the motive, and the will of God the rule. But how is the will of God known? From two sources—the declarations of Scripture, and the light of nature; and the method of coming at the divine will concerning any action, by the light of nature, is to inquire into the tendency of the action to promote or diminish the general happiness. Here then Paley arrives at his principle, that 'whatever is expedient is right. It is the utility of any moral rule alone which constitutes the obligation of it.' Its utility is to be determined by a consideration of general consequences; it must be expedient upon the whole, in the long run, in all its effects collateral and remote, as well as in those which are immediate and direct. Having settled his principle, he proceeds to apply it to the determination of moral duties. He takes a three-fold division of duties: viz. those which a man owes to his neighbour, or relative duties; those which he owes to himself; and those which he owes to God. The first set are determinate or indeterminate: determinate, such as promises, contracts, oaths. The obligation to keep a promise, according to the principle of expediency, arises from the circumstance that 'confidence in promises is essential to the intercourse of human life;' and the sense in which a promise is to be interpreted is that which the promiser knowingly and willingly conveys to the mind of the person to whom it is made. Contracts are mutual promises, and therefore governed by the same principles; consequently, whatever is expected by one side, and known to be so expected by the other, is to be deemed a part or condition of the contract. Oaths are to be interpreted according to the *animus imponentis*, *i.e.* in the sense which the imposer intends by them. Indeterminate duties are charity, gratitude, and the like. They are called indeterminate because no precise and formal limits can be assigned to their exercise. Another class belonging to this first set of duties originate from the constitution of the sexes. The second set of duties are those which a man owes to himself. As there are few duties or crimes whose effects are confined to the individual, little is said about them. A man's duty to himself consists in the care of his faculties and the preservation of his person, and the guarding against those practices which tend to injure the one or the other. The third division of duties are those which are due to God. In one sense, every duty is a duty to God; but there are some of which God is the object as well as the author: these are worship and reverence.

The second part of this work is devoted to the elements of political knowledge. In determining the grounds of civil government and the reasons of obedience to it, Paley is guided by the same principle as that which constitutes the foundation of his moral system—*Utility*. The controversies on the origin of government have been many and bitter. Sir Robert Filmer and his followers, among whom the Oxford Tractators are the most prominent of the present day, hold the notion of a divine and inalienable right in kings:

powers, and the corresponding obligation of passive obedience in their subjects. They contend that God vested in Adam, the father of mankind, an absolute power over his posterity, and that this power descends without diminution to kings, the representatives of Adam. Locke, on the other hand, supposes a Social Compact, a compact between the citizen and the state, as the ground of the relation in which they stand to each other; a mutual agreement as to the terms of their connexion, and the conditions on which one undertakes to govern and the other to obey. Paley rejects both theories. He puts the divine right of kings on the same footing as the divine right of constables,—the law of the land. Against the Social Compact he urges that it is false in fact and pregnant with dangerous conclusions. The principle he assigns as the only reason of the subject's obligation to civil obedience, is the 'Will of God, as collected from expediency.' *Public utility* is the foundation of all government. Hence, whatever irregularity, or violations of equity or fraud and violence may have been perpetrated in the acquisition of supreme power, when the state is once peaceably settled, and the good of its subjects promoted, obedience to it becomes a duty. On the other hand, whatever may have been the original legitimacy of the ruling authority, if it become corrupt, negligent of the public welfare, and cease to satisfy the expectations of the governed, it is right to put it down and establish another in its place. After defining and giving some account of civil liberty, in which, as in every other part of his work, he adheres strictly to his principle—*utility*, which he follows out to its consequences,—he proceeds to speak of the different forms of government, especially the British constitution, their advantages and disadvantages, the nature of crimes and punishments, and the administration of justice.

With respect to religious establishments also, *expediency* governs all his views and conclusions. As no form of church government is laid down in the New Testament, a religious establishment is no part of Christianity; it is only the means of inculcating it. But the means must be judged of according to their efficiency; this is the only standard; consequently the authority of a church establishment is founded in its utility. For the same reason tests and subscriptions ought to be made as simple and easy as possible; and when no present necessity requires unusual strictness, confessions of faith ought to be converted into articles of peace. In establishing a religion, where unanimity cannot be maintained, the will of the majority should be consulted, because less evil and inconvenience must attend this than any other plan. On the same principle persecution is condemned and toleration justified; because the former never produced any real change of opinion, whilst the latter encourages inquiry and advances the progress of truth.

The book ends with the subjects of population and provision, agriculture and commerce, and military establishments. 'The final view,' observes Paley, 'of all national politics is to produce the greatest quantity of happiness.' In legislation, in government, in levying war, this is the ruling principle; and in relation to these questions, as in every other part of his work, he applies it with great skill and with a most masterly judgment.

In 1790 he published his 'Horæ Paulinæ,' certainly the most original of his works, and executed with singular ability. He here opens a new department of evidence in favour of Christianity. By a comparison of St. Paul's Epistles with the history of that apostle as delivered in the Acts, and by marking what he designates the *undesigned* coincidences of the one with the other, he establishes the genuineness of both, and thus furnishes a novel and ingenious and at the same time a very conclusive species of testimony in behalf of revealed religion.

His 'View of the Evidences of Christianity' appeared in 1794. In the composition of this work he availed himself largely of the labours of the learned Lardner and of Bishop Douglas, but the materials are wrought up with so much address and disposed with so much skill, and the argument laid before the reader in so clear and convincing a form, that it is one of the most valuable and important works of the kind. The argument, which is opened and illustrated with singular ability, is briefly this:—A revelation can be made only by means of miraculous interference. To work a miracle is the sole prerogative of the Supreme Being. If therefore miracles have been wrought in confirmation of a religion, they are the visible testimony of God to the divine authority of that religion. Consequently, if the miracles alleged in behalf of Christianity were actually performed, the Christian religion must be the true one. Whether the miracles were actually performed or not, depends upon the credibility of those who professed to be witnesses of them, that is, the Apostles and first disciples of Jesus Christ; and their credibility is demonstrated from this consideration,—'that they passed their lives in labours, dangers, and sufferings voluntarily undergone in attestation of the accounts which they delivered, and solely in consequence of their belief in those accounts; and that they also submitted, from the same motives, to new rules of conduct.' They could not have been deceived; they must have known whether Christ was an impostor or not; they must have known whether the miracles he did were real or pretended. Neither could they have been deceivers; they had no intelligible purpose to accomplish by deception; they had everything to lose by it. On the other hand, by being still—by letting the subject rest, they might have escaped the sufferings they endured. It is perfectly inconceivable, and entirely out of all the principles of human action, that men should set about propagating what they know to be a lie, and yet not only gain nothing by it, but expose themselves to the manifest consequences—enmity and hatred, danger and death.

His last great work, 'Natural Theology,' was published in 1802. Here, as in all the rest of his productions, the matter is arranged and the argument followed out with consummate judgment. His object is to establish the fact of benevolent design in the works of the visible creation. Hence the existence of a Supreme Designing Intelligence is inferred; and his personality, unity, and goodness demonstrated. It is not only one of the most convincing, but one of the most delightful books in the English language. 'One knows not,' says an ingenious writer, 'which to admire most, the judicious selection of instances, the happy disposition of the materials, the suitableness of the style, the skilful management of the general argument, the decisive confutation of the several atheistic schemes, or the impressive and weighty reflections with which it concludes.'

A very valuable and important edition of this work, with notes and scientific illustrations, was published a few years since by Lord Brougham and Sir C. Bell, the former furnishing a preliminary discourse of natural theology. The discourse is divided into two parts; the first contains an exposition of the nature and character of the evidence on which natural theology rests, with the intention of proving that it is as much a science of induction as either physical or mental philosophy; and the second is devoted to a consideration of the advantages and pleasures which the study is calculated to afford. Subjoined to the volume are some notes on various metaphysical points connected with the subject.

Besides these works, Paley was the author of various sermons and tracts.

Of his works published during his lifetime, an edition, by Lynam, appeared in 1825. A complete edition, in 4 vols., containing posthumous sermons, was published by his son, the Rev. Edmund Paley, in 1838.

PALIBOTHRA. [HINDUSTAN, vol. xii., p. 223.]

PALIGHAT. [HINDUSTAN, p. 204.]

PALIMPSEST MANUSCRIPTS (παλίμψηστα) are manuscripts from which the original writing has been erased or washed out, and which have been then written on again. This practice is as old as the time of Cicero, as appears from a letter of his to Trebatius (*Ad Fam.*, vii. 18), in which he praises his friend for having been so economical as to write on a palimpsest, but says that he should like to know what those writings could have been which were considered of less importance than a letter. (Compare Martial, xiv. 7.) The scarcity and expense of parchment, and the demand for the writings of the fathers and books of devotion in the middle ages, frequently induced the monks to erase or wash out the writings of the classical authors to make room for those of the fathers. In many cases however they were not able to obliterate entirely the antient writing; and a careful examination of some of these palimpsest MSS. has led to the discovery of some valuable works and fragments of the classical authors. Among the most important of these discoveries is the treatise of Cicero, 'De Republica,' which was found in the Vatican library at Rome by Angelo Mai in a MS. which had been re-written with the commentary of St. Augustin on the Psalms. The Institutions of Gaius were also recovered in a similar manner in the library of the chapter of Verona. The original MS. which contained the Institutions had been erased, as far as was practicable, and had been re-written with the works, chiefly the epistles, of St. Jerome. [GAIUS; PARCHMENT.]

PALINU'RUS (Zoology), the name given by Fabricius to a genus of crustaceans which forms the tribe of *Langoustiens* in the system of M. Milne Edwards, being the fourth of his family of *Cuirassed Macrurians*, and characterised by the existence of antennæ of the ordinary form and the absence of didactylous pincers.

The *Palinuri*, or *Sea-crawfish*, as they are popularly called, have the body nearly cylindrical. Their *carapace* is nearly straight from before backwards, very convex transversely, and presents about its anterior third part a deep transverse furrow, which is directed forward on each side and separates the stomachal from the cardial and branchial regions, the only ones which can be well distinguished. The anterior border of the carapace is armed with two stout horns, which advance above the eyes and the base of the antennæ. On each side, below the eyes and nearer to the base of the external antennæ, there is a more or less strong tooth. A great number of spines also nearly always arm the cephalothoracic buckler, over whose surface they are disposed. The ophthalmic ring is free and exposed; the eyes are large, short, and rounded. The antennular ring is very much developed, and advances between the external antennæ, below and in front of the ophthalmic ring; sometimes it is triangular, and much longer than it is wide, and sometimes it is nearly square. The *internal antennæ*, which spring from the lower part of its anterior border, are very long; their first joint is entirely cylindrical, and so are the two next joints; they terminate by two multi-articulate filaments of varying length. The *external antennæ* are very stout and very long; their basilary joint, in which the auditory apparatus is lodged, is very large, and is joined to its congener so as to form in front of the mouth a very large epistome; the three succeeding joints are stout, moveable, and thorny; they constitute the basilary portion of the antennæ, and are succeeded by a multi-articulate stem which is very stout and very long. The *external jaw-feet* are small and pediform; their internal border is only a little or not at all toothed, very obtuse, and furnished with bundles of hairs; their palp is very small or entirely wanting, but they give insertion to a large flabelliform joint. The second pair of jaw-feet are small and vary in the form of their palp; the first pair have a very large palp, which completes the efferent branchial canal forwards, and terminates sometimes by a styliform appendage, sometimes by an oval blade in the form of a spatula. The mandibles are very stout, their edge is trenchant, and their palpiform stem is very slender. The *sternal plastron* is of large size and composed of five segments joined together; it is very narrow between the first pair of feet, but is enlarged from before backwards, and presents on reaching the penultimate pair a very considerable width. All the *feet* are monodactyle; the first pair, which are in general shorter and a little stouter than the others, terminate by a short stout finger, which is not very moveable; sometimes there is at its base a spine, which is the vestige of a thumb, but these organs are never even subchelliform. The third pair of feet are, in general, longer. The *abdomen* is very stout and very long; its first ring has no appendages, but each of the four succeeding rings gives insertion to a pair of false feet, composed, in the male, of a small basilary joint and a large oval terminal lamina, whilst in the female there are two similar laminæ, or at least a single lamina and a stemlet which is biarticulate and furnished with hairs. The caudal fin, formed by the seventh abdominal ring and the appendages of that which precedes it, is very large, and each of the laminæ of which it is composed remains flexible and half-horny for its two posterior third parts, whilst above it is crustaceous like the rest of the tegumentary skeleton.

The *branchiæ* are composed of cylindrical filaments, which are short and close after the manner of a brush; there are eighteen on each side—two above the second jaw-foot, three above the external jaw-foot, three above the anterior foot, four above each of the succeeding feet, and one above the fifth foot. A large flabelliform appendage elevates itself between each of the bundles of branchiæ. (M. E.)

The genus is composed of species of considerable size, remarkable for the hardness of their crusts, and spread over all seas. Rocky coasts are their favourite haunts.

M. Milne Edwards divides the genus into the two following sections, and places the tribe which they constitute between the *Scyllarians* [SCYLLARIANS] and the *Thalassinians* [THALASSINIANS].

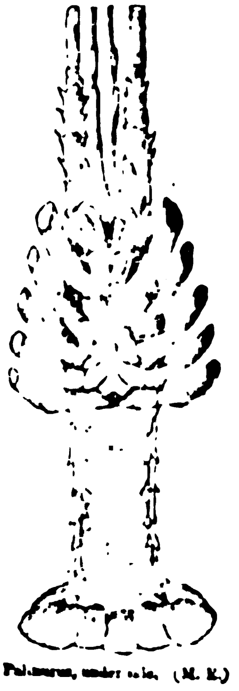
1.

Ordinary Palinuri.

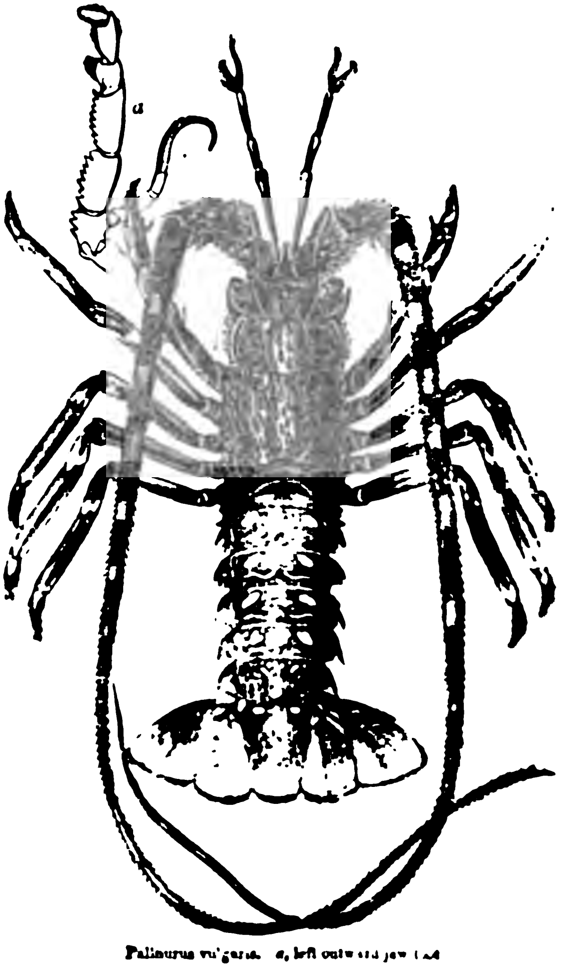
Distinguishable by the existence of a small, more or less projecting, median rostral tooth on the frontal edge of the carapace; a very narrow antennular ring, so that the external antennæ touch each other at the base, and cover the internal antennæ, which terminate by two very short multi-articulate stemlets.

Example, *Palinurus vulgaris*.

Description.—Lateral horns of the front smooth above



Palinurus, under side. (M. E.)



Palinurus vulgaris. a, left outward jaw foot.

and armed below with many sharp denticulations; carapace very spiny; subocular teeth on the border of the carapace very large. Abdomen almost entirely smooth, and presenting on the four rings which succeed the first, a transverse, deep, and hairy furrow, interrupted on the median line; the lateral prolongations formed by the angles of these rings, armed in their posterior border with three or four teeth situated near their base; two last rings of the abdomen spiny. Internal antennæ very slender and of moderate length. Anterior feet short and armed with a tooth at the extremity of the lower border of the penultimate joint. A vestige of an immoveable finger on the posterior feet of the female. First pair of abdominal false feet, in the female, furnished with two large oval laminæ, whilst those which succeed present only one lamina and a slender biarticulate appendage. Colour violaceous-brown spotted with yellow. Length about 18 inches. Weight sometimes from 12 to 15 lbs.

This appears to be the Κάραβος (*Carabus*) of Aristotle and the ancient Greeks, and the *Locusta* of the ancient Italian authors (*Rondeletius*, &c.) and of *Belon*. In the '*Portraits d'Oyseaux, &c.*' observez par P. Belon du Mans' (1557), is a cut of the crustacean, and under it the following lines, which allude to its name (*Locusta*), derived probably from its power of springing with the tail or abdomen:—

[illegible]

It is the *Common Sea-crayfish* of the shops, *Langouste* of the French.

Locality.—The seas of Europe. Common on the rocky coasts of Britain, especially in the south, and on the like coasts of France, especially on the south and west.

Utility to Man.—In general use as an article of food when in season, and as wholesome as the lobster; but though M. Milne Edwards states that the flesh is very much esteemed, the English specimens are certainly far inferior both in tenderness and delicacy of flavour to that of the last-mentioned crustacean.

The *Palinurus Rissonii* of M. Desmarest (green with white and reddish spots on the carapace and white lines on the abdomen), erroneously referred by M. Risso to *Palinurus fasciatus*, is in the last work of that naturalist (*Hist. Nat. de l'Europe Mérid.*) considered as a mere variety of *Palinurus vulgaris*.

Three other species of *Palinuri* are arranged by M. Milne Edwards under this section. Their localities are stated to be the Cape of Good Hope, Chili, and the Antilles.

γ.

Long-horned Palinuri.

No vestige of a median rostrum on the anterior border of the carapace; antennular ring very large and nearly square, so as to separate considerably the external antennæ, and to leave exposed the internal antennæ, which are terminated by two very long multi-articulate stemlets.

† Abdomen not furrowed.

Example, *Palinurus fasciatus*.

Description.—Antennular ring armed above with two conical rather large teeth situated near its anterior border. Carapace armed with a small number of spines, and slightly granular, or only dotted on its posterior half; lateral teeth of the anterior border of the carapace small; no spines on the median line of the stomachal region; median tooth of the anterior border of the epistome very large. Terminal appendage of the external jaw-feet oval. Abdomen smooth, finely dotted, and without transverse furrows; two or three small teeth towards the upper part of the posterior border of the lateral horns of the four abdominal rings which succeed the first. Feet slender. Colour greenish, with white [illegible] spots on the thorax, a white band near the posterior border of each abdominal ring, and many longitudinal whitish lines on the feet. Length about a foot.

Locality.—Indian Ocean.

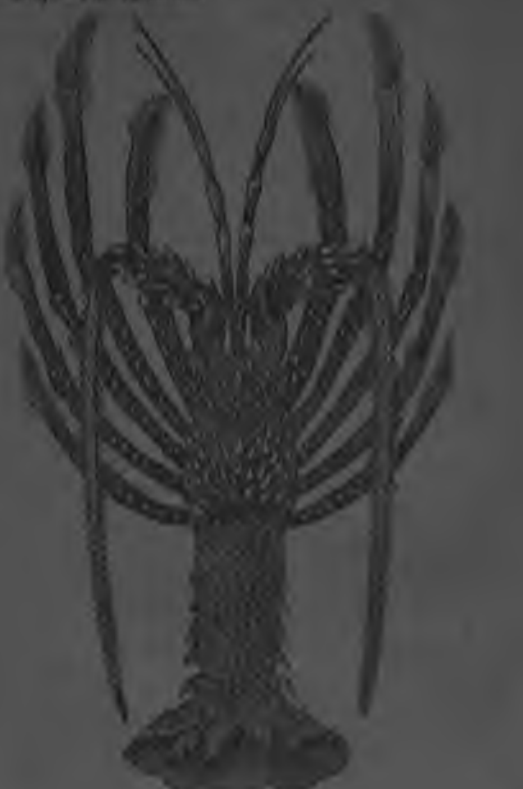
Two other species? one, *Palinurus ornatus*, from the Indian Seas and the Isle of France, and the other *P.* [illegible], from the coasts of India, come under this section. The latter may be, in the opinion of M. Milne Edwards, only a variety of the former.

†† Abdomen furrowed transversely.

Example, *Palinurus guttatus*.

Description.—Antennular ring armed with two very large conical teeth, sometimes preceded by two rudimentary spines. Carapace very spiny; two spines on the median line of the stomachal region near the base of the frontal horns; and on each side of these last, on the anterior border of the carapace, two teeth nearly as large as itself. Anterior border of the epistome armed with three nearly equal conical teeth, separated by a series of denticulations. Second pair of feet rather longer than the others. Abdomen smooth, and presenting towards the middle of each ring a transverse piliferous ring, which is not interrupted on the median line in the two first segments. A single tooth behind the base of the lateral horns of the abdomen. Colour green, with many circular yellowish spots; penultimate joint of the feet striated longitudinally with green and yellow. Length seven to eight inches.

Locality.—The Antilles.



Palinurus guttatus.

Five well-marked species from the seas of warm climates are also placed in this subsection by M. Milne Edwards, who observes that there is in the Paris Museum a foot of a *Palinurus*, which came from the Isle of France, appearing to belong to the third pair, and remarkable for its large proportions. This specimen leads to the presumption that there exists a gigantic species unknown to naturalists. The foot in question is more than two feet (French) in length.

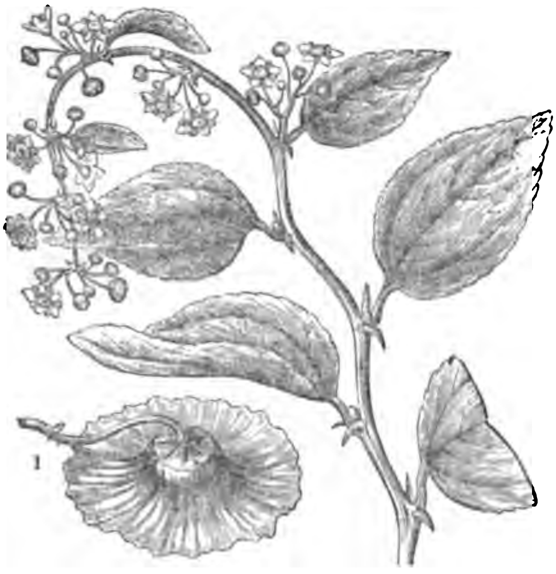
Fossil Palinuri.

M. Desmarest (*Crust. Foss.*) notices a large fossil crustacean from Monte Bolca, which evidently belongs to this genus, and is nearly of the same proportions as *Palinurus vulgaris*, but it is not sufficiently well preserved to identify the characters.

M. Milne Edwards further observes that M. Desmarest refers to this genus two other species of fossil crustaceans, but the former zoologist does not agree with the latter in opinion as to the relative affinities of these animals. *Palinurus Regleyanus* (Desm., *Crust. Foss.*) appears to M. Milne Edwards to have more analogy with the genus *Nephrops* than with any other macrurous crustacean; and *Palinurus Suerii* (Desm., *loc. cit.*), though evidently belonging to this *family*, does not, according to him, deserve to be considered as a true *Palinurus*, because the disposition of the regions of the carapace is very different. The upper part of the shell, instead of being divided into two portions only by a deep furrow situated in front of the branchial regions, is divided into three bands, the posterior of which is formed by the branchial regions, the anterior by the stomachal region, and the middle one by the highly developed hepatic or genital regions. There is also between this last portion of the carapace and the branchial regions a species of triangular shield, which represents the cardial region. The disposition of the rostrum is not observable, and it seems to M. Milne Edwards that when this fossil is better known it will form a distinct genus. It is from the muschelkalk.

M. Milne Edwards is also of opinion that the *Macraurites pseudoscyllarus* of Schlotheim, a fossil crustacean of singular structure, ought to be arranged under the family of *Cuirassed Macrurians*. The carapace is short, spiny, and terminated anteriorly by a small flattened rostrum; the antennæ are slender, and have an elongated peduncle. The first pair of feet are very stout, and spiny for two-thirds of their length, but appear to be terminated by a small nearly filiform didactylous hand. The succeeding feet are short, slender, and monodactyle. The abdomen is large, and nearly conformable with that of the *Palinuri*. One of the fossil Macrurians, he adds, figured in the *Oryctographia Norica* (pl. 8, f. 7), approaches nearly to the preceding. (*Hist. Nat. des Crust.*)

PALIU'RUS ACULEA'TUS, or AUSTRA'LIS, the Παλιούρι of the modern Greeks, is a small shrub, with flexuose shoots directed almost horizontally from the principal stem, and armed with short stiff curved spines, which grow in pairs from the base of the leaves. It has small shining ovate leaves, yellowish green clustered flowers, and a broad brown fruit, convex in the middle, but thin and uneven at the margin. It is common in the south-east of Europe and in Asia Minor, and is supposed to have been the plant from which the Jews platted the crown of thorns for our Saviour. In this country it is not uncommon in shrubberies, where it forms a beautiful bush when in flower, but it does not ripen its fruit. It is supposed to be the third sort of Ῥάμνος mentioned by Dioscorides, who compares the form of the fruit to that of a vertebra; if so the Παλιοῦρος of this author must have been something else, and perhaps, as Sibthorp conjectures, the modern Ζίζιφι, Ziziphus vulgaris, or Jujube.



Paliurus Aculeatus, or Christ's Thorn.

1, A ripe fruit, of the natural size.

PALL, a cloak or covering; more especially used for the ornamental article of dress granted by the pope to patriarchs and archbishops, made of white wool, in the form of a band three fingers broad, to surround the shoulders, having pendants a span in length before and behind, the ends ornamented with red crosses. The origin of the pall is obscure, but its use is of high antiquity. Tertullian, who lived at the beginning of the third century, wrote a treatise 'De Pallio.'

Sleidan, in his commentaries 'De Statu Religionis et Reipublicæ, Carolo V., Cæsare,' 4to., Argent., 1555, lib. xiii., p. 210, describes the ceremony of making the pall. He says, on St. Agnes day, Jan. 21, when, in the mass which is said in St. Agnes Church at Rome, they come to the words *Agnus Dei qui tollit peccata mundi*, two white lambs are laid upon the altar, which are afterwards given to the care of two subdeacons of St. Peter's Church, who put them out to grass, and in due time shear them; the wool obtained from these lambs, being mixed with other wool, is spun, and afterwards woven into these palls. Thus woven, they are carried to the bodies of St. Peter and St. Paul, and after certain prayers said, are left with them all night. They are then received again by the subdeacons and laid up till an archbishop who requires one of them comes either in person or by his proctor to demand it. The price at which they are purchased from the pope, he adds, is considerable: nor is it lawful for an archbishop to use his predecessor's pall. If by exchange, or in any other way, a patriarch or metropolitan is removed to another church, although he had purchased a pall before, he must still be at the charge of a new one. Before the receipt of his pall, an archbishop cannot perform the functions of his office, even if he has been translated; nor can the archiepiscopal cross be borne before him.

The original grant of the pall from Pope Julius II. to archbishop Warham is still preserved among the Cottonian manuscripts in the British Museum; the following is the form: 'Ad honorem dei omnipotentis, et beatæ Mariæ Virginis, et beatorum Apostolorum Petri et Pauli ac domini nostri Julii, pp. ij. et sanctæ Romanæ Ecclesiæ, necnon Cantuariensis Ecclesiæ tibi commissæ, tradimus tibi Pallium de corpore beati Petri sumptum, plenitudinis videlicet pontificalis Officii, ut utaris eo infra Ecclesiam tuam certis diebus qui exprimuntur in privilegiis ei ab apostolica Sede concessis. Aloisius.'

In the East the pall is called *omophorion* (ὠμοφόριον), and has been used at least since the time of Chrysostom, who was charged with accusing three deacons of taking his omophorion. (Photii *Bibliotheca*, edit. Par. 1611, p. 55.) It is worn by all the Eastern bishops, above the phenolion, or vestment, during the eucharist; and, as used by them, resembles the antient pall much more nearly than that worn by Western metropolitans, approaching nearer to the shape of a cope.

(Du Cange, *Glossar.*, v. 'Pallium.;' Picart's *Religious Ceremonies;* Palmer, *Origines Liturgicæ*, 8vo., Oxf., 1832, pp. 317, 318.)

PALLA'COPAS. [Tigris.]

PALLA'DIO, ANDRE'A, an Italian architect whose name has become almost proverbial through Europe, and whom many critics still consider as one of the great masters of his art, more especially in all that appertains to taste. He was born at Vicenza in the Venetian territory, a city which is distinguished by the numerous structures with which he adorned it. Of his family, his early youth, and his first studies, scarcely anything certain is now known. It appears however that he studied with great diligence the writings of Vitruvius and Alberti, and that he found an encouraging patron in his countryman Gian-Giorgio Trissino, whose name still holds a conspicuous place in the annals of Italian literature. By him Andrea was taken to Rome three several times, and he turned these opportunities to such excellent account that scarcely an antient edifice of any note escaped his examination, while of many of them he made drawings and studies, and carefully noticed their construction.

He appears to have returned from the last of these journeys in 1547, when he was in his twenty-ninth year, and to have settled at Vicenza. His first work, or rather one in which he had a share, was the Palazzo Publico at Udine, begun by Giov. Fontana, a Vicentine architect and sculptor, and by some supposed to have been Palladio's instructor; but the first work of any importance entirely designed by himself was the Basilica or Palazzo della Ragione at Vicenza, a large antient Gothic structure, the exterior of which he entirely remodelled. He surrounded it on three sides by open loggie or porticos, forming two orders, Doric and Corinthian, in half columns, each including a smaller order of insulated columns whose entablature forms the impost to the arches which occupy the upper part of the larger intercolumns. So great was the reputation he at once acquired by this edifice, that he was shortly after summoned to Rome by Paul III., who wished to consult him respecting the works then in progress at St. Peter's. He accordingly visited that city for the fourth time, but Paul died before he arrived.

On his return he seems to have been overwhelmed with commissions, almost every one in Vicenza and its neighbourhood, who could afford to build, employing him to design there a mansion or villa, of which class of subjects the majority of his works consist. Though he executed comparatively few structures of great magnitude and importance he had numerous opportunities for displaying his invention upon a moderate scale, and creating a style of domestic architecture till then almost unknown—which no doubt is one reason why he has so generally been taken as a model by architects of other countries.

Among the numerous private mansions erected or designed by him at Vicenza are the palazzi Tiene, Valmarana, Chiericati, Porti, Capitanio, Barbarano, &c., and the celebrated Villa Capra or Rotonda at a short distance from the city, besides a great many villas and country-seats along the Brenta. But some of the mansions at Vicenza have never been completed, and others too evidently attest either the poverty or the excessive negligence of their present possessors.

The reputation acquired by these and similar works led to Palladio's being invited to Venice, as Sansovino, the chief architect there, was growing infirm. He was at first employed with some alterations at the convent Della Carità, consisting of a Corinthian atrium, and a cloister beyond it. This atrium is merely an open court about 42 feet wide by 30 in depth, with a colonnade of four Corinthian columns on each side, and on each hand within these colonnades is the entrance to what were affectedly called *Tablini*, which were merely two tolerably spacious rooms, one intended for the sacristy, the other for a chapter-house. The atrium just mentioned communicates immediately, through a door facing the entrance, with the larger inner court or cloister, about 80 by 55 feet, whose elevations present three orders, viz. a Doric and Ionic with open arches between the columns (six on each of the longer, five on each of the shorter sides), forming open galleries quite around, while the Corinthian order above them has windows of rather small proportions. Two churches afterwards erected by him in the same city afforded him an opportunity of displaying his talents in buildings of that class. The first of these, San Giorgio Maggiore, was begun in 1556, though the façade was not erected till 1610. The plan consists of a nave with two aisles, but so short in proportion to the rest, there being only three arches on each side, that the whole approaches to the form of a Greek cross. Of decoration too there is very little besides columns and entablatures, and the small columns and pediments forming the altar tabernacles; even the vaulting and dome being quite plain, with merely arcs-doubleaux formed by the upper semicircular windows. The front has a large composite order of four three-quarter columns supporting a pediment, and placed on very lofty pedestals, with a small order in Corinthian pilasters on each side, surmounted by a half pediment, the horizontal cornice and rest of their entablature being continued as a fascia between the larger columns. Yet although there is no lack of decoration, the intercolumns, except the centre one (occupied by a lofty door, square-headed but with an arch over it), being filled by niches and pannels, and there being, besides, festoons between the composite capitals, the architecture itself is by no means rich; none of the mouldings are carved, and the modillions of the cornices are mere blocks. The same may be said of the still more celebrated church called Il Redentore, begun in 1578, about two years before the architect's death. In description the façade of this edifice agrees very nearly with that of the preceding, being similarly disposed, with a large composite order and a lesser Corinthian one, with half pediments. At the same time there are considerable differences, for instead of being raised upon pedestals, the larger order stands upon the platform of a flight of steps occupying the centre division of the front, and, instead of four three-quarter columns, consists of two half-columns and two pilasters. The proportions again are quite dissimilar, owing to the omission of pedestals, the greater width of the intercolumns, and the relative sizes of the two orders, the Corinthian one being here much larger than in the other instance, so that the cornice of its entablature is nearly level with the top of the shafts of the larger columns, whereas at S. Giorgio the smaller cornice is not higher than two-thirds of the larger columns. Neither is the lesser entablature here continued throughout, but its architrave alone, except in the centre intercolumn, where there are two Corinthian half-columns to the door, surmounted by an entablature and pediment, besides which there are smaller columns and segmental pediments to the niches in the lateral divisions of this centre compartment. All these different columns, pediments, and half-pediments tend to produce quite as much monotony as variety. In its plan this church greatly surpasses the other, having a good deal of play and elegance in its arrangement, and being more imposing in its proportions. Still here, again, the order itself constitutes the whole of the architecture; all the rest being bare and cold, and plain almost to nakedness.

The façade of San Francesco della Vigna was also designed by Palladio in 1562, although the church itself is said to be by Sansovino. This front is very much like that of S. Giorgio, except that instead of a large pannel there is a semicircular window (in three compartments, or of the kind called a Palladian window) over the doorway, also a circular sculptured ornament within the pediment, and an inscription on the frieze.

One of his last if not his very latest work was the Teatro Olimpico at Vicenza, which he did not live to complete; for he died August 6th, 1580, at the age of sixty-two, and that structure was not entirely finished till 1583. It has been extravagantly extolled by many, and severely condemned by others as a piece of puerile architectural pedantry. Speaking of Palladio's buildings at Vicenza, Woods says of it, 'it is too celebrated to be omitted, yet as far as my own taste is concerned it might have slept in oblivion. The *scene*, which is the part most admired, borders upon trumpery.'

It may indeed be asserted of Palladio's works generally that they have been greatly and indiscriminately overpraised by successive writers, who seem to have merely repeated one another. Among the many who have extolled Palladio's extraordinary merits, but without attempting to shew wherein they consist, are the names of Goethe, Quatremère de Quincy, Forsyth, Hope, and Beckford.

Judging Palladio dispassionately, it is impossible to deny that his works abound with defects and solecisms that would hardly be tolerated in any one else. We do not speak of engaged columns and matters of that sort belonging to the system itself, nor of the dryness and littleness of manner frequently resulting from an order being adapted only to a single floor of a building, one consequence of which practice is that notwithstanding so much stress is laid upon proportions, the due proportion that should be observed between the columns and the windows is almost lost sight of; but we speak of such positive errors as windows cutting into architraves, windows within friezes, doors lower than windows, figures on the raking cornices of window pediments, naked and dressed windows in the same composition, &c.; besides other faults which, if they do not run counter to rule, are yet sins against beauty and good taste, such as ugly balusters, mean attics, offensively wide intercolumns, heavy pediments, meagre entablatures and columns, particularly in the Ionic order, and above all a dryness, mannerism, and monotony of detail. As regards Palladio himself, there may be much excuse for his errors, but certainly none for the prejudices of those who would now insist upon our admiring his works without qualification, more particularly as nothing is easier than for a modern architect to avoid his faults, and even to improve upon his beauties.

PALLA'DIUM, a metal discovered by the late Dr. Wollaston in the grains of native platinum, in the year 1802; in these it exists to the amount of only about 1 per cent. He afterwards found it in the platinum sand of Brazil, in nearly pure grains of a divergingly fibrous texture, by which they are distinguishable from platinum. According to Breithaupt, the platiniferous sand of Siberia contains also grains of native palladium, which are flat and of a silver white colour. In the opinion of Levy, the primary form of these grains is a cube; their specific gravity varies from 11·8 to 12·14, and they contain very minute quantities of platinum and iridium. Their lustre is metallic, and their colour varies from silver white to steel grey; they scratch iron readily.

Palladium is usually obtained from the solution of the grains of platinum in aqua-regia, by the addition of cyanide of mercury after the greater part of the platinum has been separated by a salt of potash. [PLATINUM.] From the cyanide of palladium the metal is separated by a process which is tedious and rather complicated.

The properties of palladium are, that its colour is greyish white; it is very malleable and slightly elastic. Its density is 11·3 when fused, but 11·8 when rolled. It is almost as difficult of fusion as platinum. It is hard. It does not oxidize by exposure to the air.

Oxygen and Palladium have but little affinity for each other, and though palladium acquires a fine blue colour when exposed in the air to a strong heat, the oxidizement is so superficial, that no increase of weight can be ascertained. By the action of acids however, and especially of chlorine, it is converted into an oxide.

Protoxide of Palladium.—When carbonate of soda is added to a solution of the chloride or nitrate of palladium, brown hydrate of the protoxide is precipitated; and when this, after washing, is heated to redness, the water is expelled, and black oxide remains. When the nitrate is decomposed by heat, the same oxide is also procured; but if it be very strongly heated, it then loses oxygen; and it is not easily dissolved by acids after it has lost its water. It is composed of—

One equivalent of Oxygen .	8
One equivalent of Palladium .	54
Equivalent	62

Binoxide of Palladium is formed when a solution of potash is gradually poured on the double chloride of potassium and palladium in a dry state; by this is separated a compound of water, potash, and binoxide of palladium, which dissolves in an excess of the alkali; but the solution soon becomes gelatinous, and deposits a great part of the oxide combined with the potash. This, after washing with boiling water, abandons the greater portion of its water, and becomes black anhydrous binoxide of palladium; when strongly heated, it loses oxygen; it dissolves with difficulty in oxacids, and with dilute hydrochloric acid it yields chlorine. It is composed of—

Two equivalents of Oxygen .	16
One equivalent of Palladium .	54
Equivalent	70

Protochloride of Palladium is obtained by evaporating a solution of palladium in aqua-regia to dryness. It is a brown crystalline substance containing water, and becomes black when the water is dissipated. It is soluble in water, and when the dry salt is strongly heated, chlorine is expelled. It consists of—

One equivalent of Chlorine .	36
One equivalent of Palladium .	54
Equivalent	90

Bichloride of Palladium exists only in solution, and is procured by digesting the protochloride in aqua-regia; the solution has a very dark colour. With chloride of potassium it yields a double chloride of a red colour, whereas the protochloride yields a yellow double salt.

Carburet of Palladium is obtained by heating palladium foil in the flame of a spirit-lamp. This carburet is black and easily reducible.

Sulphuret of Palladium is of a greyish white colour and metallic lustre. It is fusible and is decomposable by heat. This compound is readily formed by heating its elements, with the evolution of light. When decomposed by heat, it yields a brownish powder, which appears to be a protosulphate of palladium, which is dissolved by hydrochloric acid, and when strongly heated is converted into metallic palladium. It consists of—

One equivalent of Sulphur .	16
One equivalent of Palladium .	54
Equivalent	70

Phosphuret of Palladium.—Phosphorus forms a fusible compound with palladium.

Alloys of Palladium.—This metal forms alloys, most of which are brittle, with arsenic, iron, bismuth, lead, tin, copper, silver, platinum, and gold; the alloy with nickel is ductile. A liquid amalgam is obtained by agitating it in a large quantity of mercury in a solution of palladium. But if the palladium precipitated by the mercury is in excess, a black metallic powder is obtained, formed of 48·7 parts of mercury and 51·3 of palladium: the mercury cannot be expelled from this compound, even at a white heat. Palladium, when fused with 6 parts of gold, destroys its colour; and this alloy was proposed by Dr. Wollaston for the graduated part of the mural circle of the Greenwich Observatory.

Salts of Palladium.—Nitrate of Palladium is obtained by treating it with nitric acid; the action takes place slowly unless assisted by heat, and the solution is of a red colour; by evaporation a red mass is procured, which is probably a subnitrate; the precipitate which it yields on the addition of cyanide of mercury is a fulminating compound.

Sulphate of Palladium is formed by dissolving the metal in sulphuric acid, or by decomposing the nitrate with it. It is a red soluble salt which is but little known.

Palladium has, of all metals, the greatest affinity for cyanogen, and the cyanide of mercury precipitates it from all its solutions, which gives an easy method of separating it from other metals; when the cyanide of palladium is heated, it is decomposed, and the palladium remains in its metallic state.

Most of the salts of palladium are soluble; those which contain the binoxide are little known; those of the protoxide are red or yellowish brown, and their solutions are of an intense yellowish red. Potash precipitates protohydrate of an orange colour, and sulphuretted hydrogen precipitates them of a deep brown. The protosulphate of iron and the metals which precipitate platinum throw down palladium in the metallic form. Ferrocyanide of potassium forms a yellow precipitate in the solutions of palladium, which is a cyanuret of iron and palladium; the cyanide of mercury precipitates a colourless cyanide of palladium. Protochloride of tin renders the solutions of palladium opaque, and gives a brown precipitate; but when they are sufficiently dilute, the colour becomes of a fine emerald green.

PALLA'DIUS, one of the Christian fathers, was bishop of Helenopolis in Bithynia, and author of a Greek work containing the lives of certain persons in Palestine and Egypt who made themselves remarkable at the time when he wrote by their religious austerities. This work was called the 'Lausiac History,' from Lausus, an officer in the imperial court at Constantinople, to whom it was dedicated. It is published in the *Bib. Pat. Morell.*, Par., 1644.

According to Cave, Palladius wrote his history about 421, in the fifty-third year of his age. We know nothing more of him, except that he was an Origenist and an admirer of Rufinus. He speaks very strongly against Jerome.

There was another writer of the same name, who composed a 'Dialogue of the Life of St. Chrysostom,' at Rome, in the year 408. It is not known whether he is the same or a different person from the former. Du Pin thinks him the same; Tillemont and Fabricius take him to be another person. His 'Dialogue' is published in the best editions of Chrysostom's works.

(Cave, *Hist. Lit.*, i., p. 376; Du Pin, *Bib. des Aut. Ecc.*; Lardner's *Works*, vol. iv., p. 410-11, and v., p. 6, ed. of 1831.)

PALLA'DIUS (Παλλάδιος), generally surnamed 'Sophista,' or 'Iatrosophista,' the author of three Greek medical works still extant. Nothing is known of the events of his life, but he is supposed to have gained his title of *ἰατροσοφιστής* by having been a professor of medicine at Alexandria. His age is also very uncertain: but as he quotes Galen (*De Febrib.*, pp. 6, 8, 12, 56, ed. Bernard), and he is himself several times mentioned by Rases, we may safely place him somewhere between the beginning of the third and the end of the ninth century A.D. Freind, in his 'Hist. of Physic,' argues that he must have lived after Aëtius, because the chapter 'De Epiala,' in his treatise 'De Febribus,' is taken word for word from that author; but this argument is by no means conclusive, because (as Bernard remarks in his preface) almost the very same words are to be found in Galen (*De Different. Febr.*, lib. ii., cap. 6), from whom therefore it is probable that both authors borrowed the passages in question. The first of his extant works is entitled *Περὶ πυρετῶν σύντομος σύνοψις*, 'De Febribus concisa Synopsis.' It consists of thirty chapters, and contains an account of the different kinds of fever (cap. 4, &c.), its causes (cap. 9), and its symptoms (cap. 10): it then treats separately of the different kinds of fever (cap. 14-18), and especially of the intermittent (cap. 19-23); and finally, in one short chapter, of the treatment (cap. 29). The treatise is too short to be of much value, and almost the whole of it is to be found in Galen, Aëtius, and Alexander Trallianus. It was first edited by Chartier, 4to., Gr. and Lat., Paris, 1646; the last and best edition is by J. St. Bernard, 8vo., Gr. and Lat., Lugd. Bat., 1745. It deserves to be noticed that though there are several MSS. of this treatise in different public libraries, not one of them bears the name of Palladius; but in some it is ascribed to Stephanus, in some to Theophilus, and in others to both. It is however, in the opinion of Freind (*Hist. of Physic*) and Bernard (*Præfat.*), clearly ascertained to be the work of Palladius, as he refers to it in another of his works entitled 'Εἰς ἕκτον τῶν Ἐπιδημιῶν Σχόλιον,' 'In Sextum (Hippocr.) Epidemiorum Librum Commentarius' (sect. 4, 9). This work is imperfect, and goes no farther than the seventh section, with a few fragments of the eighth. In it (says Freind) he, with great perspicuity and exactness, illustrates not only Hippocrates, but also several passages of Galen; and observes particularly that the stone increased much in his time, and was less curable; and this he imputes to the luxury of the age, to much eating, and want of exercise (sect. 1, 6, p. 19, ed. Dietz). It was first translated into Latin by J. P. Crassus, and published after his death, Basil. 1581, 4to., in the collection called 'Medici Antiqui Graeci,' &c. The Greek text has lately been published for the first time by F. R. Dietz, in his 'Scholia in Hippocratem et Galenum,' &c., 2 vols. 8vo., Regim. Pruss., 1834. The third work by Palladius is entitled Σχόλια εἰς τὸ περὶ ἀγμῶν Ἱπποκράτους, 'Scholia in Librum Hippocratis de Fracturis.' This also is imperfect, but, in Freind's opinion, what remains is enough to let us see that we have no great loss by it, the text being as full and as instructive as the annotations. They were translated into Latin by Jac. Santalbinus, and are inserted, Gr. and Lat., in the edition of Hippocrates by A. Foesius, Francof. 1595, fol., sect. vi., pp. 196-217; and in that of Hippocrates and Galen by Chartier, tom. xii., pp. 276-288. Dietz, in his preface, mentions another work by Palladius which he found in MS. in the library at Florence, consisting of scholia on Galen's work 'De Sectis,' which he intended to publish, but found the MS. so corrupt, that he was obliged to give it up. Palladius appears to have been well known to the Arabians, as, besides being quoted by Rhazes, he is mentioned among other commentators on Hippocrates by the unknown author of 'Philosoph. Biblioth.,' quoted in Casiri, 'Biblioth. Arabico-Hisp. Escurial.,' t. i., p. 237.

PALLANZA. [NOVARA, VALLE DI.]

PALLAS, the second in order of discovery, and the farthest from the sun, of the new planets. Its motion (for it may have been previously seen and taken for a star) was first observed by M. Olbers of Bremen, March 28, 1802, in making some observations of the stars of Virgo, with a view to future observation of what was then the only new planet, Ceres. The following extract from the Report on Astronomy, made to the British Association by Mr. Airy, will trace the connection of this discovery with those which succeeded it. "One curious consideration was suggested by the comparison of the two orbits (of Ceres and Pallas). Their major axes were so nearly equal (the order of magnitude being sometimes changed by the perturbations of Jupiter), and their orbits approached so near at the intersection of their two planes, that Olbers started the hypothesis of their having been originally parts of a larger planet. If this were true it seemed probable that there might be other parts, and if these were describing orbits round the sun, the intersection of their planes must fall nearly at the same point. By examining the parts of the heavens corresponding to the two intersections, such planets must infallibly be found. On this principle the German astronomers proceeded in a systematic look out for new planets. Olbers in particular examined once in every month a certain portion of the heavens. In September, 1804, Harding discovered Juno, and in March, 1807, after a monthly examination during three years, Olbers discovered Vesta. No others have been found, though the same system of examination was long kept up. In Lindenau's *Zeitschrift*, vol. i., is a notification by Olbers, that he had examined the same parts of the heavens with such regularity that he was certain no new planet had passed between 1808 and 1816. Nothing can give a more forcible idea of the perseverance which led to these discoveries."

The size of Pallas has not been measured with certainty, but it is known to be exceedingly small. On account of its very great inclination to the ecliptic, and eccentricity, it is among the least known of the planets as to the theory of its motion. The elements of its orbit are as follows:

Elements of Pallas's Orbit.

Epoch 1839, October, 14d. 0h. mean astronomical time at Berlin.

Semi-axis major 2·77293, that of the earth being assumed as the unit.

Eccentricity ·24082.

Inclination of the orbit to the ecliptic 34° 37' 28·7''.

Long. of ascending node	172° 39' 31·2''	From the mean equinox of the epoch.
Long. of perihelion	121° 7' 6·8''	
Mean Longitude .	33° 50' 50·2''	

Mean daily sidereal motion 769''·6426.

PALLAS, PETER SIMON, was the son of a surgeon at Berlin, where he was born on the 22nd of September, 1741. He was brought up to the medical profession, and instructed in the natural and medical sciences, in which he made rapid progress. He had also a great talent for learning languages, which he found of advantage to him in after-life. While very young, he imbibed a taste for zoology, and to this science (which became the sole occupation of his future years) he devoted all his leisure while a boy. In 1758 he went to the university of Halle, and he afterwards visited those of Göttingen and Leyden. At Leyden he took his doctor's degree, on which occasion he wrote an inaugural dissertation on intestinal worms. Zoology had now become his ruling passion, and he employed almost all his time in visiting the different museums of natural history, for which Leyden was at that time particularly celebrated. In July, 1761, he came to London for the avowed object of studying medicine, but in reality for the purpose of examining the different collections of animals in this country, and making himself acquainted with the natural productions. He remained in London nearly a twelvemonth. In 1763 he obtained his father's permission to settle at the Hague, where, in 1766, he published his 'Elenchus Zoophytorum,' a work evincing great talent, and which acquired him considerable reputation. The 'Miscellanea Zoologica,' which appeared the same year, further increased the fame of Pallas, and he had appointments offered him by several foreign governments. Among others he attracted the notice of the Empress Catherine, who invited him to St. Petersburg, and offered him the professorship of natural history in the Imperial Academy of Sciences, which he accepted in 1767.

At the time of his arrival in Russia, an expedition, composed of a number of astronomers and other scientific men, was on the eve of setting out, by command of the empress, for the purpose of observing the transit of Venus, and of investigating the natural history and geography of Siberia and the other northern parts of the Russian empire. Pallas gladly accepted an invitation to accompany the expedition, and employed the winter previous to his departure in making the necessary preparations. During this interval he found time however to continue his literary labours, and prepared several numbers of the 'Spicilegia Zoologica' for publication, a work which he had commenced previous to going to St. Petersburg. He also presented his first celebrated memoir to the Academy on the fossil bones of great quadrupeds, which have been so abundantly met with in Siberia. He showed that these bones must be referred to different species of elephant and rhinoceros, and other animals now inhabiting tropical countries.

The expedition set off in June, 1768. The first summer was spent in traversing the plains of European Russia, and the winter was passed at Simbirsk, on the Volga. The next year the expedition visited the borders of Calmuck Tartary, when Pallas carefully examined the shores of the Caspian Sea. They afterwards proceeded through Orenburg, and passed the next winter at Ufa. In 1770 Pallas crossed the Uralian Mountains to Catharinenburg, and, after examining the mines in that neighbourhood, he proceeded to Tobolsk, the capital of Siberia. The year following the expedition reached the Altai Mountains, which run from east to west, forming the southern boundary of Siberia, and, by forming a barrier which obstructs the course of the southerly winds, renders Siberia much colder than many countries in the same degrees of latitude. Thence they proceeded to Krasnoyarsk, on the Yenesei, where they passed the winter; and here they observed the *freezing of mercury*, in 56½° N. lat. The next spring Pallas penetrated across the mountains to the frontiers of China, whence he retraced his steps, and slowly proceeded homewards, visiting Astracan and the neighbourhood of Mount Caucasus on the way back. He reached St. Petersburg in July, 1774, having been absent six years.

Pallas, who was a young and vigorous man when he set out, returned broken down in health, and with his hair whitened from fatigue and disease. Almost all his companions had died; and instead of enjoying the rest which he so much needed, he was obliged to redouble his activity.

in order to arrange their notes and observations as well as his own. The journal which he had kept of his travels, and which he occupied his time in arranging while the expedition was detained in winter-quarters, had been regularly transmitted each year to St. Petersburg, and published on its arrival.

On his return to St. Petersburg, he received many marks of favour from the Empress Catherine. She decorated him with titles, and gave him several lucrative appointments. The office of instructing the grand-dukes Alexander (afterwards emperor) and Constantine in the natural and physical sciences was also entrusted to him. After remaining many years at St. Petersburg, quietly engaged in the pursuits of literature and science, in 1793 and 1794 he took advantage of the conquest of the Crimea to travel through the southern provinces of Russia. He was so much delighted with the climate and productions of the Crimea, that he asked permission of the empress to settle there, hoping to recruit his health. The empress acceded to his request in the most generous manner, giving him a handsome establishment, and a liberal salary to support it. He went to live in the Crimea in 1795, but found that he had been greatly deceived in the climate, which is very variable and sickly. The inhabitants are also barbarous, and he was deprived of all society. His existence was thus rendered very uncomfortable. He lived here however fifteen years, occupied in his researches in natural history. At last he sold his property and quitted Russia. Pallas arrived at Berlin in 1810, after forty-two years of absence: he survived his return a short period only, dying on the 7th September, 1811, at the age of seventy.

Any analysis of the works of Pallas is impossible, for he spent his whole life in the accumulation of facts, which he always related in the simplest manner, leaving the easy task of drawing deductions from them to others. All his writings, of which he left a prodigious number, though written in a dry and uninteresting style, are full of novelties and truths: 'they have placed,' says Cuvier, 'the name of their author in the first rank of naturalists, who are constantly referring to and quoting from every page of them. They are also read and consulted with equal interest by the historian, the geographer, and the student of languages or of nations.' The following is a brief notice of his principal works:—

'Elenchus Zoophytorum,' the Hague, 1766, 8vo.; 'Miscellanea Zoologica,' 4to. Both these works appeared the same year, and were interesting from containing a great deal of information on those little known classes of animals which had been confounded under the name of worms. Pallas showed that the presence or absence of a shell should not form the primary basis of their distribution, but that the analogies of their internal structure ought to be consulted. The 'Elenchus,' which is principally confined to sponges, corallines, &c., is remarkable for the clearness of the descriptions and the care bestowed on the synonyms. The 'Miscellanea' was partly reprinted, with many additions (but with the omission of some of the most valuable parts relating to the invertebrate animals), in the 'Spicilegia Zoologica,' the first four numbers of which were published at Berlin, in 1767.

'Travels through different Provinces of the Russian Empire,' published in German, St. Petersb., 1771-76, 3 vols. 4to. This work contains a great deal of valuable information, but is imperfect, from having been hastily compiled, without access to books of reference, during the author's travels. After Pallas returned to St. Petersburg from his first expedition, he published several interesting papers descriptive of the new and rare quadrupeds which he had met with in Siberia. His account of the musk, the glutton, the gibelline, and the polar bear may be particularly mentioned, which form the four last parts of the 'Spicilegia Zoologica,' and are exceedingly well written. He published a separate volume on the different species of Rodentia that he discovered; it is entitled 'Novæ Species Quadrupedum ex Glirium Ordine,' Erlang., 1778, 4to. The anatomy and history of these animals are excellently described in this work, which is altogether one of his best.

Pallas became a botanist during his travels, and undertook, by desire of the empress, a 'Flora Rossica,' illustrated with magnificent plates, two volumes of which were published at St. Petersburg, in fol., 1784-85; no more appeared.

The last great work which he wrote was a Fauna of the Russian empire, which he intended to embrace all the animals found both in European and Asiatic Russia. He worked at it till his death, and completed the manuscript of the vertebrate animals, which was printed in 3 vols. 4to. at St. Petersburg, in 1811, under the name of 'Zoographia Rosso-Asiatica;' but it was never published till 1831, in consequence of the plates having been mislaid. Some naturalists however managed to obtain copies of the text.

Pallas may be said to have laid the foundation of modern geology in a memoir containing 'Observations on the Formation of Mountains,' which was read to the Academy of St. Petersburg, in 1777, before Gustavus III. of Sweden. 'An attentive consideration of the great mountainous chains of Siberia led Pallas to the discovery of the general law which has since been completely verified, of the succession of the three primitive orders of rocks, the *granitic* in the centre, the *schistous* on their sides, and the *calcareous* externally.'[*] Pallas rendered further service to geology by his second memoir upon the fossil bones of Siberia, published in the 'Novi Commentarii Acad. Petr.' He here related (what was at that time considered as an incredible circumstance) the fact of having found the body of a rhinoceros entire, with the skin and flesh on, imbedded in the frozen ground. The probability and truth of this observation are placed beyond all doubt by the well-known subsequent discovery of the body of an elephant in a mass of ice on the coast of Siberia. [ELEPHANT, *Fossil Species.*]

Pallas wrote a 'History of the Mongolian Nations,' 2 vols. 4to., in German, Petersb., 1776-1801, which is perhaps the most classical account that was ever written of any race of people. He not only treats of the origin and physical character of these people (all usually denominated Tartars), of their manners and government, but also of their religion and languages.

Pallas undertook, by command of the empress, a 'Comparative Vocabulary' of all the languages of the world, two volumes of which were published at St. Petersburg in 1787-1789, in 4to. They contain two hundred and eighty-six words in two hundred languages of Asia and Europe. A third volume, which never appeared, was intended to embrace the languages of Africa and America. The plan of this work (suggested by the empress) was bad, for a simple vocabulary can never give any idea of the mechanism and spirit of a language; it is however of considerable value.

Besides the works already mentioned, Pallas published, among many others, 'Travels through the Southern Provinces of the Russian Empire, in the years 1793 and 1794,' Leipzig, 1801, 2 vols. 4to., in German. There is an English translation of this work, and also of a memoir by Pallas on the different kinds of sheep found in the Russian dominions and among the Tartar hordes of Russia. The latter was translated by James Anderson, the agriculturist.

Pallas was a member of the Royal Society of London, of the Institute of France, and of several other foreign academies, besides that of St. Petersburg; and he wrote many memoirs, which will be found in their different Transactions.

(*Eloge Historique*, by Cuvier; *Biographical Essay on M. Pallas, read to the Academy of Berlin*, by M. Rudolphi, 30th January, 1812.)

PALLAVICINO, SFORZA, son of the marquis Alessandro Pallavicino of Parma, was born at Rome in 1607, studied in the Roman College, and afterwards entered the order of the Jesuits. He wrote a philosophical treatise, 'Del Bene' (on happiness), and another treatise, 'Dello Stilo' (on style in written composition), both of which are esteemed. But the work for which he is best known is the 'History of the Council of Trent' (Istoria del Concilio di Trento, 3 vols., 4to., Rome, 1664), written in defence of the see of Rome against the charges and insinuations brought against it by the celebrated Father Sarpi in his history of the same council. Both works ought to be consulted and compared, in order to form a just opinion of the important transactions to which they refer. Pope Alexander VII. made Pallavicino a cardinal, and employed him in important affairs. His last work was on Christian perfection, 'Arte della Perfezione Cristiana.' Cardinal Pallavicino died in 166

PALLAVICI'NO, FERRANTE, born at Parma in 1615, entered at an early age the order of the Canons of St. Augustin, and made his vows, but after a few years he found that he had acted rashly, and that he was totally unsuited for the life which he had embraced. Having obtained his superior's permission to travel, he repaired to Venice, where he led a life of licentiousness, and wrote obscene books, which found a ready sale. He afterwards went to Germany as chaplain to a nobleman, and returned to Venice just at the time when war broke out between Edoardo Farnese, duke of Parma, and Pope Urban VIII., on the subject of the duchy of Castro. [Farnese.] Pallavicino wrote in favour of his sovereign the duke, using violent expressions against the pope and his nephews the Barberini. One of his pamphlets was entitled 'Il Divorzio Celeste,' by which he intimated that a divorce had taken place between the church and its Divine founder. Pallavicino now thinking he was no longer safe in Italy, resolved to go to France, but unfortunately for him he was accompanied by a young Frenchman of insinuating address, who proved to be a spy of the Barberini, and who led him unawares into the Papal territory of Avignon, where he was immediately seized and led to prison. He was tried for apostasy and high-treason, and was condemned and beheaded on the 5th of March, 1644, at the early age of 28 years. (Poggiali, *Memorie per la Storia Letteraria di Piacenza.*)

---

[*] Cuvier.

PALLE'NE. [Macedonia.]

PALLIAL IMPRESSION. This term is used by conchologists to denote the mark formed in a bivalve shell by the *Pallium* or mantle. It is, normally, found near the margin of the shell, and is, thence, sometimes called the *marginal impression*. In the *Dimyaria*, or bivalves which have two impressions of muscles of attachment, this mark passes from one of those impressions to the other; and if in its passage it bends inwards posteriorly, it is said to be *sinuated*, and the part where this occurs is the *siphonal scar* of Mr. Gray.

PALLIOBRANCHIA'TA, M. de Blainville's name for his first order of his class (the 3rd of the *Malacozoa*) *Acephalophora*.

The following is his definition of the order:—

Branchiæ applied to the internal surface of the lobes of the mantle.

Mouth provided with a pair of long ciliated appendages which are extensible beyond the borders of the mantle, and simulate a kind of arms; termination of the intestinal canal anterior.

Body more or less compressed, comprised between the two pieces of a bivalve shell, one superior, the other inferior, opening anteriorly and articulating posteriorly.

Section I.

Shell symmetrical.

Genera.—*Lingula*; *Terebratula* with its various subsections; *Thecidea*; *Strophomena*; *Plagiostoma*; *Dianchora*; and *Podopsis*.

Section II.

Shell not symmetrical, irregular, constantly adherent.

Genera.—*Orbicula* and *Crania*. [Brachiopoda.]

PALLIUM. [Pall.]

PA'LLIUM (Malacology). [Pallial Impression.]

PALM. [Weights and Measures.]

PALM-OIL. In the article Elæis the Palm has been described, which is the source of the fatty substance commonly known by the name of Palm-oil, and which is imported from the west coast of Africa in considerable quantities. In the year 1833, no less than 220,329 cwts. paid a duty of 27,541*l.*, at the rate of 2*s.* 6*d.* per cwt. Its price has varied from 32*l.* to 24*l.* (duty paid) per ton. In 1839 as much as 272,991 cwts. paid the duty (at 1*s.* 3*d.*), producing 17,062*l.* It has a solid consistence and an orange-yellow colour, and consists of 31 parts of stearin and 69 of elain, besides the principles which give it colour and odour. It is emollient, and is sometimes used in medicine, and also as a liniment in sprains and bruises. It is also employed in the manufacture of soap. The Edinburgh Pharmacopœia mentions Cocos butyracea as the source of Palm-oil, but this is imported from South America, of which part of the world that Palm is a native.

PALM-SUNDAY, the Sunday before Easter, so named because on that day boughs of palm-trees used to be carried in procession, in imitation of those which the Jews strewed in our Saviour's way when he went up to Jerusalem. It is still customary with our boys, in most parts of England, to go out and gather slips with the willow flowers or blossoms at this time; these are selected as representatives of the palm, because they are generally the only plants, at this season, [illegible], in which the power of vegetation can be discovered. Barnaby Googe, in his 'Popish Kingdome,' 4to., Lond., 1570 (a translation from Naogeorgus), alludes to the use of willow branches, at that time, instead of palm.

Stowe, in his 'Survey of London,' tells us that 'in the week before Easter had ye great shewes made for the fetching in of a *twisted tree, or with*, as they termed it, out of the woods into the king's house, and the like into every man's house of honour or worship.' This must also have been a substitute for the palm. An instance of the remote antiquity of this practice in England is afforded by the 'Domesday Survey,' under Shropshire, vol. i., p. 252, 'Terra dimid. vir. Unus reddit inde *fascem buxi in Die Palmarum*.'

The ceremony of bearing palms on Palm-Sunday was retained in England after many other ceremonies were dropped, and was one of those which Henry VIII., in 1539, declared were not to be contemned or cast away. (*Proclam. 26 Feb., 30 Hen. VIII.*) They were borne till 2 Edw. VI. (Stowe's *Chron.*, an. 1548.) These boughs or branches of palm, whatever they might be, underwent a regular blessing. (See the *Missale ad Usum Ecclesiæ Sarisburiensis*, 4to., London, 1555.) Fuller's 'Church History,' p. 222, says, 'Bearing of palms on Palm-Sunday is in memory of the receiving of Christ into Hierusalem a little before his death, and that we may have the same desire to receive him into our hearts.'

The Russians of the Greek church have a very solemn procession on Palm-Sunday.

PALM TREE. [Palms.]

PALMA, GIA'COPO, called the Old, to distinguish him from his great-nephew of the same name, was born at Serinalta, in the territory of Bergamo (though Vasari says at Venice), and is said to have been a disciple of Titian. The dates both of his birth and death are not precisely fixed. Vasari says he died at the age of 48. He had always been considered to be a companion and rival of Lotto, who was born in 1513, till La Combe, on the faith of an apocryphal anecdote of his having finished a picture left imperfect by Titian, who died in 1576, and by other dates, fixes his birth in 1540 and his death in 1588, at the age of 48, as stated by Vasari. But La Combe forgot that Vasari, in his work published in 1568, says that Palma died at Venice, several years before. Palma's manner has much resemblance to that of Titian, whom he chiefly imitated in the softness, as he did Giorgione in the brightness of his colouring, the warm golden tone of which is extremely pleasing. It appears that he had a peculiar manner of laying on his colours, by which he gave the appearance of high finishing without labour.

The paintings of Palma are highly esteemed (though some writers deny him originality) for the noble taste of his composition, for natural and pleasing expression, and the harmony of his colours.

Vasari speaks with high commendation of a picture by Palma representing the ship in which the body of St. Mark was brought from Alexandria to Venice, exposed to the fury of a frightful storm. Other celebrated paintings of his are, a Santa Barbara at Venice, and a St. Jerome in the Zampieri palace at Bologna. The galleries of Vienna, Munich, and Berlin possess several of his works, and there are some in England; among them are a few which are ascribed to Giorgione, but, in the opinion of Dr. Waagen, they are by Old Palma. (Fuseli.)

PALMA GIACOPO, called the Young, was born at Venice in 1544, a date which is alone sufficient to shew the error of La Combe in placing the birth of Old Palma in 1540, as he would then have been only four years older than his great-nephew. Young Palma soon left the style of Antonio his father, an indifferent master, to study the works of Titian, and more especially those of Tintoretto. At the age of fifteen he was taken under the protection of the duke of Urbino, and maintained for eight years at Rome, where, by copying the antique, Michael Angelo, Raphael, and Polidoro, he acquired correctness, style, and effect, which he endeavoured to embody in the first works which he produced after his return to Venice. Some persons conceive that these works combine the best principles of the Roman and Venetian schools. They are executed with a degree of facility, which was the great talent of this master. He did not however succeed in obtaining adequate employment; honour and emolument were engrossed by Tintoretto and Paul Veronese; and he owed the advantage of being considered the third in rank to the patronage of Vittoria, a fashionable architect and sculptor, through whose recommendation he was overwhelmed with commissions, which had the unhappy effect of relaxing his diligence. On the death of his former competitors, when he found himself without a rival, his carelessness increased, and his pictures were little more than sketches: yet when time and price were left to his discretion, he produced works worthy of his former fame, rich in composition, full of beauty, variety, and expression. His tints, fresh, sweet, and transparent, less gay than those of Veronese, but livelier than those of Tintoretto, though slightly laid on, still preserve their bloom. In variety of expression he is not much inferior to either of those masters, and his Plague of the Serpents at St. Bartolomeo may vie with the same subject by Tintoretto in the school of St. Rocco. It is surprising that a man from whom the depravation of style at Venice may be dated, should still have so many charms to attract the eye and interest the heart. Palma died in 1628, aged 84 years. (Fuseli.)

PALMA. [CANARIES.]

PALMA. [MALLORCA.]

PALMA CHRISTI. [RICINUS.]

PALMA NOVA. [UDINE, PROVINCE OF.]

PALMI. [CALABRIA.]

PALMIC ACID. When palmin is treated with solution of potash, it is saponified, and glycerine is separated. When this soap is dissolved in water, and hydrochloric acid is added to it, it is decomposed, and the palmic acid separates.

The properties of this acid are, that when pure it fuses at 122°; the crystals are acicular and colourless; it dissolves in all proportions in alcohol and æther: it reddens litmus paper strongly, and combines with bases to form salts, which are called *palmates*.

Palmate of ammonia is an uncrystallizable salt, and so also is the palmate of soda. Palmate of magnesia is dissolved by alcohol when hot; and as the solution cools, crystalline scales of the salt are deposited. Palmate of lime is soluble also in hot alcohol. Palmate of copper is of a fine green colour; palmate of lead may be obtained in fine silky needles: that of silver is insoluble in alcohol or water.

PALMIN is obtained from castor-oil by treatment with nitric acid containing a portion of nitrous acid. The oil becomes in a few hours of a yellow colour, and is rendered solid; the yellow colour is accidental, pure palmin being white: it is very soluble in alcohol and in æther; it melts at about 150° Fahr. When it has been dissolved in boiling alcohol, it is deposited in small opaline grains as the solution cools.

PALMI'NA, Mr. Gray's name for a genus of Cirrhipedes, differing from *Otion* in having but one auricle.

PALMI'PEDES, Cuvier's name for his sixth order of birds, and thus defined by him:—

Feet formed for natation, that is to say, implanted in the posterior part of the body, articulated to short and compressed tarsi, and palmated or webbed between the toes, are their characteristic. A close-set lustrous plumage saturated with an oily juice, and furnished near the skin with a thick down, defends them from the water on which they live. They are the only birds which have the neck exceeding, sometimes greatly, the length of the feet, a provision accorded to them because, swimming as they do at the surface, they have often to search in the depth below. Their sternum is very long, guarding well the greater part of their viscera, and only having on each side a notch or an oval hole furnished with membranes. Their stomach is generally a muscular gizzard, the cœca are long, and the lower larynx simple, but tumid with cartilaginous capsules in one family.

Cuvier divides his *Palmipedes* into four families. *The Divers* (*Brachypteræ*); the *Longipennes* or *Grands* [illegible]*liers* (Albatrosses, &c.); the *Totipalmes* (Pelicans, &c.); and the *Lamellirostres* (Swans, Geese, Ducks, &c.).

PALMI'PORA, a genus of MADREPORÆA.

PALMS are woody plants, usually trees, with simple stems, inhabiting the warmer parts of the world and especially tropical countries. They constitute a natural order of Endogens most important on account of the many uses to which the species or their products are applied, but in reality nearly allied to the Liliaceous and Juncaceous or Rushy plants of northern countries. Linnæus, who had scarcely any means of judging of the real structure of their fructification, and was therefore uncertain where to station them in his sexual system, placed them in an Appendix by themselves and called them the Princes of Vegetation; it has now however been ascertained that they chiefly belong exandria, Monœcia, and Diœcia.

In general they adhere to the soil by clusters of strong simple roots which not uncommonly form a hillock elevated above the surface of the ground. Their trunks are solid, harder on the outside than the centre, and are sometimes, as in the cane-palms, coated by a layer of siliceous matter; they are usually quite simple, growing exclusively by a single terminal bud, called in the Areca its cabbage, and eaten as a delicacy when boiled; but in the Doom Palm, or Hyphæne, they are regularly forked. In the majority of the order the stem is nearly cylindrical, but in some it is thickest at the base, and in others swollen in the middle; occasionally it is defended by strong hard spines, but is more frequently unarmed, and marked by rings which indicate the places whence the leaves fall off.

The leaves, called fronds by Linnæus, are alternate, with a very hard epidermis, and a distinct petiole, from the base of which a coarse network, called the reticulum, sometimes separates next the trunk; they are usually either pinnated or fan-shaped, but are occasionally nearly split in two; their veins are parallel, the spaces between them plaited, and the whole size sometimes very great, as in the fan-palm, in which specimens have been seen as much as 18 or 20 feet in breadth. [CORYPHA.]

The flowers appear in panicled spikes from the inside of hard dry spathes, which are often boat-shaped, and although small, they are sometimes so extremely numerous that each panicle will weigh many pounds. They are generally hermaphrodite, but often monœcious, diœcious, or polygamous. The calyx and corolla consist each of three pieces, which are either distinct or more or less united. The stamens vary in number, from 3 to a large multiple of that number, and bear 2-celled linear anthers which open along their inner face. The ovary consists of 3 carpels, which are sometimes distinct, sometimes consolidated, and occasionally in part abortive, so that the ovary is only one-celled. The ovaries are almost always solitary, and erect in each cell, but sometimes two are present, which in that case stand side by side; they are orthotropous in some genera and anatropous in others. The styles are very short, the stigmas simple.

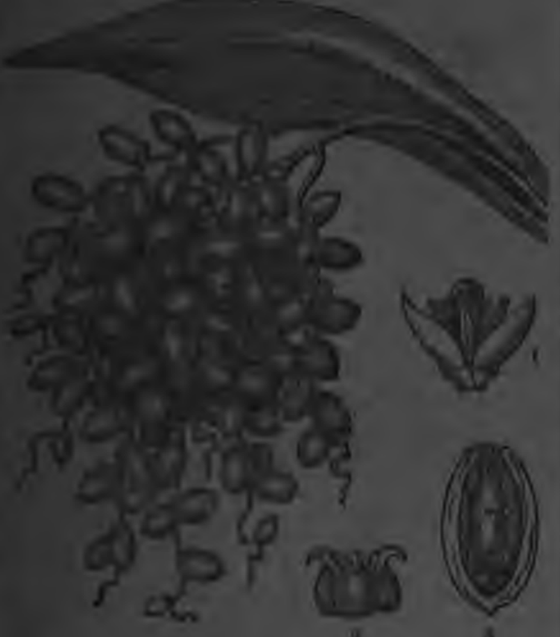
The fruit varies extremely in its consistence and appearance. Sometimes it is 3-celled, often one-celled; in such species as the Cocoa-nut it is a kind of drupe covered by a course fibrous rind; in others it is a soft sweet eatable pericarp, as in the date; in others its surface is broken up into lozenge-shaped spaces, as in the Sagus, whose fruit looks as if covered with scale-armour. The seed is single, either solid or hollow, and consists principally of albumen of a fleshy, oily, horny, or cartilaginous texture, within which is lodged a very small cylindrical embryo at some part of the surface distant from the hilum.

That palms were among the first land-plants which were created, is proved by the numerous remains of their fruit and leaves which occur in the coal formations; and remains of them are occasionally met with through all the more recent fresh-water rocks. They appear to prefer a soil in some measure salt, although many species are inhabitants altogether of inland districts and even of high mountains. Their geographical limits appear to be within 36° N. lat. in America, 44° N. lat. in Europe, 34° N. lat in Asia, and 38° S. lat. in the southern hemisphere; and, according to Von Martius, their powers of migration are extremely small; none of them have been able to cross the ocean without the aid of man. Their favourite stations are said to be the banks of rivers and watercourses, and the sea-shore, some species scattered singly and others collected together into large forests.

There is scarcely a species of this order in which some useful property is not found. The cocoa-nut, the date, and others are valued for their fruit; the fan-palm and many more, for their foliage, whose hardness and durability renders it an excellent material for thatching; the sweet juice of the palmyra [BORASSUS] when fermented yields wine; the centre of the Sago-palm abounds in nutritive starch; the trunk of the Iriartea or Ceroxylon exudes a valuable vegetable wax; oil is expressed in abundance from the oil-palm; an astringent matter resembling dragon's blood is produced by Calamus Draco; many of the species contain within their leaves so hard a kind of fibrous matter, that it is employed instead of needles, or so tough that it is manufactured into cordage; and finally, their trunks are in some cases valued for their strength and used as timber, or for their elasticity, or their flexibility, as in the cane-palm.

The number of species is estimated at about 1000, divided into 61 genera distributed through 5 tribes.

(Martius, *Palmarum Familia ejusque Genera denuò illustrata*; also the *Genera and Species Palmarum* of the same author; Endlicher's *Genera Plantarum*, p. 244; and Lindley's *Natural System of Botany*, ed. 2, p. 343.)



A. Branch of fruit of the Phœnix Dactylifera, or Date-Palm, with the spathe from which they sprang. 1. A separate flower. 2. The ovary. 3. A section of the fruit, containing a horny seed, in the middle of whose back is seen a pit, which conceals the seat of the embryo.

PALMELLA'RIA, a genus of Polyparia Membranacea.

PALMYRA, TADMOR. Both these names are derived from the palm-trees which once grew in the neighbourhood of this ancient city. Palmyra is situated in an oasis of the Syrian desert, nearly half-way between the Orontes and the Euphrates, and about 140 miles east-north-east of Damascus, in 34° 24′ N. lat. and 38° 20′ E. long., according to Major Rennell. (*Comparative Geography of Western Asia.*)

The circumstance of Palmyra being situated in an oasis sheltered by hills to the west and north-west, and supplied with wholesome water, and on a line leading from the coast of Syria to the regions of Mesopotamia, Persia, and India, must have pointed it out in very early times to the caravans as a convenient halting-place in the midst of the desert. The Phœnicians were probably early acquainted with it, and may have suggested to Solomon, with whom the king of Tyre was in alliance, the idea of establishing an emporium there. We read in the Second Book of *Chronicles* (viii. 4), that Solomon "built Tadmor in the wilderness, and all the store cities which he built in Hamath." Hamath was a town and territory extending along the banks of the Orontes, and bordering on the Syrian desert. After this we read no more of Tadmor in the Scriptures, but John of Antioch, probably from some tradition, says that it was destroyed by Nebuchadnezzar. The first notice which we have of it in Roman history is that M. Antony, being in Syria, marched to plunder it, expecting a rich booty, but the inhabitants disappointed him by transporting their goods beyond the Euphrates.

In the time of Pliny it was the intermediate emporium of the trade with the East, a city of merchants and factors, connected with the Parthians on one hand and the Romans on the other. The produce of India found its way to the Roman world through Palmyra. It afterwards became subject to the empire as a free state, and was greatly favoured by Hadrian and the Antonines, under whom it attained its greatest splendour.

Odenatus, a native of Palmyra, having rendered great services to the Roman empire in a war against the Persians, received, with the consent of Gallienus, the title of king of Palmyra, and Gallienus conferred upon him the command of all the forces in the East. Odenatus obtained several victories over the Persians, but being at last treacherously killed, his wife Zenobia, an aspiring woman, assumed the crown, and styling herself Queen of the East, asserted her sovereignty over Mesopotamia and Syria.

The confusion into which the empire was thrown by domestic dissension and the numerous aspirants to the throne left Zenobia undisturbed for several years, during the latter part of the reign of Gallienus and the subsequent reign of Claudius. But after Aurelianus was proclaimed emperor, he resolved to put down Zenobia, who had extended her conquests over part of Asia Minor. Aurelian soon recovered that province, and defeated Zenobia's troops near Antioch, and afterwards at Emesa, in a great battle in which the queen commanded in person. Zenobia retired to Palmyra, which appears to have been strongly fortified, as it required a long siege and a number of military engines to reduce it. Zenobia endeavoured to escape towards the Euphrates, but was overtaken by the soldiers of Aurelian and made prisoner. Palmyra then surrendered, and Aurelian left a garrison in it. He put to death several of the chief officers of Zenobia, and among others her minister, the philosopher Longinus. After some time the people of Palmyra revolted, and killed the Roman garrison. Aurelian, on receiving information of it in Thrace, marched quickly back to Syria, and having entered Palmyra without resistance, directed an indiscriminate slaughter of the inhabitants. This is averred by his own letter to Probus, whom he appointed governor of the place, and which has been preserved by Vopiscus. Zenobia appeared as a captive in the triumphal procession of Aurelian at Rome, after which she was allowed to reside at a country-house near Tibur, where she spent the remainder of her life. Syncellus says that she married a Roman senator, and had children by him. A Latin inscription at Palmyra, copied by Wood and Dawkins, shows that the place was garrisoned by the Romans under Diocletian, who built or restored several edifices. Justinian is mentioned by Procopius as having fortified Palmyra and placed a garrison in it. The Moslems took it under the caliphate of Abu Bekr, Mohammed's successor. (Ockley, *History of the Saracens.*) We hear no more of Palmyra after this till the twelfth century, when Benjamin of Tudela visited it. He says it was encompassed by a wall, and that there were in it 2000 Jews, valiant and prepared for battle, who make war with the children of Edom and the children of Hagar or the Arabians (the Agarenes of the Christian historians of the middle ages), subject unto the kingdom of Noraldinus, and they help the bordering Ishmaelites. Among them Isaac, surnamed Græcus, and Nathan and Uziel, have the pre-eminence. (Purchas, ix. ch. 5.) The latest historical notice of Palmyra is its plunder in 1400 by the army of Tamerlane. It has been in a ruined and desolate state for centuries past, and the spot is inhabited by a small tribe of Bedowin Arabs, who have built their hovels in the peristyle of the great temple.

The first appearance of Palmyra is very striking. Its innumerable columns and other ruins, extending nearly a mile and a half in length and unobstructed by modern buildings, contrast by their snow-white appearance with the yellowish sand of the desert. But, examined separately, few of these remains can be called beautiful as works of art. The largest columns do not exceed 4 feet in diameter and 40 feet in height. There is a great sameness in the architecture, all the columns being Corinthian, with the exception of those which surround the temple of the Sun, which are Ionic and fluted. (Irby and Mangles, *Travels in Syria, &c. in 1817-18.*) Upon the whole, the ruins of Palmyra are inferior in grandeur and style to those of Baalbek. The most interesting remains of Palmyra are perhaps its sepulchres, which are outside of the walls of the ancient city, and are built in the shape of square towers, from three to five stories high, each forming a sepulchral chamber, with recesses divided into four or five compartments for the reception of the dead bodies. Some of the chambers are ornamented with sculptures and fluted Corinthian pilasters, and the walls are stuccoed white. The ceiling, on which the paint is still perfect, is ornamented like that of the peristyle of the temple of the Sun at Baalbek, with the heads of various deities disposed in diamond-shaped divisions. Remains of mummies and mummy-cloths are found resembling those of Egypt. The lines of the streets and the foundations of the houses are distinguishable in some places. Small rows of columns denote the areas of the open courts of private houses, as at Pompeii. The inscriptions found at Palmyra are either Greek or Palmyrene, with the exception of one in Hebrew and one or two in Latin. On the inscriptions of Palmyra see the work 'Inscriptiones Græcæ Palmyrenorum cum Annotationibus Edw. Bernardi et Thomæ Smithi,' Utrecht, 1698, and that of the orientalist Father Giorgi, 'De Inscriptionibus Palmyrenis quæ in Musæo Capitolino adservantur interpretandis Epistola,' Rome, 1782. Giorgi makes out a Palmyrene alphabet, which Barthélemy had attempted to do before him, but not successfully. The antient commerce of Palmyra has been discussed by Heeren. (*Journal of Education*, vol. ii., and the references there given.)

Wood and Dawkins visited Palmyra about the middle of the last century, and published a description of its remains, with plates, folio, London, 1758. Since that time Volney, Cassas, Bankes, Irby, and other travellers have visited the same.

PALMY'RA (Zoology), Savigny's name for a genus of *Dorsibranchiate Annelids*, distinguishable by their upper fasciculæ, the bristle-like or hair-like processes forming which are large, flattened, disposed in a fan-shape, and brilliant as polished gold. Their cirrhi and branchiæ are but little marked. Their body is elongated, and they have two rather long and three very small tentacles.

The only species known is *Palmyra aurifera*, Sav.

Locality.—Seas of the Isle of France.

PALMYRA, a name applied by the Europeans in India to the stately palm called by botanists *Borassus flabelliformis*. [Borassus.] This by the Hindus is called *Tal* and *Tar*, whence its sap is named *taree*, and this being fermented to produce a spirit, has given origin to the toddy of Europeans. This tree is common in the islands of the Eastern Archipelago and the southern parts of India, and extends even as far north as 30° of N. latitude. Its leaves are employed in making fans and punkahs, and also in thatching: the fruit is eaten: the sap is drank in its natural state, and forms a refreshing beverage, or is evaporated to make *jagury*, or coarse sugar; but if fermented, it forms one of the intoxicating liquors of tropical countries. This tree often presents a very remarkable appearance, that of growing apparently out of the centre of the banyan tree (*Ficus indica*). This has been well explained by Dr. Roxburgh: the seed of the latter, having been eaten by birds, is by them frequently deposited on the moist upper parts of the leaves and spathes of the Palmyra tree, where germinating, it soon sends down its descending shoots or roots, which, in course of time, entirely encircle the palm. This finally appears with only its bunch of leaves projecting beyond the trunk of the banyan-tree, out of which it appears to be growing, though actually older, and, like it, having its roots fixed in the ground.

PALO DE VACA. [Cow-tree.]

PALOMI'NO Y VELASCO, DON ACISLO ANTONIO, an eminent Spanish painter, was born in 1653 (some say 1658), at Bujalance, near Cordova, in the university of which city he became a student, but his predilection for the arts induced him to take instruction in painting from Don Juan de Valdes Leal, in whose company he went in 1678 to Madrid to make himself acquainted with the styles of different schools. He was introduced to king Charles II. by the celebrated Coello, and obtained through the friendship of Carenno a commission to paint the gallery Del Ciervo. He painted the history of Psyche so entirely to the king's satisfaction that he gave him the title of his principal painter and a considerable pension. He obtained such numerous commissions, that notwithstanding his extraordinary industry, he was often unable to do more than furnish the design, leaving it to be finished by his pupil Dionisco Vidal. His reputation continued to increase, and all his works, which he executed at Valencia, Salamanca, Granada, and Cordova, to which cities he was successively invited, were highly approved. It has been a reproach to him that among some of his grandest works, such as the Confession of St. Peter, in the cathedral of Valencia, and those in the cathedral of Cordova, his figures are too faithful transcripts of ordinary life. What he executed himself, whether in oil or in fresco, is distinguished by invention and drawing, and his perspective and colouring are admirable. He died at Madrid, April 13, 1726.

Palomino is the author of a work in three parts, theoretical, practical, and biographical. The first two bear the title of 'El Museo pictorico y Escala optica.' The third part, 'El Parnaso Español pictorico, tomo terceiro,' Madrid, 1724, though perhaps only intended as an appendix to the two others, is by far the most important and interesting. He may be considered, says Fuseli, as the Vasari of Spain, as copious, as credulous, as negligent of dates, too garrulous for energy, too indefinite for the delineation of character, but eminently useful with the emendations of modern and more accurate biographers.

PALOS, a little port of Andalucia, on the south-western coast of Spain, has become celebrated as the spot whence Columbus sailed on his first voyage of discovery on the morning of the 3rd of August, 1492. [Columbus.] Previous to this, the port of Palos had been condemned, owing to some dismeanour of its inhabitants, to maintain two caravels for a twelvemonth for the public service, and it was to this circumstance that it owed, what afterwards proved the honour, of furnishing the vessels employed in the discovery of the New World. The town, which at all times was very small, now contains 1100 inhabitants, whose only trade consists of wine, brandy distilleries for the consumption of Seville, and wood from the pine-forests in the neighbourhood. The only remarkable building is a convent, formerly a temple consecrated to Proserpine, and which, during the middle ages, was occupied by the knights of the Temple.

(Miñano, *Diccionario Geografico de España y Portugal*, vol. vi.; Navarrete, *Coleccion de Viages*, vol. ii.; Muñoz, *Hist. del Nuevo-Mundo*.)

PALSY. [Paralysis.]

PALUDI'NA (Malacology). [Peristomiana.]

PALY'THOA, a genus of zoophytic animals allied to Alcyonium. [Zoantharia.]

PAMIERS, the chief town of an arrondissement in the department of Ariège or Arriège in France. It is situated in the valley of the Arriège, and on the right bank of that river, about 10 miles north of Foix, the capital of the department, and about 40 miles south by east of Toulouse. Pamiers was known in the middle ages by the name of Fredelas or Fredelatum, and it ranked as the capital of the county of Foix. The town is of middling size; and though the streets are well laid out, the houses are ill built. There is a cathedral, said to have been built from the designs of the architect Mansard; also a small theatre. The population, in 1831, was 5150 for the town, or 6048 for the whole commune; in 1836, it was 6905 for the commune. The chief manufactures are of steel, files, scythes, ordinary woollen cloth, and cotton and woollen yarn; the wool employed is Spanish. There are eight yearly fairs. Considerable trade in corn is carried on. The environs of the town are rich in corn, fruit, and pasturage. Pamiers is the seat of a bishopric, the bishop is a suffragan of the archbishop of Toulouse; his diocese comprehends the department. There are in the town a subordinate court of justice and a high school. There is a chalybeate spring in the neighbourhood, which is considered to be serviceable for chronic disorders.

The arrondissement of Pamiers comprehends the northern part of the department, and is divided into six cantons or districts, each under a justice of the peace: it comprehends 115 communes, and had, in 1831, a population of 73,753.

PAMPAS. [Plains.]

PAMPELU'NA, or PAMPLO'NA. [Navarra.]

PA'MPHILUS was a native of Amphipolis (Suidas, *Apelles*), but he studied his art under Eupompus of Sicyon, and succeeded in establishing the school which his master founded. Eupompus was a native of Sicyon and the founder of the Sicyonian school of painting. He introduced a new style of art, and added a third, the Sicyonic, to the till then only acknowledged two distinct styles of painting, known previously as the Helladic and the Asiatic, but subsequently to Eupompus as the Attic and the Ionic. These two styles, with the Sicyonic, henceforth formed the three characteristic styles of Grecian painting. (Pliny, xxxv. 10, 36.) Through his pupil Pamphilus, Eupompus established those principles of art which Euphranor, Apelles, Protogenes, and Aristides successfully developed.

The characteristics of the Sicyonic school were, a stricter attention to dramatic truth of composition, and a finer and a more systematic style of design. The leading principles of Eupompus were, that man should be represented as he actually appears, not as he really is, and that nature herself was to be imitated, not an artist. (Pliny, xxxiv. 8, 19.) Such was the answer which Eupompus gave to Lysippus, upon being asked by him which of his predecessors he should imitate.

Pamphilus succeeded Eupompus in the school of Sicyon, and taught his principles to Apelles. He was, says Pliny (xxxv. 36, 8), the first painter who was skilled in all the sciences, 'omnibus litteris eruditus,' particularly arithmetic and geometry, without which he denied that art could be perfected. By arithmetic and geometry we must understand those principles of the art which can be reduced to rule: by arithmetic, the system of the construction and the proportions of the parts of the human body; by geometry, perspective and optics, at least so much of them as is necessary to give a correct representation of and a proper balance to the figure. Flaxman properly explains the terms by the rules of proportion and motion; he remarks, 'How geometry and arithmetic were applied to the study of the human figure, Vitruvius informs us from the writings of Greek artists, perhaps from those of Pamphilus himself: "a man," says he, "may be so placed with his arms and legs extended, that his navel being made the centre, a circle can be drawn round touching the extremities of his fingers and toes. In the like manner a man standing upright, with his arms extended, is enclosed in a square the extreme extent of his arms being equal to his height."' Flaxman remarks also, that 'it is impossible to see the numerous figures springing, jumping, dancing, and falling in the Herculaneum paintings on the painted vases, and the antique basso-relievos, without being assured that the painters and sculptors must have employed geometrical figures to determine the degrees of curvature in the body, and angular or rectilinear extent of the limbs, and to fix the centre of gravity.'

Such was the authority of Pamphilus, says Pliny (xxxv. 10, 36), that chiefly through his influence, first in Sicyon and then throughout all Greece, noble youth were taught the art of drawing before all others; it was considered amongst the first of liberal arts, and was practised exclusively by the free-born, for there was a law prohibiting all slaves the use of the cestrum or graphis (γραφίς).

In this school of Pamphilus, the most famous of all the schools of antient painting, the progressive courses of study occupied the long period of ten years, comprehending instruction in drawing, 'arithmetic,' geometry, anatomy, and painting in its different branches. The fee of admission was no less than a talent (Pliny, xxxv. 10, 36); a large fee, for the Attic talent, which is most probably here alluded to, was about 219*l.* sterling. Pliny mentions that Apelles and Melanthius both paid this fee. Apelles studied under Ephorus of Ephesus before he entered the school of Pamphilus at Sicyon. Pausias of Sicyon also studied encaustic under Pamphilus, but Pliny does not inform us whether he belonged to his school and paid the above-mentioned fee.

Pamphilus, like his master Eupompus, seems to have been occupied principally with the theory of art and with teaching, for we have very scanty notices of his works. Yet he and his pupil Melanthius, according to Quintilian (xii. 10), were the most renowned amongst the Greeks for composition. We have accounts of only four of his paintings, the 'Heraclidae,' mentioned by Aristophanes (*Plutus*, 385), and three others mentioned by Pliny—the Battle of Phlius and Victory of the Athenians, Ulysses on the Raft, and a relationship, 'cognatio,' probably a family portrait; these pictures were all conspicuous for the scientific arrangement of their parts, and their subjects certainly afford good materials for fine composition.

The period of Pamphilus is sufficiently fixed by the circumstance of his having taught Apelles, and he consequently flourished somewhat before and about the time of Philip II. of Macedon, from B.C. 388 to about B.C. 348. He left writings upon the arts, but they have unfortunately suffered the common fate of the writings of every other antient writer. He wrote on painting and famous painters.

PAMPHILUS was bishop of Caesarea in Palestine, and the intimate friend of Eusebius, who was called Pamphili after him. [EUSEBIUS.] He is said to have been born at Berytus, and to have been educated by Pierius. He spent the greater part of his life in Caesarea, where he suffered martyrdom in the year 309.

He was a man of profound learning, and devoted himself chiefly to the study of the Scriptures and the works of Christian writers. Jerome states that he wrote out with his own hand the greater part of Origen's works. He founded a library at Caesarea, chiefly consisting of ecclesiastical works, which became celebrated throughout the Christian world. It was destroyed before the middle of the seventh century. He constantly lent and gave away copies of the Scriptures. Both Eusebius and Jerome speak in the highest terms of his piety and benevolence.

Jerome states that Pamphilus composed an apology for Origen before Eusebius; but at a later period having discovered that the work which he had taken for Pamphilus's was only the first book of Eusebius's apology for Origen, he denied that Pamphilus wrote anything except short letters to his friends. The truth seems to be that the first five books of the 'Apology for Origen' were composed by Eusebius and Pamphilus jointly, and the sixth book by Eusebius alone, after the death of Pamphilus. Another work which Pamphilus effected in conjunction with Eusebius was an edition of the Septuagint, from the text in Origen's 'Hexapla.' This edition was generally used in the Eastern church. Montfaucon and Fabricius have published 'Contents of the Acts of the Apostles' as a work of Pamphilus; but this is in all probability the production of a later writer.

Eusebius wrote a 'Life of Pamphilus,' in three books, which is now entirely lost, with the exception of a few fragments, and even of these the genuineness is extremely doubtful. We have however notices of him in the 'Ecclesiastical History' of Eusebius (vii. 32), and in the 'De Viris Illustribus' and other works of Jerome. (Lardner's *Credibility*, part ii., c. 59, and the authorities there quoted.)

PAMPHY'LIA (*Παμφυλία*), a province of Asia Minor, formerly called Mopsopia according to Pliny (*Hist. Nat.*, v. 26), extended along the coast of the Mediterranean from Olbia to Ptolemais* (a distance of 640 stadia according to Strabo, xiv., p. 667): it was bounded on the north by Pisidia, on the west by Lycia and the south-western part of Phrygia, and on the east by Cilicia. Pamphylia was separated from Pisidia by Mount Taurus, and was drained by numerous streams which flowed from the high land of Pisidia. The eastern part of the coast is described by Captain Beaufort as flat, sandy, and dreary, but this remark does not apply to the interior of the country, which, according to Mr. Fellows's account (*Excursion in Asia Minor*, p. 204), is very beautiful and picturesque. The western part of the coast is surrounded by lofty mountains, which rise from the sea and attain the greatest height in Mount Solyma on the eastern borders of Lycia. The western part of the country is composed, according to Mr. Fellows (p. 194), 'for thirty or forty miles, of a mass of incrusted or petrified vegetable matter, lying embosomed, as it were, in the side of the high range of marble mountains which must originally have formed the coast of this country. As the streams, and indeed large rivers, which flow from the mountains, enter the country formed of this porous mass, they almost totally disappear beneath it; a few little streams only are kept on the surface by artificial means, for the purpose of supplying aqueducts and mills, and being carried along the plain, fall over the cliffs into the sea. The course of the rivers beneath these deposited plains is continued to their termination at a short distance out at sea, where the waters of the rivers rise abundantly all along the coast, sometimes at the distance of a quarter of a mile from the shore.'

The Pamphylians, according to Herodotus (vii. 91), were descendants of the people who followed the fortunes of Amphilochus and Calchas after the destruction of Troy. They were subdued by Croesus (Herod., i. 28), and afterwards formed part of the Persian empire, and supplied Xerxes with thirty ships in his expedition against Greece (Herod., vii. 91). We know very little of the history of this province, and it is not improbable, considering its proximity to Pisidia [PISIDIA], that its dependence on the Persian empire was oftentimes merely nominal. Under the Syrian kings it formed a separate province including Pisidia; and the same appears to have been the case under the Roman empire, though it seems to have been sometimes united to the province of Galatia. (Tac., *Hist.*, ii. 9.)

Though Pamphylia was of small extent, it contained several towns of considerable importance. Olbia, the first town on the west, is described by Strabo (xiv., p. 667) as a strongly fortified place on the coast; and beyond it, on the western bank of the Catarractes (*Duden*), was Attalia (*Adalia*), founded by Attalus Philadelphus, king of Pergamus. This city was visited by St. Paul in his road from Perge to

---

* Pliny (*Hist. Nat.*, v. 26) and Mela (i. 14) make Pamphylia begin at Phaselis, which they reckon a city of Pamphylia; but the majority of writers speak of it as a Lycian city. Livy says that it was the boundary of Lycia and Pamphylia ('in confinio Lyciae et Pamphyliae est,' xxxvii. 23).

Antioch (*Acts*, xiv. 25, 26). Mr. Fellows, who visited Adalia in 1838, speaks of it as a small but clean town, built on a cliff which rises sixty or eighty feet above the sea, and informs us (p. 187) that it contains numerous fragments of antient buildings, columns, inscriptions, and statues, which are generally built into the walls of the town with care and some taste.

East of Attalia, and 60 stadia from the coast, on the Cestrus (*Asku*), was Perge, in the neighbourhood of which was a celebrated temple of the Pergæan Artemis, at which a sacred meeting (πανήγυρις) was held every year (Cic. *in Verr.*, i. 20; Strabo, p. 667). Perge was visited twice by St. Paul; first, when he came from Paphos in Cyprus (*Acts*, xiii. 13), and the second time, on his road from Pisidia (*Acts*, xiv. 24, 25). Perge was situated between and upon the sides of two hills, with an extensive valley in front, and backed by the mountains of the Taurus. (Fellows, p. 191.) It contains several antient ruins; of which the principal are, a large theatre, of the width of 330 feet, a stadium, or course for races, and two or three temples. The next town which we come to is Aspendus, on the Eurymedon, at the distance of 60 stadia from the sea (Strabo, p. 667); the greater part of which was built on a precipitous rock (Arrian, i. 26). It appears to have been a place of considerable importance in the time of Alexander, who punished the inhabitants severely for refusing to contribute fifty talents and supply him with the horses which they had been accustomed to rear for the king of Persia. (Arrian, i. 26, 27.) Under the Seleucidæ it was able to send 4000 men against Selge, a town of Pisidia (Polyb., v. 73, s. 3); and Cicero speaks of it in his time as an antient and noble city, full of works of art (Cic. *in Verr.*, i. 20). The site of Aspendus is doubtful. Most modern maps place the modern village of Starus upon what is usually supposed to be the position of Aspendus; but Mr. Fellows states that no remains of antiquity are to be heard of in the neighbourhood. East of Aspendus, and beyond the Melas, was Side (*Eski*), which was founded by the Æolian Greeks of Cuma in Mysia; but the inhabitants, according to Arrian (i. 26), did not speak Greek. The ruins of Side, which contain a large theatre, have been described both by Captain Beaufort and Mr. Fellows, but they are far inferior to the ruins of most of the other cities of Pamphylia.

PAN, a deity of the Greek mythology, whose country was Arcadia. He was the tutelar god of the shepherds. Pan is represented with two horns, a goat's beard, a goat's tail, and goat's feet, holding the syrinx, a kind of musical pipe, which he was said to have invented. The satyrs are his attendants. Pan is mentioned in the early mythi as having been present at the battle of the Titans, whom he assisted in routing by frightening them by a wild noise which he produced by blowing in a sea-shell. He was also said to have accompanied Bacchus to India, and that upon one occasion, by uttering a loud scream, which was repeated by the echoes, he scared away the enemy. From these incidents the expression 'panic fear,' meaning a terror produced by no obvious or sufficient cause, appears to have been derived. Pan was worshipped at Athens and other Greek cities. His worship was introduced into Italy at an early period, where he was also called Inuus; and festivals, called Lupercalia, were instituted in honour of Pan Lupercus, the protector of the flocks against wolves. According to Servius (note to Virgil's 'Eclogues,' ii. 31) Pan was also considered as the god of Nature, a personification of the universe, the word *pan* (πᾶν), in Greek, meaning 'all,' or 'the whole.'

PAN, the Hindu name of the leaf of the betle pepper. [PIPER BETLE.]

PANÆNUS of Athens, the brother or the nephew of Phidias, the former according to Pliny and Pausanias, the latter according to Strabo, was one of the first of the Greeks who attained to any great excellence in painting; but he has been very improperly termed by some the Cimabue of the Greeks, for although the contemporary, he was many years the junior of Polygnotus, Micon, and Dionysius of Colophon, who had all deservedly attained the greatest fame in Athens considerably before his time.

Panænus assisted Phidias in decorating the Olympian Jupiter, but his most famous work was the 'Battle of Marathon' in the Pœcile at Athens; it contained the Iconics or portrait figures of Miltiades, Callimachus, Cynægirius, generals the Athenians, and of Datis and Artaphernes, generals of barbarians (Pliny, xxxv. 8, 34); their respective names were not attached to the figures in this instance (Æschines 'Against Ctesiphon'), that having already become an antiquated custom. These Iconics have been considered to signify portraits in the fullest sense of the term, but the picture of Panænus cannot have been painted much less than 40 years after the battle of Marathon took place, and nearly as many after the deaths of most of the above-named generals; for the Pœcile was built by Cimon in the 3rd year of the 77th Olympiad, 20 years after the battle of Marathon; the Olympian Jupiter was painted in the 86th, 35 years later, and Pliny mentions the 83rd as the period of Panænus. The portraiture therefore, unless taken from earlier pictures, which is very improbable, must in this instance have been confined to the costume and decorations of generals as known to have been worn by them upon the occasion; and the 'Iconics' consequently, whether paintings or statues, although sometimes portraits in countenance as well as in figure, were apparently not necessarily so.

The painting of the Battle of Marathon was in four great divisions; the first represented the positions of the two armies before the battle, the second and third the principal incidents during the battle, and the fourth the total rout and flight of the Persians; each in itself an extensive composition and forming an independent picture. (Pausanias, i. 15.) It appears that Micon assisted Panænus in painting these pictures, and was fined 30 minæ (108*l.*), for having painted the barbarians larger than the Greeks.

The paintings and decorations of the Olympian Jupiter by Panænus were on the throne and on the wall around the throne of the statue. (Strabo, viii. p. 354.) The subjects of the paintings were, Atlas supporting Heaven and Earth, with Hercules near him about to relieve him from his burden; Theseus and Peirithous; figures representing Greece and Salamis, the latter bearing the rostra of a ship in her hands; the Combat of Hercules with the Nemean Lion; Ajax and Cassandra; Hippodamia, the daughter of Œnomaus, with her mother; Prometheus chained, and Hercules preparing to destroy the vulture which preyed upon him; and Penthesilea dying, supported by Achilles, with Hesperian nymphs bearing fruit. (Pausanias, v. 11.)

Pliny tells us that Panænus painted the interior of the temple of Minerva at Elis with milk and saffron; he painted also the inside of Minerva's shield, but in what manner we are not informed.

Already in the time of Panænus prize contests were established at Corinth and Delphi, in one of which he was defeated by Timagoras of Chalcis at the Pythian games (Pliny, xxxv. 9, 35.) Although this is the only notice we have of Timagoras, he must have been a painter of considerable merit, from this single circumstance. He himself celebrated his own victory in verse.

PANÆTIUS, a Greek philosopher, was a native of Rhodes. He studied at Athens, under Diogenes the Stoic, and afterwards came to Rome, about 140 B.C., where he gave lessons of philosophy and was intimate with Scipio Æmilianus, the younger Lælius, and Polybius. After a time Panætius returned to Athens, where he became the leader of the Stoic school, and where he died at a very advanced age. Posidonius, Scylax of Halicarnassus, Hecaton, and Mnesarchus are mentioned among his disciples. Panætius was not apparently a strict Stoic, but was rather an Eclectic philosopher who tempered the austerity of his sect by adopting something of the more refined style and milder principles of Plato and the other earlier Academicians. (Cicero, *De Finibus*, iv. 28.) Cicero, who speaks repeatedly of the works of Panætius in terms of the highest veneration, and acknowledges that he borrowed much from them, says that Panætius styled Plato 'the divine' and 'the Homer of philosophy,' and only dissented from him on the subject of the immortality of the soul, which he seems not to have admitted. (*Tuscul. Quæst.*, i. 32.)

Aulus Gellius (xii. 5) says that Panætius rejected the principle of apathy adopted by the later Stoics, and returned to Zeno's original meaning, namely, that the wise man ought to know how to master the impressions which he receives through the senses. In a letter of consolation which Panætius wrote to Q. Tubero, mentioned by Cicero (*De Finibus*, iv. 9), he instructed him how to endure pain, but never laid it down as a principle that pain was not an evil. He was very temperate in his opinions, and he often replied to difficult questions with modest hesitation, saying ἐπέχω, 'I will consider.'

None of the works of Panætius have come down to us, but their titles and a few sentences from them are quoted by Cicero, Diogenes Laertius, and others. He wrote a treatise 'On Duties,' the substance of which Cicero merged in his own work 'De Officiis.' Cicero says that Panætius had divided his subject into three parts: the first treated of those cases in which men deliberate between what is honest and what is dishonest; the second, concerning what is useful and what is disadvantageous; and the third, of those cases in which the useful is opposed to the honest; that he treated the two first in a masterly manner, but did not go on with the third part, although he had promised to do so, and though he lived for thirty years after he had composed the others. His disciple Posidonius supplied in some degree the deficiency. (*De Officiis*, iii. 2, and *Epist. ad Att.*, xvi. 11.)

Panætius wrote a treatise 'On Divination,' of which Cicero probably made use in his own work on the same subject. In book ii. 42, Cicero quotes Panætius as 'one among the Stoics who rejected the predictions of the astrologers; and his disciple, Scylax of Halicarnassus, an astrologer himself, and also a distinguished statesman in his native town, as one who despised all the Chaldæan arts of fortune-telling.' Panætius wrote a treatise 'On Tranquillity of Mind,' which some suppose may have been made use of by Plutarch in his work bearing the same title. He wrote also a book 'On Providence,' mentioned by Cicero (*Ad Atticum*, xiii. 8), another 'On Magistrates,' and one 'On Heresies,' or sects of philosophers. His book 'On Socrates,' quoted by Diogenes Laertius, and by Plutarch in his 'Life of Aristides,' made probably a part of the last-mentioned work. Laertius and Seneca quote several opinions of Panætius concerning ethics and metaphysics, and also physics. He argued that the torrid zone was inhabited, contrary to the common opinion of his time. Seneca (*Epist.*, 116) relates his prudent and dignified reply to a young man who had asked his advice on the passion of love. For further information concerning this distinguished philosopher of antiquity, see 'Disputatio Historico-Critica de Panætio Rhodio,' by F. G. van Lynden, Leyden, 1802; and Chardon de la Rochette, 'Mélanges de Critique et de Philologie,' vol. i., Paris, 1812.

PANAMA', THE ISTHMUS OF, constitutes the most eastern and the narrowest portion of the long isthmus by which the two Americas are united. It extends, together with the province of Veragua, which is contiguous to it on the west, from 77° to 83° W. long., between 7° 20′ and 10° N. lat. When measured along its curve, the length from east to west is nearly 400 miles, but its width varies from 30 to 100 miles. It may cover a surface of about 30,000 square miles, or considerably more than the extent of Ireland.

The town of Santa Maria, the first European settlement in America, was founded by Balboa, in 1510, on this isthmus, but the site is now hardly known. Though the comparatively small width of the isthmus was soon discovered, and the great advantages which it offered to a speedy and easy communication between the Atlantic and the Pacific were apparent, yet for three hundred years after this discovery the natural features of this region were entirely unknown. Robertson, in his 'History of America,' observes that the isthmus is traversed in all its length by a range of high mountains; and it is only of late years that Mr. Lloyd, an Englishman, has surveyed the most eastern and narrowest part of it.

Surface, Soil, Climate, and Rivers.—The place where the Andes of South America terminate has not been quite ascertained. On our maps a mountain is laid down, near 8° N. lat., which is called the Peak of Candelaria, but it is not known whether it is connected with the Andes or is an isolated summit. There are some reasons for supposing that it is not connected with that mountain-range. But it is certain that west of this mountain (77° 30′ W. long.) no range of hills or mountains, not even an isolated elevation of moderate height occurs, and that the whole isthmus between the two seas is a flat country, only a few feet above high-water mark. This low country extends westward for more than a hundred miles to the western extremity of Mandingo Bay. The average width of this part of the isthmus does not exceed forty miles, and opposite Mandingo Bay, called also the Gulf of S. Blas, it contracts to less than thirty miles. The shores on both oceans are rocky, and the whole region appears to consist of an immense mass of rock. The rocks however are covered by a thick layer of vegetable mould, and are covered with high forest-trees. The shores of the Caribbean Sea are difficult of access for large vessels, being lined with numerous small rocky islands called *keys*. Two rivers drain the Isthmus. They are called respectfully Chucunaque and Chepo, and rise near 78° 20′ W. long. The Chucunaque runs east-south-east about eighty miles, and turning west by an abrupt bend falls into the Bay of S. Miguel; the Chepo or Ballano runs west-north-west, and empties itself into the Gulf of Panamá about 24 miles east of the town, making a similar turn to the south. Both rivers are navigable for large river barges as far as the places where the great bend occurs. With all the advantages which this region possesses from its great fertility and the vicinity of two great oceans and navigable rivers, it is thinly inhabited, and chiefly by a tribe of Indians, the Mandingoes or S. Blas Indians, who are at constant enmity with the white settlers, though they receive in a friendly manner the vessels which annually visit the country from Jamaica. The whites have only a few settlements on the Chepo river, and even these are chiefly occupied by negroes. The small town of Chepo, above the bend of the river of that name, is the most considerable settlement of the whites, but the inhabitants have little communication with their neighbours the Mandingoes. The scantiness of the population of this region is mainly if not entirely to be attributed to the unhealthiness of the climate. Being open on all sides to a vast expanse of ocean, every wind brings rain, and thus hardly a day passes in which the country is not drenched by heavy showers, which sometimes last for several days together. The surface of the country, not having sufficient slope to carry off such an abundance of moisture, is converted into an immense swamp. This moisture of the air indeed maintains a most luxuriant vegetation, but the great quantity of vegetable matter, which is annually reproduced and decomposed, increases the miasma which exhales from a swampy soil under the influence of a vertical sun.

At the western extremity of Mandingo Bay some hills commence, which gradually attain the elevation of mountains, and extend in a continuous chain as far west as a line drawn across the Isthmus from Port Limones to the town of Panamá, a distance of about 60 miles. These hills advance close to the shores of the Caribbean Sea, where they surround the town of Puerto Velo, but they remain a few miles distant from the Pacific, and are separated from it by a level prairie destitute of trees. These hills occupy nearly the whole width of the Isthmus, but they are divided longitudinally into two ridges, between which lies the valley of the river Chagres. The southern ridge does not exceed 1000 or 1100 feet in height, but the northern rises much higher, especially east of Puerto Velo. These hills are generally covered with thick and almost impenetrable forests. The valley of the river Chagres is rather narrow, but the river itself is navigable to a considerable extent. [CHAGRES.] The climate in this portion of the Isthmus differs considerably in the north and in the south. At Puerto Velo, on the northern coast, the rains are almost continual, and generally descend in torrents, a circumstance which renders that place very unhealthy. At Panamá, on the shores of the Pacific, the seasons are regular. In April the weather becomes cloudy about noon, but after drizzling for half an hour it clears up. In May, from nine to eleven o'clock, it is dull with slight rains, but the afternoon is fine. In June there is rain every morning and evening, but the middle of the day is fair. As the season advances, the rains gradually increase, and are incessant during July, August, September, and October. In November the nights are always rainy and cloudy, but during the days the sky begins to break. In December the weather improves, and in January, February, and March a shower of rain is as uncommon as a beam of sunshine in the other season of the year. The valley of the Chagres seems to partake rather of the climate of Panamá than of that of Puerto Velo. At Panamá the thermometer in the rainy season is 82° during the night and 87° during the day; but the winds being at that season variable and cool, there is no stagnation in the atmosphere, though the rain is incessant. In the dry season the temperature rises to 90° and even 93° in the day-time, and the days are very sultry, inasmuch as calms prevail at that season; but the land-winds at night are cool, coming chiefly from the adjacent mountains; and the climate may be called generally healthy, though a considerable mortality sometimes occurs.

West of a line drawn from the vicinity of Panamá to the

Bay of Limones begins the third region of the Isthmus, which extends westward on the Caribbean Sea to the rocky island called Escudo de Veragua, and on the Pacific to the innermost corner of the Gulf of Parita, a distance of about 80 miles. This country exhibits different natural features. It is, properly speaking, a plain which rises from both oceans with a very gentle ascent towards the middle of the Isthmus. Numerous isolated hills however, rising from 300 to 500 feet above their base, are dispersed over the surface of this plain. These hills occur much more frequently towards the extremities of the region near the mountains of Puerto Velo and the table-land of Veragua; in the middle of the region are plains of considerable extent, especially between the towns of Chagres and Chorrera; on these plains some isolated ridges of hills of inconsiderable height occur. The hills are generally covered with trees, but the plains and low grounds which surround them are savannahs or prairies, destitute of trees, but covered with grass, which supplies pasture to numerous herds of cattle and horses. Though the vegetation of this region is generally much less vigorous than in the country farther east, there are several cultivated tracts and others which may be cultivated. The climate also is much more healthy, especially on the slope towards the Pacific, which in climate and season exactly resembles the country surrounding the town of Panamá. The country along the shores of the Caribbean Sea is far less healthy, and the season much more irregular. Accordingly we find that the southern districts are comparatively thickly settled, while the northern are nearly uninhabited. The principal rivers of this region are the Trinidad and the Caymito or Chorrera. The Trinidad enters the Chagres about 24 miles from its mouth, after a course of about 60 miles. It rises near the south coast, not far from the town of Chorrera, and is navigable in the greatest part of its course as far up as the town of Capua. Traversing the Isthmus in a diagonal line from south-west to north-east, the agricultural produce of the more inhabited districts is conveyed by this river to Chagres. The Caymito or Chorrera is formed by several petty streams which descend from the eastern declivity of the table-land of Veragua, and though its course is short, it is navigable to the town of Chorrera. There is a harbour at its mouth, but the anchorage is bad and exposed.

West of this region is the table-land (mesa) of Veragua. Its eastern ascent is formed by projecting mountains of great elevation, rising abruptly, and frequently exhibiting an almost perpendicular face of bare rock. The surface of the table-land itself is very uneven, and several summits on it rise to a great height. The Peak de Veragua is stated to attain nearly 9000 feet above the sea-level. In some places however there are plains of considerable extent. The general elevation of this table-land above the sea-level is supposed to be between 3000 and 4000 feet. It approaches the Caribbean Sea within a few miles, and is separated from it by a narrow and slightly hilly tract. But on the side of the Pacific the mountains approach close to the sea, and between the Gulf of Parita and the Bay of Montijo project in a wide and mountainous peninsula into the Pacific. This peninsula terminates in the capes called Punta Mala and Punta Mariata. We are very little acquainted with the climate and soil of this region, but as it undoubtedly is much more populous than the lower part of the Isthmus, it must be presumed that it is favourable to agriculture and to the health of the inhabitants. This last circumstance is due to the great elevation of the surface above the sea-level. The rivers which descend from this table-land are interrupted by rapids and cataracts, and bring down great quantities of earthy matter, which they deposit at their mouths. All these rivers accordingly have a bar, with a very few feet of water on it, which renders them incapable of receiving vessels above 100 tons burden.

The most western portion of the Isthmus of Panamá begins at the western declivity of the table-land of Veragua, and extends to the boundary-line of Central America. This line begins on the shores of the Caribbean Sea at Chica or Monkey Point, and terminates on the Pacific at Punta Boruca. This region is rather more than 100 miles from east to west, and about 70 miles from north to south. The northern part is occupied by the Chiriqui Lagoon, a sheet of water 90 or 100 miles in length from east to west, and on an average twenty miles wide. It is separated from the Caribbean Sea by a series of low, swampy, and wooded islands, between which there are three deep passages for vessels. The most commodious of these passages is the most eastern, near a tongue of land projecting from the continent. It is called Chiriqui Mouth, and may be navigated by the largest vessels. Farther west is the entrance, called Boca del Toro (Bull's Mouth), which is only 18 feet deep, and narrow, but of easy access. The most western, called Boca del Dragon (Dragon's Mouth), is also narrow, but very deep. The middle portion of the lagoon is occupied by low woody islands, but at each extremity a considerable space is free from islands, and affords excellent anchorage, as the lagoon is deep, and the swell of the Caribbean Sea is broken by the intervening islands. The country contiguous to the southern shores of the lagoon, for a distance of about 20 miles, is low and swampy, the soil being covered with a thick layer of alluvium produced by the annual inundations during the rainy season. At the back of this low tract, which is generally wooded, the country rises, and though it contains plains of some extent, it continues to rise gradually for 40 or 50 miles from the lagoon, where it is bordered by a continuous ridge of high ground. This chain, which is called the Cabecares Mountains, may be between 4000 and 5000 feet above the sea-level, but it is of very inconsiderable width, being only about 500 yards across in its upper part, which extends in nearly a straight line without any peaked summits. The southern slope of this ridge is much more rapid, occupying only about 10 miles in width, and terminating on the Pacific in tolerably level tracts, which however are many feet above the level of the sea. The whole country north of the Cabecares Mountains is one continuous forest of lofty trees, but along the Pacific there are several woodless tracts. It is only in the last-mentioned district that the whites have formed a few establishments, the extensive country north of the Cabecares Mountains being in possession of the native tribes, especially the Valientes. This may be attributed to the climate, which on the coast of the Pacific resembles that of Panamá, being subject to regular changes of the seasons, and therefore healthy. But the low country about the Lagoon of Chiriqui is drenched with rain nearly all the year round: the more elevated tract however between it and the Cabecares Mountains has more regular weather, and is considered tolerably healthy. The numerous rivers which run from the northern slope of the mountains into the Chiriqui Lagoon are impeded by many rapids and cataracts until they reach the low country, where their course is gentle, and where they may be navigated by large boats; but they have bars across their mouths, with little water on them.

Productions.—This isthmus is very rich in vegetable productions. Lloyd has given a list of 96 trees, useful as timber, dye-woods, or for cabinet-work and domestic purposes. Some of them bear eatable fruits. It also produces all the fruits and esculent vegetables cultivated in other intertropical countries. The cultivated grains are rice and Indian corn. The sugar-cane is grown, but not extensively. Coffee and cacao are cultivated for domestic consumption; a small quantity of the latter is exported. The caoutchouc tree, milk tree (Palo de Vaca), sarsaparilla, and vanilla plant grow in the woods. The *Styrax officinalis* is very abundant, and its gum sells very dear. Cattle, horses, and mules are reared in those districts where there are natural prairies or savannahs. The woods are inhabited by numerous wild animals: tiger-cats, which seldom exceed the size of a small Newfoundland dog; lions, bears, racoons; sajinos, or a species of wild boars, which are frequently met in droves, and attack men; deer; conejos, which are somewhat like our rabbits, but larger; hosts of monkeys; wild turkeys, both black and coloured, and many other birds. The sea abounds with fish, especially sharks, which are eaten, alligators, and turtle. It does not appear that the snakes and poisonous reptiles for which the Isthmus was formerly noted exist in great number. There are gold-mines in the mountains near Puerto Velo, but their produce is insignificant. Gold is also said to be found on the northern declivity of the table-land of Veragua, and in the country of the Valientes. Copper and iron are abundant, and tin and mercury are stated to occur.

Political Divisions; Harbours; Towns.—The Isthmus constitutes one of the departments of the republic of New Granada, that of *Istmo*, and is divided into two provinces, the province of Panamá, which comprehends all the countries east of the table-land of Veragua, and the province of Veragua, which extends over the table-land of that name and the country south of the Chiriqui Lagoon, to the boundary-line of Central America. The province of Panamá is subdivided into six and that of Veragua into four cantons.

The coast along the Caribbean Sea, from the Bay of Candelaria, into which the river Atrato falls, to the Bay of Mandingo, does not present a single harbour for large vessels. It is lined by a continuous series of small keys, or rocky islands, lying from half a mile to a mile from the continent. The inner passage thus formed is full of coral rocks and reefs, but the water is so clear that they are easily seen and avoided in the day-time. Otherwise a vessel finds safe anchorage there, except during the prevalence of the north-western winds (from December to April), as the swell of the sea is broken by the islands. The first harbour which occurs on this coast is that of Puerto Bello, or Velo, which is about two miles long, and on an average 1000 yards wide. It is of considerable depth, and, being surrounded by high hills and mountains, affords excellent and safe anchorage for vessels. Though it once was a place of great trade, it is now rarely visited, on account of its excessive unhealthiness. The town, which is built on the southern shores of the harbour, consists of one long street with a few short streets branching off where the ground will admit of them. It is surrounded by mountains covered with dense forests: it contained, in 1827, not more than 1122 inhabitants, negroes and mulattoes. About 20 miles farther west is the Bay of Limones, or Puerto de Naos, which has an entrance five miles wide, free from danger. It is several miles deep, and several projecting points on its western side afford secure and commodious anchorage within them, especially the innermost, which is at present considered as the harbour. The climate is comparatively healthy, but it is not visited, the surrounding country being uninhabited. A few miles farther west is the harbour of Chagres, a little sandy bay, which is only open to westerly winds, and is formed by the mouth of the river of the same name. A ledge of rocks runs across its mouth, with not more than 15 feet of water in the deepest place, and in many rising even to the surface. Under the most favourable circumstances no vessel drawing more than twelve feet can enter the harbour. Farther westward there is no harbour, except those afforded by the Chiriqui Lagoon.

The harbours on the shores of the Pacific are all within the Gulf of Panamá. There appears to be no port west of Punta Mala. The opening of the Gulf of Panamá is between Punta Francisco Solano on the continent of South America and Punta Mala, where it is about 130 miles wide, which breadth it preserves for about 10 miles northward, when it begins to contract. In the northern and narrower portion of the bay there is a group of islands, called Archipelago de las Perlas, on account of the pearls which were formerly procured in the adjacent sea in great abundance, and still are taken in a considerable amount. The largest of these islands, called Isla del Rey, rises to a considerable elevation. Most of the rivers which fall into this bay admit vessels of considerable burden. They have indeed bars across their mouths, on which there is rarely more than three feet of water at low tides, but as the tides in this bay rise 18 feet, the bars may be passed at high-water, and inside of them the harbours are deep. The rivers which are sometimes visited by vessels are the river Pacora, about 18 miles east of the town of Panamá, and the Rio Grande, which enters the sea about two miles west of that town.

PANAMÁ is the principal trading-place on this bay. It stands on a tongue of land shaped nearly like a spear head, extending a considerable distance out to sea, and gradually swelling towards the middle. The principal streets extend across the peninsula from sea to sea. The houses are of stone, generally two or three stories high, substantially built, and the larger houses have courts or *patios*. The public edifices are, a beautiful cathedral, four convents, a nunnery of Santa Clara, and a *college*. As the sloping shore contiguous to the ground on which the town stands is dry at low-water to a considerable distance, the anchorage is about 6 or 7 miles distant, where it is protected by a number of islands, the largest of which is called Perico, a name which is also applied to the harbour. These islands are high and well cultivated, and supplies of ordinary kind, including excellent water, may be obtained from most of them. In 1827 the town had nearly 11,000 inhabitants. It carried on a considerable trade with several of the ports of South America, especially with Guayaquil.

In the interior of the Isthmus, west of Panamá, there are several considerable towns. The town of Chorrera, on the banks of the Caymito or Chorrera, has 4000 inhabitants. Natá has a population of 4259, and Los Santos of 4318. These two places are near the shores of the Bay of Panamá, but have no harbours. In the province of Veragua, the capital, Santiago de Veragua, had, in 1822, 4580 inhabitants; the town of La Mesa, 4421; and Santiago de Alanje, 2611.

Inhabitants and Population.—A great portion of the Isthmus, perhaps one-third, is still in the exclusive possession of the aborigines. These tribes occupy both extremities of the Isthmus. Nearly the whole of the Isthmus east of the Bay of Mandingo is inhabited by several small tribes, comprehended under the collective appellation of Mandingo or San Blas Indians. Roberts thinks that they are a race of people quite distinct from the other natives on the southern and western shores of the Caribbean Sea. He describes them as much shorter in stature, few of them exceeding five feet two or three inches in height, with a full chest and broad shoulders, and foreheads low and rather flat. Their eyes are small, and generally of a black or dark brown colour, their cheek-bones broad and full, and their lips not very thick. Among them he found some Albinos, who had been observed by earlier travellers. They are an active hardy race of people, very jealous of their independence, and hostile to the whites who have settled near them. The men do not go naked; the women are clothed in wrappers of blue baftas, or striped cotton, reaching from the breast to a little below the calf of the leg. They cultivate plantains, bananas, maize, and mandiocca, though the adjacent sea and the rivers abound in fish and turtle, and the forests in eatable animals. They also rear many fowls.

The western portion of the Isthmus, which surrounds the Chiriqui Lagoon, is inhabited by the Valientes, a collective name given by the Spaniards to different tribes inhabiting that part of the country. They are much taller than the Mandingo Indians, and seem to have made greater progress in civilization. Their dress formerly consisted of a covering made of a sort of tree-bark, six or seven feet long, and about five feet wide, with a hole cut in the centre to admit the head; but they have now partly adopted the European dress, and many of them put on a complete European suit. Their extensive plantain-grounds, maize-fields, and mandiocca plantations exhibit a great deal of industry and care; and among other things they plant the cacao-tree, the produce of which is extensively used.

The population of those parts of the Isthmus in which European settlements have been made consists chiefly of mulattoes and negroes, the number of whites being comparatively small, except in Panamá and in the larger towns. This however applies chiefly to the province of Panamá. According to a census taken in 1822, the department of Istmo contained a population of 101,550 individuals, viz.:—

Province of Panamá.		Province of Veragua.	
Canton of Darien ..	1,172	Canton of Santiago ..	14,170
" Puerto Velo	2,425	" Remedios	5,010
" Panamá ..	16,724	" La Mesa ..	8,722
" Chorrera ..	7,411	" Alange ..	7,465
" Natá ..	17,108		
" Los Santos	21,346		35,367
	66,186		

Commerce.—The countries inhabited by the Mandingo and Valientes Indians are annually visited by several vessels from Jamaica, which export considerable quantities of tortoiseshell, sarsaparilla, and fustic, and also some cacao; they import manufactured cotton goods, cutlass-blades, and a variety of toys and small articles. The port of Chagres is annually visited by from thirty to forty European vessels, which bring manufactured articles and wines, which are mostly paid for in bullion brought from the countries of South America bordering on the Pacific, to which parts the greater part of the cargoes are shipped at Panamá. The harbour of Panamá is usually visited by about thirty vessels, mostly from Guayaquil, Lambayeque, and Callao. They import sugar for the consumption of the country, and bullion and cacao for re-exportation. These goods are transported either on mules or by the natives on their shoulders from Panamá to Cruces, on the Chagres river, where they are embarked in boats, and go down the river to Chagres.

If a canal for large vessels could be made across any part of this Isthmus, not only the communication between Europe and the countries of America bordering on the Pacific would be much facilitated, but vessels bound for China and the countries of Eastern and Southern Asia would prefer a voyage which, besides being much shorter than that round the Cape of Good Hope, would have the advantage of a continual favourable wind (the trades). The execution of such a canal has repeatedly been suggested; and Mr. Lloyd was sent, in 1827, by Bolivar, then president of the republic of Colombia, to survey the country, with a view of improving the communication across the Isthmus. Mr. Lloyd, in what he has written on the subject, does not speak of a canal, probably because in the then circumstances of the republic of Colombia it was an enterprise quite out of the question. His description of the country however shows that it may be considered next to impossible to make such a canal across the narrowest part of the Isthmus, opposite the Bay of Mandingo. It appears that though there are no obstacles to the execution of such a work in the surface and soil which could not be overcome, the climate is so unhealthy, that the lives of many thousands would be sacrificed, and probably the mortality among the workmen would soon stop the progress of the work. If a canal for large vessels across the Isthmus is practicable, it can only be made west of the mountains which lie between Panamá and Puerto Velo, perhaps along the line which Mr. Lloyd proposes for improving the communication between the Caribbean Sea and Panamá. This line would begin at Limones, or Navy Bay, about five miles east of Chagres, which, though uninhabited, is an excellent harbour, and might easily be much improved. From this place he proposes a canal to be made to the banks of the river Chagres, which is only two miles and a half from the harbour; and as the intervening tract is a level, the canal could probably be made without locks. That river would then be ascended to its junction with the Trinidad river, and the latter to a place where its shores on the south bank are well suited for being converted into wharfs and landing-places, and thence finally to Panamá or Chorrera by a railroad. It may be supposed that if a more minute survey were made of this country with the view of making a canal across the whole isthmus, a straighter and shorter line might be discovered. Mr. Lloyd observes that the mean rise and fall of the tide in the Pacific two days after full moon is 21·22 feet; and that the difference between the extreme elevation and depression occasionally amounts to 27·44 feet. In the Caribbean Sea, at Chagres, the mean elevation of the tide is only 1·16 feet. The water at high-water mark in the Atlantic is 13·55 feet lower than in the Pacific.

History.—Columbus, in his fourth voyage, being in search of a strait which would conduct him to the Indian Ocean, discovered the whole coast between Cape Gracias à Dios and the harbour of Puerto Velo in 1502 and 1503. He intended to plant a small colony upon the river Belen in Veragua, but was prevented by the insubordination of his crew from making the first European settlement on the continent of America. This was done in 1510 by Nuñez de Balboa, who built the town of Santa Maria, on the Gulf of Darien; and in 1512, in traversing the Isthmus, he discovered the Pacific Ocean. As the climate along the coast of the Gulf of Darien is very unhealthy, Pedrarias Davila removed the colony from Santa Maria to Panamá; and the Spaniards, who were in quest of gold, soon spread over the Isthmus, and settled at several places. When the Spanish government divided its American possessions into large provinces, the Isthmus of Panamá was incorporated into the viceroyalty of Granada. The settlements on this Isthmus were frequently taken and plundered by the Buccaneers, especially by Henry Morgan. [BUCCANEERS.] In the beginning of the present century the Spanish colonies on the Tierra Firma obtained their independence after a long and bloody struggle, and the Isthmus of Panamá then formed first a department of the republic of Colombia, and afterwards of New Granada, under the name of Istmo.

(Lloyd, in the *Philosophical Transactions* for 1830, and the *London Geographical Journal*, vol. i.; Ulloa's *Voyage to South America;* Roberts's *Narrative of Voyages and Excursions on the East Coast and Interior of Central America;* Haigh's *Sketches of Buenos Ayres, Chili, and Peru.*)

PANATHENÆA (Παναθήναια), the greatest of the Athenian festivals, was celebrated in honour of Athena (Minerva) as the guardian deity of the city (Ἀθήνη πολιάς). It is said to have been instituted by Ericthonius, son of Hephæstus (Harpocrat., Παναθ.), and to have been called originally Athenæa (Ἀθήναια); but it obtained the name of Panathenæa in the time of Theseus, in consequence of his uniting into one state the different independent states into which Attica had been previously divided. (Paus., viii., 2, s. 1; Plut., *Thes.*, c. 20; Thucyd., ii. 15.)

There were two Athenian festivals, which had the name of Panathenæa; one of which was called the Great Panathenæa (μεγάλα Παναθήναια), which was celebrated once in every five years with very great magnificence, and attracted spectators from all parts of Greece; and the other, the Less Panathenæa (μικρά Παναθήναια), which was celebrated every year in the Piræus. (Harpocrat., *loc. cit.*; Plato, *De Rep.*, i. 1.) When the Greek writers speak simply of the festival of the Panathenæa, it is sometimes difficult to determine which of the two is alluded to; but when the Panathenæa is spoken of by itself, and there is nothing in the context to mark the contrary, the presumption is that the Great Panathenæa is meant; and it is thus spoken of by Herodotus (v. 56) and Demosthenes (*De Fals. Leg.*, p. 394).

The Great Panathenæa was celebrated on the 28th day of Hecatombæon (Proclus, quoted by Clinton, *Fast. Hell.*, p. 325), the first of the Athenian months, which agrees with the account of Demosthenes (*C. Timocr.*, p. 708, 709), who places it after the 12th day of the month. There is considerable dispute as to the time in which the Less Panathenæa was celebrated. Meursius places its celebration in Thargelion, the eleventh of the Athenian months; but Petitus and Corsini, in Hecatombæon. Mr. Clinton, who has examined the subject at considerable length (*Fast. Hell.*, p. 332-335), supports the opinion of Meursius; and it does not appear improbable that the Less Panathenæa was celebrated in the same month as the Great, and was perhaps omitted in the year in which the great festival occurred. The celebration of the Great Panathenæa only lasted one day in the time of Hipparchus (Thucyd., vi. 56); but it was continued in later times for several days.

At both of the Panathenæa there were gymnastic games (Pind., *Isthm.*, iv. 42; Pollux, viii. 93), among which the torch-race seems to have been very popular. In the time of Socrates there was introduced at the Less Panathenæa a torch-race on horseback. (Plato, *De Rep.*, i. 1.) At the Great Panathenæa there was also a musical contest, and a recitation of the Homeric poems by rhapsodists. (Lycurg., *C. Leocr.*, p. 209.) The victors in these contests were rewarded with vessels of sacred oil. (Pind., *Nem.*, x. 64, and Scholia; Schol. on *Soph. Oed. Col.*, 698.)

The most celebrated part however of the Great Panathenaic festival was the solemn procession (πομπή), in which the Peplus (Πέπλος) or sacred robe of Athena was carried through the Ceramicus and other principal parts of the city to the Parthenon, and suspended before the statue of the goddess within. This Peplus was covered with embroidery (ποικίλματα, Plato, *Euthyph.*, c. 6), on which was represented the Battle of the Gods and the Giants, especially the exploits of Zeus and Athena (Plato, *loc. cit.;* Eurip., *Hecub.*, 466), and also the achievements of the heroes in the Attic mythology, whence Aristophanes speaks of 'men worthy of this land and of the Peplus.' (*Equit.*, 564.) The embroidery was worked by young virgins of the noblest families in Athens (called ἐργαστῖναι), of whom two were superintendents, with the name of Arrephoræ. When the festival was celebrated, the Peplus was brought down from the Acropolis, where it had been worked, and was suspended like a sail upon a ship (Paus., xxix. 1, s. 1), which was then drawn through the principal parts of the city. The procession which accompanied it consisted of persons of all ages and both sexes, of foreigners resident at Athens as well as of citizens. The old men carried olive branches in their hands, whence they were called Thallophori (θαλλοφόροι), and the young men appeared with arms in their hands, at least in the time of Hipparchus. (Thucyd., vi. 56.) The young women carried baskets on their heads, whence they were called Canephori (κανηφόροι). The sacrifices were very numerous on this occasion. During the supremacy of Athens every subject state had to furnish an ox for the festival. (Schol. on Aristoph. *Nub.*, 385.) It was a season of general joy; even prisoners were accustomed to be liberated, that they might take part in the general rejoicing. (Schol. on Demosth. *Timocr.* 184.) After the battle of Marathon, it was usual for the herald at the Great Panathenæa to pray for the good of the Plataeans as well as of the Athenians. (Herod., vi. 111.)

The procession, which has been described above, formed the subject of the bas-reliefs which embellished the outside of the temple of the Parthenon, which are generally known by the name of the Panathenaic frieze. The blocks of marble of which this frieze was originally composed, were three feet four inches high, and they formed a connected series of 524 feet in length. A considerable portion of this frieze, which is one of the most splendid of the ancient works of art, is in the British Museum, and is described in the 'Elgin Marbles,' published by the Society for the Diffusion of Useful Knowledge, vol. i., p. 161-231.

A full and detailed account of this festival is given by Meursius, in a work on the subject, which is printed in the seventh volume of the 'Thesaurus' of Gronovius.

PANAY. [PHILIPPINE ISLANDS.]

PANCAKE, a thin cake of batter fried or baked in a pan. The annual custom of frying pancakes (in turning or tossing which in the pan there was usually a good deal of pleasantry in the kitchen) is still retained in many families of the better sort throughout the kingdom on Shrove Tuesday, and was formerly universal. The church bell which used to be rung on that day, to call the people together, in Roman Catholic times, for the purpose of confessing their sins, was called the pancake-bell, a name which it still retains in some places. At Newcastle-upon-Tyne, Brand says, the great bell of St. Nicholas church is tolled at twelve o'clock at noon on this day; shops are immediately shut up, offices closed, and all kind of business ceases, a little carnival ensuing for the remainder of the day. Macaulay, in his 'History and Antiquities of Claybrook in Leicestershire,' 8vo., London, 1791, p. 128, says, 'On Shrove Tuesday a bell rings at noon, which is meant as a signal for the people to begin frying their pancakes.'

According to Brand (*Popular Antiq.*, vol. i., p. 75), a kind of pancake feast preceding Lent was used in the Greek church, from whence we may probably have borrowed it, with pasche eggs and other such ceremonies. The Russes, Hakluyt says, begin their Lent always eight weeks before Easter. The first week they eat eggs, milk, cheese, and butter, and make great cheer with pancakes and such other things. [SHROVETIDE.]

PA'NCHA-TANTRA, a celebrated collection of fables in the Sanscrit language. It owes its name to its division into five *Tantras*, or chapters, which are headed—1, *mitra bhéda* (*dissension of friends*); 2, *mitra prápti* (acquisition of friends); 3, *kákolúkíya* (inveterate enmity; lit., 'the war of the crow (*káka*) and the owl (*ulúka*);' 4, *labdha pranásana* (loss of advantage); 5, *aparíkshita káritwa* (inconsiderateness). It is also more commonly known in India under the name *Pánchópákhyána* (*pancha-upákhyána*), 'the five (collections of) stories.' The author is reputed to have been Vishnu-Sarmá, and the collection was probably first published in the sixth century A.D., for it quotes Varahamihira, who did not write till A.D. 540, and it was carried from India to Persia in the reign of Nushirvan, king of Persia, who died A.D. 579.

Barzuyeh, the physician of this prince, who was the importer of the *Pancha-tantra*, got it translated into old Persian, under the title of *The Fables of Bidpai* (in Sanscrit, *Vidyá-priya*, 'the friend to science,' or 'the physician'). In the year 760 A.D., or thereabouts, it was translated into Arabic by Abdallah Ebn Mokaffa, under the title *Kalila wa Dimnah*, from *Karataka* and *Damanaka*, the Sanscrit names of the two jackals who are the chief interlocutors in the first *Tantra*, in the same way as *Sanjívaka*, the name of the ox who falls and is left behind, is transformed into *Shanzebah* in the Arabic version. From this Arabic version, from a Greek translation of it by Simeon Sethi, about the year 1080, and from a Latin translation by John of Capua, in the thirteenth century, this collection of fables was translated to all the languages of Europe, and most of the stories of which it is composed are familiar to persons conversant with modern literature; for instance, the story of the faithful dog killed by the hasty parent, after having successfully guarded the life of her child, which appears in most European collections of fables, and also forms the subject of a ballad ('Beth Gelert'), is derived from the story of the Brahman and the ichneumon in the fifth book of the *Pancha-tantra*; and an incident from the story of Déva-Sarmá, in the first book, appears among other works in the *Cheveux coupés* of Guérin, in Massinger's 'Guardian,' and in Beaumont and Fletcher's 'Women pleased.' The original text of the *Pancha-tantra* has not yet been printed, but there is a Sanscrit epitome of it, known by the name *Hitópadésa* (the friendly instruction), which is in the hands of all Sanscrit scholars, and has been translated both by Sir C. Wilkins and by Sir W. Jones. It seems that the *Pancha-tantra* was composed at or near the city of Mihilapur, or St. Thomé, which is called Mihilárópyam, in the introduction to the book.

In the 'Transactions of the Royal Asiatic Society,' vol. i., p. 155, there is an admirable 'Analytical Account of the *Pancha-tantra*, illustrated with occasional translations,' by Professor Wilson.

PANCRA'TIUM, a genus of plants of the natural family of Amaryllideæ, having a funnel-shaped flower with a long tube. Six superior sepals, and as many stamens, which are inserted on the edge of a 12-cleft membranous cup. Pistil single. The name was applied by the Greeks to some plant allied to *Scilla maritima*, but which has not yet been made out by botanists. The name is now applied to a genus of ornamental plants, found in the equinoctial parts both of the old and of the new world, and of which one species extends to the coasts of the Mediterranean. They are mostly highly ornamental plants with white flowers, many of them fragrant; they are commonly cultivated in stoves, and require a mixture of light loam and rich vegetable mould, with little water when not in a growing state.

PA'NCREAS is a secreting gland situated behind the stomach and extending from the spleen transversely across the vertebral column to the duodenum. In man it is of an elongated and slightly flattened form, broadest at its right extremity, and gradually diminishing in breadth towards the left. It is of a firm consistence, lobulated, and very similar in structure to the salivary glands, from which circumstance it is often called the salivary gland of the abdomen. It is chiefly composed of the ramifications of the main duct, through which its secretion is poured into the bile-duct, or into the duodenum by a separate aperture close to that of the bile-duct. [LIVER.] The trunk of the pancreatic duct, soon after its opening into the end of the bile-duct, or into the duodenum, dilates and passes along the middle of the gland, giving off on each side numerous branches, which, again and again dividing, terminate in minute cells or lobules, which are closed on all sides, and are congregated in bunches to form the principal lobes of the glands.

Upon the walls of these ducts and their vesicular terminations the blood-vessels of the pancreas ramify and form a close capillary net-work, through whose walls the peculiar secretion is poured. This is a ropy, slightly acid, and opaline fluid, very similar to saliva, containing a small quantity of albumen and some other animal matters in solution. It is presumed to assist in the office of assimilating the food, which, just before the pancreatic fluid is added, has been converted into chyme in the stomach, and is undergoing the process of conversion into chyle; but the exact nature of its function is at present unknown. [DIGESTION.]

The pancreas is found in its least developed form in fish, in some of which it consists of simple or slightly branching tubes or sacs, attached to the duodenum very near its commencement, and commonly called appendices pyloricæ. In the amphibia and birds it gradually increases in the complexity of its arrangement, and it is most compact and most highly developed in the mammalia.

Of all the organs in the body, the pancreas is probably the least liable to disease, and those from which it is occasionally found to have suffered are not indicated during life by any peculiar symptoms.

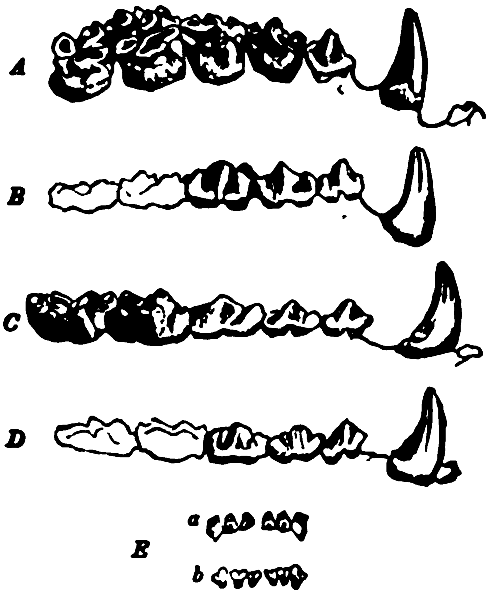
PANDA, one of the names of the genus *Ailurus* (F. Cuv.).

On the 6th November, 1821, an elaborate description of this interesting animal by General Hardwicke was read to the Linnean Society of London. The publication was delayed till the author's return to England, when he brought with him a second skull of the same species from India. Whilst the paper was going through the press, he found that a description and figure had been recently published by M. F. Cuvier in his *Histoire des Mammifères*, under the name of *Ailurus fulgens*, and the General's name was therefore, with his consent, suppressed.

The French attribute the discovery of the animal to M. Duvaucel.

Generic Character.—*Head* subglobose, great; *face* subrotund; *cheeks* tumid; *forehead* flat, elongated, broad; *tongue* rather rough; *snout* short, conical, very broad; *rictus* moderate; *rhinarium* obtuse; *nostrils* terminal; *ears* short, acute, distant, villous; *eyes* approximated to the *rhinarium* and placed anteriorly; *maxilla* intumescent; *mandible* subrecondite; a few white *vibrissæ*. *Neck* short. *Body* large, cylindrical, obese, clothed with a very villous under-fur, and long, equal, rather soft hairs, downy at their base. *Tail* of the length of the body, very large at the base, cylindrical, subattenuated at the tip and clothed with very long spreading hair. *Feet* plantigrade, five-toed; the *soles* thickly clothed with a very fine down; *claws* falculate, compressed, arcuate, very sharp (retractile).

Dental formula:—Incisors, $\frac{6}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{5-5} = 36$.



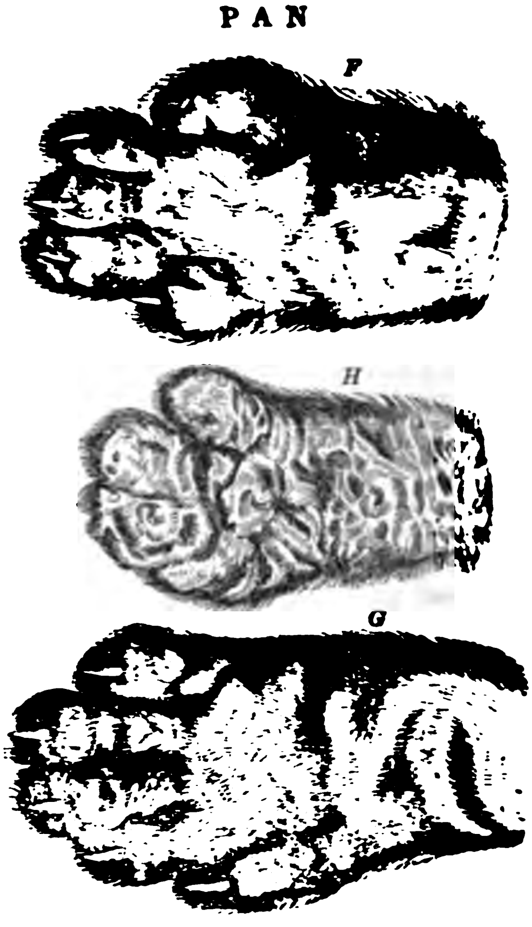
Teeth of Ailurus.

A, lateral view of the teeth of the upper jaw, as they are seen within. *B*, the same as they are seen without. *C*, lateral view of the teeth in the lower jaw, as they appear within. *D*, the same as they appear without. *E*, front teeth; *a*, upper jaw; *b*, lower jaw. (Hardwicke, *Linn. Trans.*)

Example, *Ailurus fulgens*. (F. Cuvier.)

Description.—Body above beautiful fulvous brown, which becomes lighter on the back and assumes a golden hue. The brown colour extends with a somewhat deeper shade to the neck, the sides of the head, and the ears posteriorly; a band of the same colour arises from the ears, and unites to the back of the neck. The face, snout, and ears white; a few fulvous and yellowish hairs are mixed with the white covering of the forehead. The abdomen and extremities black, and separated by a defined line from the colour of the upper parts. The tail is banded alternately fulvous brown and yellow, and tipped with black. The woolly covering of the soles of the feet of a black or greyish colour. Length of the head 7½ inches; from the occiput to the root of the tail 19½ inches; length of the tail 15 inches: total 3 feet 6 inches. (Hardwicke.)

'The peculiarities of our animal,' says the General in continuation, 'on which its rank as a genus depends, are striking and prominent; but its disposition in a natural series is still obscure, as it resembles in several characters the individuals of that subdivision of digitigrade carnassiers, from which it differs essentially both in its teeth and in its plantigrade walk. Among the peculiarities of our animal are to be noticed the great breadth of the rostrum and the singular structure of the teeth: but the most remarkable character, and that on which its distinction principally depends, is the form of the projecting points of the posterior grinders. This character, as far as our observation extends, is peculiar; it does not exist, except in a small degree, in any other genus of carnivorous quadrupeds. The truncation is owing, in our opinion, to original structure, and is not produced by the wearing down of the points. We observe it both in the skull of a young animal and in that of the adult specimen from which the annexed drawing was made; and our description is confirmed by a careful comparison of the relative elevation of the points of the two anterior grinders, in which, although they are equally exposed to attrition, this truncation is not observed. The margins bounding the truncated points, as is shown in the drawing, are circumscribed and perfect, exhibiting no signs of being worn down by attrition. In the disposition and even in the form of the teeth, our animal bears some resemblance to the genera *Nasua* and *Procyon*; but these differ essentially in the lengthened form of the head, and in the extended rostrum, which is terminated by a flexible rhinarium; they also differ in the number, character, and distribution of the grinders. *Nasua* and *Procyon* have in both jaws six grinders, of which the three anterior are false grinders; and of those which follow, none of the points, even in the adult state, exhibit the truncation above described. Our animal has only one false grinder with a compound crown, and the four posterior grinders are large and highly complicated: the first of these in the upper jaw corresponds with the fourth grinders in *Nasua* and *Procyon*, and the points are attenuated and acute; but the posterior grinders are quite peculiar and characteristic in their structure.'



Feet of Ailurus.

F, anterior foot, left side. *G*, posterior foot, right side. *H*, sole of one of the posterior feet, to show its hairy covering. (Hardwicke, *Linn. Trans.*)

Habits, &c.—General Hardwicke states that this animal's haunts are about rivers and mountain-torrents. It lives much in trees, and feeds on birds and the smaller quadrupeds, and is frequently discovered by its loud cry or [illegible], resembling the word *Wha*, often repeating the same. Hence is derived one of the local names by which it is known. It is also called the *Chitwa*.

Locality.—Himalaya chain of hills between Nepaul and the Snowy Mountains (Hardwicke, *Linn. Trans.*, vol. xv.). In Mr. Hodgson's catalogue of the animals observed in Nepaul (*Zool. Proc.*, 1834).

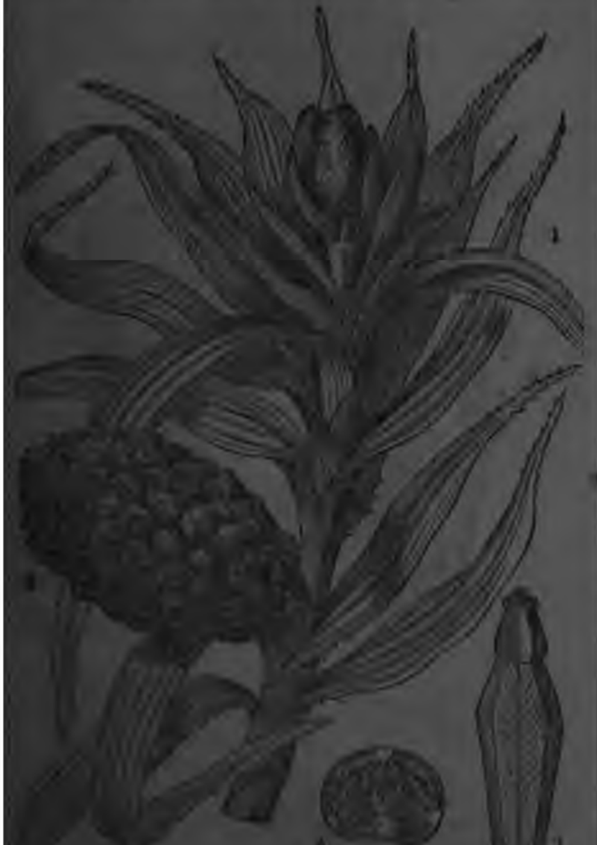
Cuvier declares the *Ailurus* to be one of the most beautiful of quadrupeds.

Ailurus fulgens. (F. Cuvier.)

Place in the System.—Cuvier places *Ailurus* among the Bears, between *Procyon* (Racoon) and the Benturongs (*Arctictis*). J. E. Gray arranges it between *Gulo* (Glutton) and *Arctictis* (F. Cuv., *Paradoxurus* and *Ictides* of F. Cuv. and Valenciennes). M. Lesson follows Cuvier. Mr. Swainson ('Classification of Quadrupeds') says of it, 'Whether this animal leads to the Racoons, or whether these latter belong to the Bears, are questions which need not here be discussed; Cuvier has placed them together, and we may for the present follow his example.' In the arrangement (Part iii. of this vol.) the form appears to be altogether omitted.

PANDANA'CEÆ are arborescent or bushy plants, with long, rigid, sword-shaped leaves, resembling those of the pine-apple, usually arranged in a manner so obviously spiral that they are commonly called *screw-pines*. In a natural arrangement they are classed with Endogens, among which they are, more especially in the genus Pandanus, remarkable for their stems forking repeatedly. Their flowers have the sexes separate, and quite covering the spadix on which they grow. The male flowers consist of single stamens with two-celled anthers; the females of naked one-celled ovaries, with solitary ascending or numerous parietal ovules. The fruit consists of a mass of ovaries collected into a tuberculated head, and either dry and fibrous or fleshy and succulent.

These plants chiefly abound in the Mascaren islands and in the Indian Archipelago, of which they form a conspicuous feature. The species of Pandanus, Vaquois, or Screw-pines, are readily known by their spiral leaves, dichotomous habit, and the long roots emitted by the sides of their trunk for the purpose of holding it down in the loose sand among which they grow; in order to assist in which each root is furnished with a partial exfoliation of the end, which, in the form of a cup, adheres to the root, for the purpose, as is supposed, of holding water during the period that the root is passing through the dry air. The genus Freycinetia, on the contrary, is composed of plants with long scrambling or rooting stems, not branching like Pandanus, indeed seldom becoming what can be called a tree, and, when in flower, adorned with gaily coloured spathes from which the young inflorescence protrudes. It can scarcely be said that the plants of this order are of any known use to man, except as furnishing, in common with many others, a good material for thatching.



Pandanus odoratissimus.

1, Male panicle; 2, [illegible]; 3, an ovary; 4, a transverse section of the ovary, showing the parietal placentation.

PA'NDANUS, a name derived from the Malay *Pandang*, and that of a genus of plants, from which the natural family of Pandanaceæ, or Screw-Pine tribe, has derived its name, being so named from their leaves, which resemble those of the pine-apple, and are inserted spirally along the stem. The species are found in the islands of the tropical ocean, in those of Mauritius and Bourbon, as well as in the southern parts of India. One species, *P. odoratissimus*, being highly fragrant, is much esteemed in all Asiatic countries, either where it will grow or where its essence is known. It is constantly referred to by the Sanscrit poets, as may be seen in Wilson's 'Hindu Theatre,' by the name *Ketaka*, and as the *Keora* and *Ketgee* of the Hindus. The Arabs call it *Kazee*, and Avicenna describes it under the name of *Armak*. Oil impregnated with the odour of its flowers and the distilled water are highly esteemed both for their odour and their medicinal use as stimulants. Dr. Roxburgh states that it is the tender white leaves of the flowers, chiefly those of the male, which yield the very delightful fragrance for which this plant is so celebrated. This species is common in the peninsula of India, where it is called Caldera Bush; in Mauritius it, as well as other species, is known as the Vaquois Plant; in Otaheite, a species is called the Wharra Tree, being in all highly esteemed for its odour, as well as for the useful purposes to which it may be applied. The lower pulpy part of the drupes is sometimes eaten, as is also the terminal bud, like that of the cabbage-palm, and likewise the tender white base of the leaves, either raw or boiled, during times of scarcity. It forms an excellent hedge, but occupies too much space. The roots are composed of tough fibres, which are used by basket-makers to tie their work, and are soft enough to be employed as corks. The leaves are composed of tough longitudinal fibres, white and glossy, a quality which adapts them for covering huts, making matting, as well as for cordage in the South Sea islands, and in the Mauritius for making sacks for their coffee, sugar, and grain.

PANDECT. [JUSTINIAN'S LEGISLATION.]

PANDI'ON. [BALD BUZZARD.]

PANDO'RA (Malacology). [PYLORIDEANS.]

PANDUS. [MAHABHARATAM.]

PANEGYRIC (from the Greek 'panegyricus,' πανηγυρικὸς λόγος) is a species of oration in praise of a person or thing, so called because such discourses used to be delivered in ancient Greece on the occasion of great public festivals before the whole assembly, 'panégyris,' of the people. The orator began by praising the deity who presided over the festival, such as Jupiter in the Olympic Games and Apollo in the Pythian; he then spoke in praise of the community or town in which the games were held, and lastly of the magistrates, the champions, and especially the victors who gained the prizes. Afterwards the name came to be applied to political orations delivered in the senate or council of a state in praise of that state or of the leading men or man in it. The panegyrical oration of Isocrates is a fine specimen of the kind, in which he commemorates the glories of Athens, the services which it had rendered to Greece in general, and the whole with a view to nourish friendly feelings between it and the other Greek states, The Panathenaic oration of Isocrates is another composition of the same class.

Under the Roman empire panegyrics were composed in praise of the emperors. Pliny's panegyric of Trajan is a well known specimen of this kind. Panegyrics became frequent under the late emperors, both of the East and the West, in Greek and in Latin; they are mostly however written in a fulsome and adulatory style. We have panegyrics of Constantine, Constantius, Justinian, Theodosius, and others, which, if consulted with discrimination, may be useful for historical purposes and for supplying deficiencies in the historians of those times. Eunodius, bishop of Pavia, wrote a panegyric in praise of Theodoric.

Panegyrics have also been written in verse. The poem of Tibullus in praise of Messala is a specimen of this kind, as well as similar compositions by Claudianus, Sidonius, and others.

In modern times panegyrics have been written by Roman Catholic preachers in honour of particular saints. Giordani, an Italian contemporary author, wrote a panegyric in praise of Napoleon, in imitation of that of Pliny. But the panegyrical style seems no longer in accordance with the taste of our age, and its essential character is too laudatory to please minds of an independent cast.

PANEL. This term in English law denotes a small schedule of paper or parchment containing the names of jurors returned by the sheriff or other ministerial officer for the trial of issues in courts of common law. The enrollment of the names upon this schedule is called *impanelling* a jury; the ministerial officer is also said to *array* the names in the panel. The etymology of the term is doubtful: Sir Edward Coke says, 'Panel is an English word, and signifieth a little part, for a *pane* is a part, and a panel is a little part' (Co. Litt., 158 b). Spelman derives the word from *pagella*, a little page, supposing the *g* to be changed to *n*. (Spelman's *Gloss.*, tit. 'Panella'). Both these etymologies seem to be incorrect. In the old book called 'Les Termes de la Ley,' *panel* is said to come from the French word *panne*, a skin; whence in barbarous Latin might come *panellus* or *panella*, signifying a little skin of parchment. This would denote the jury panel pretty accurately, and the history of its appearance as an expression in English procedure is consistent with its derivation from the French.

In the earliest records of the forms of jury-process, as given by Glanville, it appears that the sheriff was commanded by the writs in certain real actions to cause to be imbreviated (imbreviari facere) the names of the jurors by whom the land in question was viewed. But at this time the word *panel* never occurs, nor is it used by Bracton, Fleta, or Britton, nor in any statute earlier than 20 Edw. III c. 6 (1349), which forbids sheriffs from putting suspected persons in *arrays of panels*. This was precisely the period at which the French language began to be fully introduced into our law proceedings. (Luders's 'Tract on the Use of the French Language in our Antient Laws.') This coincidence renders it not improbable that the word *panel*, from *panelle* and *panne*, may have been introduced with many other French terms about this period.

In Scotch criminal law, the accused, who is called a defender till his appearance to answer a charge, is afterwards styled the *pannel*. The etymology of this word also is doubtful. (Jameson's *Dictionary*, ad verb.) But it is possible that it may have the same origin as our English word, as in Scotch proceedings a prisoner is sometimes said to be *entered in pannel* to stand trial. (Arnot's *Criminal Trials*, p. 12.)

PANGOLINS, a name in common use to designate the *Scaly Ant-eaters*, said to be derived from the word *Pangoeling*, which signifies in the Javanese language, according to Seba, an animal which rolls itself into the form of a ball. The Bengalese name is *Badjarkita*, or *Reptile of stone*. These animals form the genus *Manis* of Linnæus.

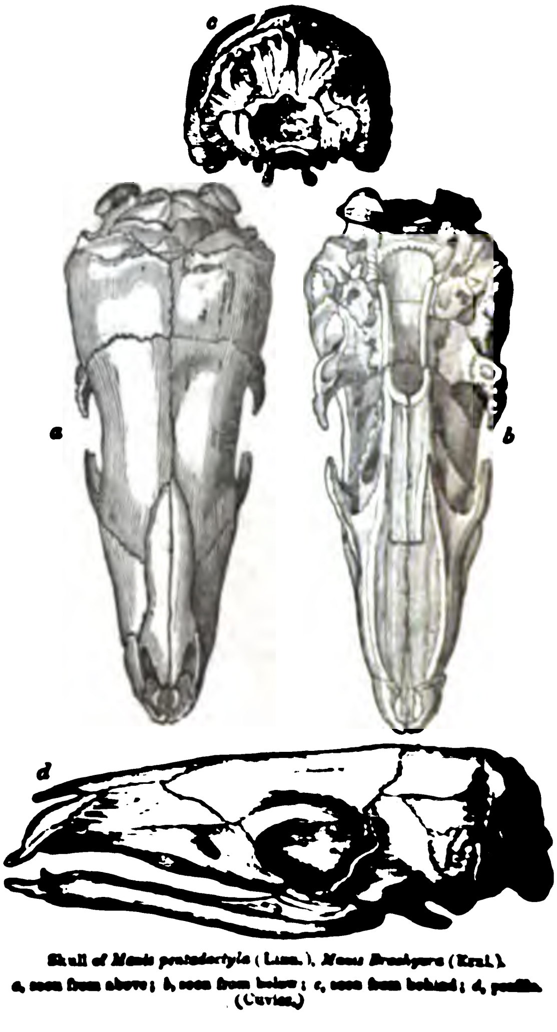
Like the *Hairy Ant eaters* (*Myrmecophaga*) [ANT-EATER; TAMANDUA], the *Pangolins* are toothless, and furnished with a very extensible tongue; but their tegumentary covering is very different, for their body, limbs, and tail are clad in a panoply consisting of great trenchant scales overlapping each other like tiles, so as to form a sort of scale-armour when the animal is on its feet. When it is vigorously attacked, and often on the first approach of danger, it rolls itself up in the shape of a ball; and then the trenchant scales are erected, and offer their sharp edges to the enemy.

Geographical Distribution.—The antient continent, &c only. Asia and Africa.

We must first call the reader's attention to those parts of the organization of this form which are most worthy of notice.

ORGANIZATION.

Skeleton.—*Skull*, a more or less elongated cone, with the base rounded. Orbits small, round, occupying nearly one-half of its length, and situated towards the lower parts of its sides: they are consequently very much separated from each other. The zygomatic arches are incomplete, and nearly on a level with the palate. The bones of the nose are notched on their inferior border, and enter above into a notch formed in the frontal bones. The articulation of these with the maxillary bones descends obliquely to the orbit, and is continued in the same direction with the palatine bone. The maxillary bone does not enter into the orbit; it terminates at the point where it gives off its zygomatic apophysis, which is short and pointed. The palatine bone itself furnishes, a little, the base of this apophysis. There is no lachrymal bone, or, if there is one, it is extremely small, and hidden in the lachrymal hole, and pierced in the angle of the orbit within, between the frontal and palatine bones. The fronto-parietal suture is hardly angular backwards, but the occipital suture forms a fairly defined angle between the posterior borders of the parietal bones. Cuvier could not detect any interparietal bone. The anterior sphenoid bone in the temple is far from reaching the parietal bone. The frontal bone is articulated with that and the temporal bone. The posterior sphenoid bone does not reach the frontal, but terminates opposite the origin of the zygomatic process of the temporal bone. In this place it contributes to the glenoid facet, which is sunk in front of the tympanic cavity. There is no jugal bone, and the temporal and maxillary zygomatic apophyses are only joined by a ligament. The tympanic cavity must be ossified at a late period only, for Cuvier never saw it except under the form of a vesicular



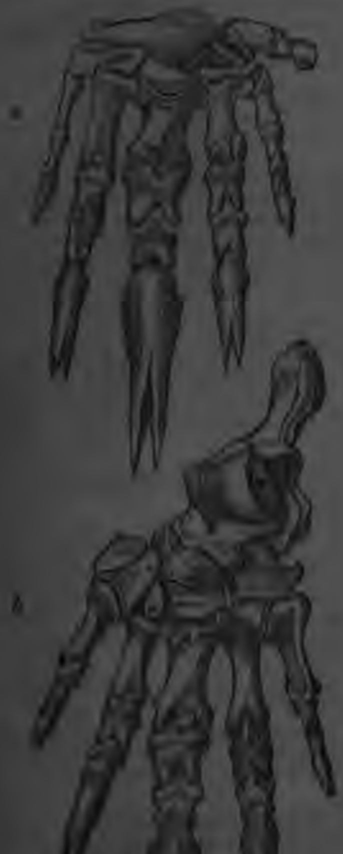
Skull of *Manis pentadactyla* (Linn.), *Manis Brachyura* (Erxl.)
a, seen from above; b, seen from below; c, seen from behind; d, profile.
(Cuvier.)

this. There is indeed a large petrous bone behind it, but only at the lower surface of the skull. Above this part the temporal bone is tumid, and contains a large cellule which communicates with the tympanic cavity by means of a hole pierced above the meatus. The intermaxillary bones are rather narrow, and rise obliquely in the half of the length of the nasal bones. Though there are no teeth the maxillary and palatine bones are raised along their sides, so that the middle of the palate forms a long channel. The palatine bones terminate obliquely opposite to the glenoid facet, and are continued from it by the pterygoid process of the sphenoidal bone, terminating in a hook within the internal side of the tympanic cavity. There is no external pterygoid apophysis; the internal one is not separated from the sphenoid bone. The suborbital hole is small, and its very short canal opens under the origin of the zygomatic arch. The lachrymal hole in the internal angle of the orbit is also large. There are in the palatine bone two holes corresponding to the spheno-palatine foramina. The anterior orbital hole is situated between the frontal and the anterior sphenoidal bone. The optic hole is moderate. The spheno-orbital is round and large. The oval is distinct, and entirely in the sphenoid. The condyloidean hole is large, but the posterior and carotid groove are small.

Internally the sella turcica is moderately elevated; the cribriform plate is very large, and divided by a very large and very bony crista-galli-like crest, separated also from the rest of the cranium by a projecting bony ring.

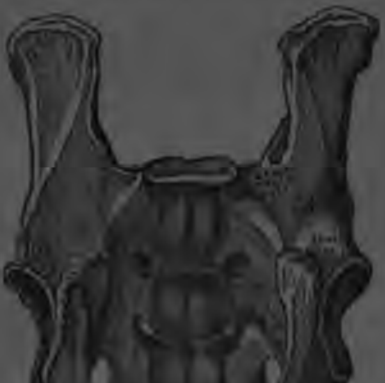
The skull of *Manis tetradactyla* (Linn.), *Manis Macroura* (Desm.), the *Phatagin* of Buffon, differs from that above described in being more slender, and also presents the singularity of having, where the lachrymal bone should be, a great oval space without any hole, which, Cuvier believes, belongs to the ethmoid bone.

Extremities.—There is a general resemblance in these portions of the skeleton in the *Hairy Ant-eaters* and the *Pangolins*; but there are particular differences, as in the scapula, &c., some of which we shall notice. Both of these groups are remarkable for the great size of the lower part of the humerus, produced especially by the projection of the internal condyle destined for the attachment for the powerful flexors which work the claws. In the *Hairy Ant-eaters* the head of the radius is nearly as round as it is in man and the Quadrumanes, having a very complete rotatory power; but it is not so in the Pangolins, which have the articulation of this part by the method termed ginglymus. The ulna and radius are both robust, and are constructed with proportions and views very different from those to be observed in the Sloths, among which they are so greatly prolonged as to be hardly fit for anything but suspension from trees. [Ai, vol. i., p. 231.] In the *Ant-eaters* they have all the strength necessary for tearing down the nests of the *Termites*, on which they feed; and, as it might be expected, the fore-feet of these quadrupeds is, next to their skull, the most remarkable part of their skeleton. The ungual phalanges of their large toes are, like those of the Sloths, so disposed as not to be capable of curvature in any other direction than downwards; and are in effect held in that position, the state of repose, by strong ligaments. In the *Pangolins* their point is forked, whilst in the *Hairy Ant-eaters* it is only furrowed, and has at its base a strong bony sheath for the insertion of the claw. In the *Pangolins* the general structure of the fore-foot is the same as in the *Hairy Ant-eaters*; but besides the differences above noticed, the scaphoid and semilunar bones of the carpus are confluent, forming a single piece, as in the Carnivora. In the Pangolins there is, too, less irregularity in the proportions of the toes, though in them, as well as in the *Hairy Ant-eaters*, the middle one is stoutest and longest.



a, Fore-foot of Pangolin; b, hind foot of the same. (Cuvier.)

The *pelvis* in all these animals exhibits the singularity of the ischium uniting with the last vertebra of the sacrum, which is furnished with apophyses for its reception, so that instead of the ischiatic notch there is a hole, which at first sight has the semblance of a second oval hole, a conformation observable in the Sloths and Armadilloes. In the *Pangolins* the os ilii, which is of a prismatic form, and terminates in front by a tuberosity, is articulated also to the last lumbar vertebra; but this is not the case among the *Hairy Ant-eaters*, where this bone is besides flatter; in both it is oblong, and not widened as in the Sloth.



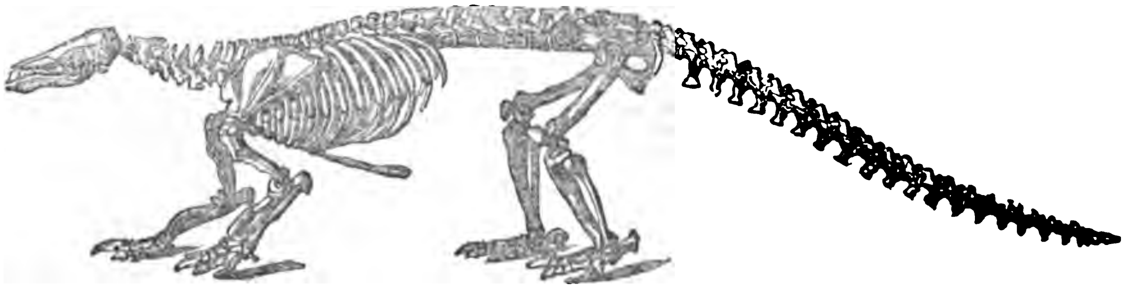
Pelvis of Pangolin. (Cuvier.)

The great trochanter is less elevated than the head of the femur; in the *Hairy Ant-eaters* there is a trenchant crest the whole length of the external edge of the bone; and in the *Pangolins* the whole bone is wide and flat from before backwards, but there is no third trochanter. The lower head of the bone is as wide as it is long, and the rotular pulley is wide but not deep. The tibia and fibula are very distinct; the former is very complete towards the lower part; the latter is rounded in front; its lower head is wider than it is long, and becomes a convex pulley (not projecting much) in its middle part. The astragalus forms sponds to this in the form of its upper head, the lower only corresponds to the scaphoïd bone, and is concave, as it is in the Sloths, which is remarkable; but the articulation of the astragalus with the tibia has none of that singular obliquity observable in those animals. The hind-foot of the *Hairy Ant-eaters* and the *Pangolins* is as solid as that of any animal. The calcaneum is compressed at its posterior apophysis, and is united to the astragalus as in most animals. In the tarsus there is a scaphoïd bone, which is convex on the anterior side of its articulation with the astragalus, but curving behind that bone; a cuboïd longer than it is wide; three cuneiform bones, the internal of which is double that of the others; and a supernumerary bone articulated on this internal cuneiform bone, and which in the *Tamanoir*, *Tamandua*, and the *Pangolins* is triangular and very small, but in the *Little Ant-eater* is elongated and widened so as to form a sort of heel. This species of calcaneum, it is true, is very short, not going farther backwards than the astragalus itself. It is this supernumerary bone which gives to the sole of the foot of the *Little Ant-eater* that concave form which renders it so fit for grasping branches and climbing trees.

Bones of the Trunk.—The Pangolins are remarkable for the strength of their caudal vertebræ, and for the extended width of their transverse apophyses: there are forty-seven in the tail of *Manis macroura*, and only twenty-six in that of the *Short-tailed Pangolin*, which has three sacral, six lumbar, fifteen dorsal, and seven cervical vertebræ: in the *Phatagin* Cuvier found only thirteen dorsal and five lumbar vertebræ. The spiny apophyses of the back and loins of these two animals are square, as in the *Tamanoir*.

The ribs of the *Tamanoir* and the *Ant-eater* (Fourmilier) are remarkable for their size; those of the latter often cover each other like the portions of certain cuirasses. There are sixteen in the *Tamanoirs*, ten of which are true, seventeen in the *Tamandua*, eleven of which are true; and fifteen in the *Ant-eater* (Fourmilier), nine of which are true. This last is also the number in the Pangolin, which has besides a slight vestige of a sixteenth, but in the *Phatagin* Cuvier found but thirteen. The sternum of the *Tamanoir* and *Tamandua* is very remarkable on account of a double body, which each of the bones possesses, a cylindrical part within the breast, and an external compressed part. The cartilages of the ribs, which are ossified, have at their sternal extremity two heads separated by a notch, and which articulate with these two parts, and always between two sternal bones. Each of these last leaves between it and its neighbour in the skeleton a vacant space, which traverses the sternum from right to left. The first of these sternal bones is very much widened and notched in front; the last is nearly rectangular. In the *Little Ant-eater* this last is cylindrical.

The Pangolins have the bones flat, eight in number, of which the three penultimate are placed transversely, and the last of all, which is very long, cylindrical, and forked in the *Pangolin* (flattened in the *Short-tailed Pangolin*), terminates in two strong tendons, which, in the latter, reach to the pelvis, and greatly assist the animals in rolling themselves into a ball.



Skeleton of Short-tailed Pangolin. (Cuvier.)

Generic Character.—Lower jaw very small; tongue very extensible. Body and tail entirely covered above with large triangular trenchant scales disposed quincuncially, and overlapping each other like tiles. Toes five, armed with robust claws. Body endowed with the faculty of rolling itself up more or less into the form of a ball.

Dental formula: — 0.

Habits, Food, &c.—The Pangolins are slow in motion, and live on worms and insects, especially termites and ants, which they seize by means of their extensible and glutinous tongue.

Asiatic Pangolins.

Manis pentadactyla, Indian, Broad-tailed, or *Short-tailed Manis, Manis brachyura* of Erxleben, and probably the *Phattage* of Ælian (xvi. 6).

Description.—Head small, pointed, and conic; muzzle elongated and narrow; body rather stout; tail short and very broad at its base; dorsal scales disposed in longitudinal rows to the number of eleven; under part of the body, head, and feet naked; some long fair-coloured hairs spring from under the scales. Middle claw of the forefeet far exceeding the others in its proportions.

Locality, Food, &c.—The East Indies, coast of Tranquebar, &c. Feeds much on termites, or white ants, for the destruction of whose conical nests the great middle claw is admirably adapted. Thunberg states that it is found much in Ceylon, especially near Negumbo. The Dutch call it the *Negumbo Devil*, and the Cingalese *Caballe*. Its flesh was given to the sick to eat by way of remedy. Thunberg further informs us that the inhabitants have a method of making a hole in its skin with a knife, and thus of guiding and governing the animal at their pleasure, the point of the knife, which is kept in the hole, goading and irritating him. The cruelty of this proceeding does not however seem to have struck the traveller. The *Land Carp* is also an Asiatic name for this species. It is the *Kuwlee Manjar*, or *Tiled Cat* of the Muhrattas, according to Colonel Sykes, who notices it as very common in Dukhun (Deccan), and living on white ants. Mr. Hodgson, in his catalogue of the quadrupeds of Nepâl, mentions a new species of *Manis* allied to *Manis Javanica*, Desm., as being of frequent occurrence in the hills of the lower region, and in the mountains of the central tract. (*Zool. Proc.*, 1830, 1831, and 1834.)

African Pangolins.

The *Phatagin* of Buffon appears to be the *Long-tailed Pangolin* (*Manis tetradactyla*, Linn.; *Manis macroura*, Erxleb.). This species is from two to three feet in length, and the tail is twice as long as the body; the scales are pointed.

Locality.—Senegal, Guinea, &c.

But we shall illustrate the African Pangolins by the *Manis Temminckii* (Smuts).

Mr. Bennett described this species from a specimen in the collection made by Mr. Steedman in South Africa; and he stated that his object in calling the attention of the Society to it was to point out the external characteristics of a species known to its original describers by its skeleton alone and a few detached scales; and he characterised it as

Manis with a rather short head, a rather wide body; the scales large, and in eleven rows; the tail as long as the trunk, rather less than that in width, and hardly narrower at the subtruncate apex. Length 25¼ inches; of the tail 12 inches; width of the back 8 inches; of the tail near the apex 5 inches.

Mr. Bennett observes that the most remarkable features of this animal are the shortness of the head, the breadth of the body, and the breadth of the tail, which is nearly equal to that of the body, and continues throughout the greater part of its extent of nearly the same width, tapering only slightly towards the end, where it is rounded and almost truncate. Mr. Bennett further remarks that a peculiarity in the distribution of the scales of *Manis Temminckii* is the cessation of the middle series of them at a short distance acticular to the extremity of the tail, so that the last four transverse rows consist of four scales each, each of the preceding rows having five. (*Zool. Proc.*, 1834.)

Dr. Smith describes it as having the scales pale yellowish-brown, the colour lightest towards their points, many of which are marked with a longitudinal yellow streak; parts not covered with scales, dusky brownish-yellow. Eyes reddish brown; muzzle black. Nails of the fore-feet a pale dull yellow; those of the hinder ones brownish yellow.

The same author points out that *Manis Temminckii* is easily to be distinguished from any of the other species yet described, simply from the central row of scales upon the upper surface of the tail terminating some way behind its point. From *Manis pentadactyla*, Lin., the species to which it bears most similarity, it is moreover to be distinguished by all its scales being proportionally larger, and by those on the head being shaped and disposed differently. The greater breadth of the tail and the more divergent direction of its marginal plates, also afford marked characters by which the species is easily to be recognised from *Manis pentadactyla*.

Locality.—Mr. Bennett gives Latakoo. Dr. Smith says that only one solitary specimen of this species was obtained by the Expedition before reaching 26° S. lat., and but two more between that parallel and the tropic of Capricorn, though others were known to have been captured in the latter tract, while the travellers were actually traversing it. He thinks it very questionable if the animal be so rare in nature as the result of their experience might incline men to believe. He is of opinion that its extreme scarcity probably arises from its having long been zealously sought after by the natives, who cherish a belief that it either has some influence upon cattle, or, at least, that certain observances in respect of it have an effect upon them. Whenever a specimen is secured it is submitted to the fire in some cattle-pen, apparently as a burnt offering, for the increase of the health and fertility of all cattle which may afterwards enter that fold. Dr. Smith states, that not many years ago a specimen was captured in the northern part of the Cape colony, which renders it probable that the species was, at one time, scattered over the whole of South Africa, and that its almost total disappearance from the more southern districts has arisen from causes such as are now operating to effect a similar result in the interior. Here we have another cause for the obliteration of a species. Intolerance of their aggressions has wrought up the shepherd or the agriculturist to the destruction of some; but, in this case, a species is probably dying out under the influence of a superstition.

Habits, Food, &c.—Dr. Smith relates that when *Manis Temminckii* is discovered, it never attempts to escape, but instantly rolls itself up into a globular form, taking especial care of its head, which is the only part that is easily injured. Ants constitute its chief and favourite food, and these it secures by extending its projectile tongue into holes which may exist in the habitations of these insects or which it may itself form; and when, by means of the glutinous matter with which its tongue is covered, a full load has been procured, a sudden retraction of the retractor muscles carries both into its mouth, after which the ants are immediately swallowed. (*Illustrations of the Zoology of South Africa.*)

Manis Temminckii (from Smith).

FOSSIL PANGOLINS

M. Schleiermacher called the attention of Cuvier to a bone of which he sent the great French zoologist a plaster-cast. This bone had been found (together with many unusual remains of *Rhinoceros*, *Mastodon*, *Hippopotamus*, and *Tapir* near Eppelsheim, in the canton of Alzey, in that part of the ancient Palatinate belonging to the grand-duke of Hesse) in a dike whence sand and gravel were dug, which seemed to have been accumulated by the alluvium of the Rhine. Cuvier was soon satisfied that this bone was the ungueal phalanx of an Edentate mammiferous quadruped, and came to the conclusion, which has not been disputed, but on the contrary entertained by many less qualified to judge, that it belonged probably to a Pangolin of gigantic stature. Taking this ungueal bone for his basis, with far less material than he had for his opinion who ventured to pronounce 'ex pede Herculem,' Cuvier measured the animal to which it must have belonged as having extended to the length of twenty-four feet. Nor will this inordinate length stagger those who know the enormous proportions which characterised some of the extinct Saurians.

Geological Position.—Tertiary. Miocene of Lyell.

PANGUTARAN. [SULU ARCHIPELAGO.]

PANICLE is a kind of inflorescence, or arrangement of flowers, in which the axis is divided into a number of lateral branches, each of which is again subdivided into other branchlets. Examples of it will be found in the Lilac, the Agrostis stolonifera, and the Horse-chesnut.

PA'NICUM, a genus of grasses the name of which is applied to one of the species (Millet) by the Romans, and which, Pliny states, is so called from its flowers being in a panicle; though others derive the name from *panis*, bread, from its uses as such. The genus contains a very large number of species, which abound in the hot parts of the world, though a few extend to higher latitudes and ascend the cool mountains of hot countries. They are chiefly valuable as pasture grasses, and for their seeds, which form a large portion of the food of the poorer classes of many nations, and thus engage a considerable share of the attention of the agriculturists of those countries.

The genus Panicum is distinguished by having a two-flowered spikelet, with the lower flower masculine or *neuter*, and the upper hermaphrodite. Glumes two, unequal, concave, blunt. *Masc.* Paleæ two, stamens three, sometimes neuter, the upper palea and the stamens abortive. Fertile flowers, paleæ two, unequal, concave, the lower one embracing the upper. Scales two. Stamens three. Styles two, ovary sessile.

P. miliaceum, or Millet, is the best known species, being cultivated in the south of Europe as well as in tropical countries. Two varieties are well known, one brown, the other yellow-coloured, imported from the Mediterranean, chiefly for feeding poultry, but forming in the south of Europe as well as in India a portion of the food of the inhabitants. In the latter country it is cultivated in the cold weather with wheat and barley, and the only one of the small grains that is so at that season of the year. It is the *cheena* of the Hindus, Arab *dukhun*, Persian *arzun*. *P. Miliare* is another species generally cultivated on an elevated rich soil in the peninsula of India; the seed is one of the sorts of dry or small grain which forms an article of diet of the Hindus who inhabit the higher lands, and cattle are fond of the straw.

P. frumentaceum, which is the *shama* and *sawank* of the natives of India, is a wholesome and nourishing grain, and forms there an article of diet chiefly of the lower classes. There are several varieties of it, which yield from 50 to 80 fold; it delights in a light, tolerably dry, rich soil; the same ground yields two crops between the first of the rains in June, July, and the end of January, in the Circars, but only one crop in the northern provinces. Besides these, which are the most commonly cultivated species, the grains of other species of Panicum growing in a wild state are collected, and form articles of diet with the poorer classes of the natives of India, as of *P. floridum* (*burlee*), *P. Helopus* (*hoorre*), *P. hispidulum* (*dhand*).

The uses of this genus are not confined to its grain, for the herbaceous part of several species forms the most valuable pasture grasses of the hot countries both in the old and new world. Some of the species of Panicum of the Brazils are of gigantic stature, and yet tender and delicate in their herbage. The Capim de Angola of Brazil grows 6 or 7 feet high, and other equally gigantic species constitute the field crops on the banks of the Amazon; while *P. maximum*, or Guinea grass, forms the most valuable pasture for cattle in Jamaica. This is said to have been introduced into that island from the coast of Africa, the seeds having been transmitted as food for some birds which were sent to Chief Justice Ellis. The straw of several of the species is esteemed as fodder for cattle in India, but no pasture grass in any country is probably more highly thought of than the *Doob* of India, which by the Brahmins is held sacred to Ganesha (Janus?) under the name of *doorwal*. This is fortunately the most common species throughout India, and forms probably three-fourths of the food of their horses and cows. It is seldom cultivated, but Europeans in the northern parts frequently form lawns by planting small pieces of this grass, which forms excellent hay. The usual mode of obtaining it is to send out the grass-cutters into the uncultivated parts of the country, who scrape off the ground the creeping stems and leaves of this species, which is easily distinguished by its smooth and creeping habit; its spikes being fascicled and digitate, filiform, from one to two inches long, with the flowers disposed in two rows on the under side. It is the *Panicum Dactylon* of botanists, and occurs also in England.

PÂNINI, the most celebrated of the Sanscrit grammarians, is said to have been the grandson of the inspired legislator Dêvala, and lived at so remote an age that he is reckoned among the fabulous sages mentioned in the *Purânas*. (See Colebrooke, *Asiat. Res.*, vii., p. 202.) With regard to his death we have the following tradition in the *Hitôpadêça*:—'It is related that the valuable life of Pânini was destroyed by a lion.' The Indians consider him as their most antient grammarian, but his great work is confessedly derived from earlier treatises on the same subject; he often quotes his predecessors Sâcalya, Gârgya, and others; and it appears from a passage in the *Bhagavad-Gita*, that the nomenclature of grammar existed when the great epic poem, the *Mahâ-Bhârata*, was composed, unless the following line is an interpolation of a later age: *aksharânâm-a-kâras asmi; dvandvas sâmâsikasya-cha*, 'I am the A of letters,' says Chrishna, 'and the copula which connects the elements of the compound word.' (*Bhag. Git.*, x. 33.)

Pânini's grammar consists of 3996 short aphorisms, or *sutras*, divided into eight books, in which the rules of grammar are delivered with such oracular brevity and obscurity that they need a commentary to render them intelligible even to the learned Indians. Besides the *Câricâ* of Bhartrihari, a brother of king Vicramâditya [AMARA], there were the following treatises, written expressly to illustrate it: 1, the *Bhattikâvya*, which was nominally a poem describing the adventures of Râma, but really a collection of all the defective and anomalous forms of words in the language, published at Calcutta, 1826; 2, the *Mahâ-Bhâshya*, or 'great commentary,' by Patanjali.

A new edition of Pânini is in the course of publication in Germany, with the following title: 'Pânini's acht Bücher grammatischer Regeln; herausgegeben und erläutert von Dr. Otto Böhtlingk,' Bonn, 1839. The first volume, which is all that is published as yet, contains the Sanscrit text of Pânini's *Sûtras* with the native scholia; the second volume is to contain an introduction, a German commentary, and indexes.

PANI'NI, PAOLO, an eminent painter of architecture, was born at Piacenza (Placentia), in the year 1691. When prosecuting his studies at Rome, he took peculiar pleasure in designing every vestige of antient magnificence, the ruins of the finest Roman edifices, and some of those buildings which are still the ornaments of modern Rome. He formed his style of composition and his entire manner after the works of Ghidolfi, in which he was so successful that he soon excelled all his contemporaries in that department of the art. His paintings are universally esteemed for the grandeur of the architecture, the correctness of the perspective, and the clearness of the colouring. His figures also are designed with taste, and cleverly grouped. In general however his figures are rather too large for the buildings, which detracts from the grandeur of the composition, and is quite contrary to the practice of Ghidolfi. In his latter time his works were distinguished by freedom and breadth of touch, but in colouring and effect they are more feeble than his earlier performances.

There are several pictures by Panini at Rivoli, a country-house belonging to the king of Sardinia, representing views of that seat and the environs.

PANIO'NIUM. [IONIA.]

PANJAB. [HINDUSTAN, vol. xii., p. 220.]

PANNAH. [HINDUSTAN, p. 215.]

PANNO'NIA, the name of a province of the Roman empire, was bounded on the north and east by the Danube, on the south by Illyricum and Mœsia, and on the west by Noricum. It was separated from Mœsia by the Savus (Save), and from Illyricum by an imaginary line drawn a few miles south of the Save; but it is difficult to determine the boundaries between Noricum and Pannonia, as they differed at various times. Under the early times of the Roman empire Pannonia could not have extended much farther west than the Narabo or Arrabo (Raab), if Pliny (iii. 27) is correct in placing Sabaria in Noricum; but in later times the two provinces appear to have been separated by Mount Cetius (Kahlenberg). Pannonia would thus correspond to Sclavonia, parts of Hungary, Lower Austria, Styria, Croatia, and to those parts of Turkish Croatia, Bosnia, and Servia which immediately touch upon the Save.

The Pannonians are called Pæones by some of the Greek writers, but this appears to have been clearly a mistake arising from the similarity of the names. The Pæones were probably a Thracian people; while the Pannonians belonged to the Celtic, or perhaps the Germanic race. They were first attacked by Augustus, B.C. 35 (Dion Cass., xlix. 36, 37; Liv., *Ep.*, 131), and were subdued during his reign by Tiberius, and reduced to the form of a province. (Vell. Pat., ii. 110, et seq.) Pannonia is not mentioned by name in the division of the Roman empire made by Augustus, but it was probably included among the Eparchies of the Cæsar. (Strabo, p. 840.) We learn from Tacitus (*Ann.*, i. 16), that at the death of Augustus there were several legions stationed in Pannonia, which was then regarded, and continued to be so till the end of the Roman empire, as one of the most important provinces of the empire, on account of its bordering on the powerful nations of the Quadi and Iazyges.

Under the early Roman emperors Pannonia only formed one province; it was afterwards divided, but at what time is uncertain, into two provinces, Pannonia Superior and Pannonia Inferior, the former comprising the western, and the latter the eastern part of the original province. They were separated from one another by a line drawn from the point at which the Arrabo flows into the Danube, southward to the Save. A new division of the provinces was made by the emperor Galerius. The southern part of the two former provinces, comprising the country between the Drave and the Save, was formed into a new province, and called Savia, or Pannonia Secunda; but the northern part was still divided into two provinces as before; the western part retained the name of Pannonia Superior, or Pannonia Prima, but the name of the eastern province was changed into that of Valeria, in honour of the wife of Valerius, who cleared a great portion of the land in the north of Pannonia of its woods, and connected the lake of Peiso or Pelso (Neusiedler See) with the Danube by a canal. (Aurel. Vict., *De Cæsar.*, c. 40.) Pannonia was thus divided into three provinces, which division appears to have continued till the downfal of the Roman empire.

The principal rivers of Pannonia were the Narabo or Arrabo (Raab), the Dravus (Drave), and Savus (Save), all of which flow into the Danube. The two most important ranges of mountains were the Pannonii Montes, a continuation of the Sarmatian range, which passed through the northern part of the province in a south-westerly direction, and joined Mount Cetius; and the Claudii Montes, which separated the valleys of the Drave and the Save.

Very little is known of the position of the different tribes which inhabited Pannonia. According to Strabo (vii., p. 314), their names were the Breuci, Andizetii, Dasnones, Diasiones, Purusti, Mazæi, and Dæsitiatæ. Pliny (iii. 28) has given a list of the Pannonian tribes, of which, he says, the principal were the Serretes, Serrapilli, Iasi, Andizetes, Colapiani, and Breuci, the first four of which he places in the neighbourhood of the Drave, and the last two in that of the Save. The powerful nation of the Boii dwelt in the north-western part of the province; and after their extermination by the Getæ that part of the province was called Deserta Boiorum. (Plin., iii. 27.) The Scordisci and Taurisci, who also dwelt in Mœsia and Noricum [NORICUM] respectively, are said by Pliny (iii. 28) to have been separated from one another by the Mons Claudius, though he does not mention them in his enumeration of the tribes which inhabited the province.

Pannonia possessed several towns of importance, the inhabitants of which appear to have principally depended for their support upon the numerous legions which were quartered in different parts of the province. Following the course of the Danube, the first town we come to after leaving Noricum is Vindobona (Vienna), called Vianiomina by Pliny (iii. 27), who places it in Noricum. At the time of Ptolemy it was called Juliobona, and was the station of a legion. It is called by most later writers Vindobona; but in the 'Notitia Imperii' it is written Vindomana. The only town of importance below Vindobona on the Danube is Carnuntum, which, in the early part of the Roman empire, was the most important place in the north of Pannonia. It is mentioned by Velleius Paterculus (ii. 109) and Pliny (xxxvii. 11, sec. 2). It appears from the account of Pliny to have been a place of considerable commercial importance. The amber which was collected in the northern part of Europe was brought to this town, and thence conveyed to the different parts of the Roman empire. It was the head-quarters of the army of Marcus Antoninus in the war which he carried on with the Marcomanni (Eutrop., viii. 6.) In the time of Ammianus Marcellinus (xxx. 5) that is, in the latter part of the fourth century, it was almost without any population. Its ruins are in the neighbourhood of Altenburg. We learn from an inscription found in this spot that it was a municipium ('Probus Devotus Municipi Carnuntensis').

Below Carnuntum on the Danube was Brigetium or Bregetium (Szöny), called by Ammianus Marcellinus (xxx. 5) Bregetio, the station of a Roman legion, where the emperor Valentinian died, while making preparations for a war against the Quadi. Following the course of the Danube, we next come to Aquincum or Acincum (Buda or Ofen), the principal town in the province of Valeria and the station of a legion. The Romans had a military station on the other side of the river, which was called Contra Aquincum. South of Acincum on the Danube, in the province of Savia, was Malata or Milata, afterwards called Bononia (Amm. Marc., xxi. 9; xxxi. 11); and below it were Acumincum or Acimincum (Peterwardein) and Taurunum (Semlin), the most easterly town in the province, near the confluence of the Save and the Danube.

The most important towns in the southern part of the province were Siscia (Sissek), Cibalæ or Cibalis (Palanka), and Sirmium (Sabacz), all on the Save. Siscia, which was upon the borders of Illyricum, was the most important town in Pannonia in the time of Augustus. It is called Segestica by Strabo (vii. 313), but Pliny (iii. 28) gives this name to an island near Siscia, which is formed at the confluence of the Colapis and the Save. Dio (xlix. 37) also calls the town Siscia. We learn from Pliny that it was a colony. Cibalæ or Cibalis was situated at a considerable distance below Siscia. It was memorable for the defeat of Licinianus by Constantine, and was the birth-place of the emperor Gratianus. (Amm. Marcell., xxx. 24.) Sirmium, which was below Cibalæ, was, under the later Roman emperors, the principal town of Pannonia. It formerly belonged to the Scordisci, and is mentioned by Strabo (vii. 314) and Pliny (iii. 28), the latter of whom states that it was situated at the confluence of the Savus and Bacuntius. It was the residence of the Roman emperors when they visited the province; and we learn from Ammianus Marcellinus (xxi. 10) that there was an imperial palace in the town.

On the Drave, near the confines of Noricum, was Petovio or Pætovio (Pettau), which is mentioned by Tacitus (*Hist.*, iii. 1) as the winter-quarters of the thirteenth legion. Below Pætovio on the Drave, were Jovia ([illegible]), and Mursia (Essek), a colony founded by Hadrian. (Steph. Byz.) At Mursa the fleet of the Lower Danube was stationed, and near it Magnentius was defeated by Constantius. (Zosimus, ii. 43.)

The only town of importance in the north-western part of the province was Sabaria (Steinamanger), a Roman colony founded by the emperor Claudius. (Plin., iii. 27.)

PANOPTICON. [BENTHAM; PRISON.]

PANORAMA (from the Greek word πᾶν, all, and ὅραμα, a view), a picture showing a view completely around the spectator. This ingenious pictorial contrivance was first devised by an English artist, Robert Barker, about the year 1788, and is not so much a new mode of painting—the process itself being similar to scene-painting or *in distemper*—as a novel application of it. Contrary to the diorama [DIORAMA], the panorama forms the surface of a hollow cylinder, or rotunda (whence it is frequently called in German *Rundgemälde* or *Rundbild*,—cyclorama), in the centre of which is a detached circular platform for the spectators, covered overhead to conceal the skylight, and thereby increase the illusion and give greater effect to the painting itself. This latter is not painted on the walls, but upon canvas, like the scenes of a theatre, and afterwards fixed up, in order that the views may be changed, and a fresh one may be in progress while another is open for exhibition. Yet although there is nothing whatever particular in regard to the execution or process of such pictures, they are attended with difficulties which can be mastered only by practice and experience. The first of these arises from the circumstance that the artist cannot either concentrate his light or adapt the direction of it arbitrarily as best suits his purpose, but while portions of his view will be entirely in sunshine, the opposite one will be almost a mass of shadow; the second is the difficulty of representing on a curved surface the straight horizontal lines of buildings; the third and greatest of all is, that there can be no single fixed point of sight, since the eye traverses around the whole circle of the horizon. Hence it might be supposed that many parts of such a picture would appear, if not quite distorted, more or less out of perspective. Yet such is not the case, no doubt partly because the eye accommodates itself to certain principal points fixed upon by the artist as centres of vision, and on account of the optical fascination attending the whole. The subjects generally chosen are views of cities, or interesting sites, whose entire locality and buildings may thus be vividly placed before the eye in a manner no less instructive than it is interesting.

One of the largest panoramas hitherto attempted is the view of London, at the Colosseum in the Regent's Park, as seen from the top of St Paul's, whose dome and western towers the spectator sees beneath and before him; and so far the deception is exceedingly well managed, but owing to the very great height of the painting, the lower part of it is not sufficiently lighted. In fact there is still room for considerable improvement as regards the mode of showing such views, since nothing would be easier than to get rid of what is now suffered to interfere with the illusion. The staircase should invariably be made to ascend to the very centre of the platform, and the latter should be made to represent a circular temple with columns supporting its roof, and placed upon a parapet of such height and breadth that the spectator could not look down, clear over it, to see the lower termination of the painting. Or perhaps a circular or octagonal room with large arched window-like openings on its sides would be still better, since the platform would thus be comparatively dark, while the picture as seen through the openings would acquire great brilliancy, and the illusion of the whole be greatly heightened.

PANORMUS. [PALERMO.]

Coin of Panormus.

British Museum. Actual size.

PANSA. [ANTONIUS.]

PANSY, a corruption of the French word *pensée*, is a name now chiefly applied to the garden varieties of Viola tricolor, Altaica, and others, which are commonly cultivated under the name of Heart's-ease. These plants, being all nearly allied to each other, have proved an abundant source of hybrids, which, by repeated crossing and selecting, have at length been so much improved in their appearance that it is not uncommon to meet with single flowers as large as a penny piece, although the wild blossoms of Viola tricolor will hardly cover a sixpence. When skilfully managed, they are great ornaments of the flower-beds in a garden, but they are short-lived, and require to be continually renewed by seeds or cuttings. They love damp rich soil, not too much exposed to the sun, and are thought to acquire the greatest health and beauty when planted in beds of light rich earth upon a thick substratum of cow-dung, into which their roots will quickly penetrate.

PANTELLARIA. [SICILY.]

PANTHE'ON, a very celebrated and well-preserved monument at Rome, of which Valerius of Ostia is said to have been the architect. It consists of a rotunda with a noble Corinthian octastyle portico attached to it, and resembles in its general mass the Colosseum in the Regent's Park, London, except that the body of the latter building is a polygon of sixteen sides, and its portico (a Grecian Doric hexastyle) is only a single intercolumn in depth. That the portico of the Pantheon was erected by Agrippa, the son-in-law of Augustus, is testified by the inscription on the frieze: 'M. Agrippa, L. F. Cos. Tertium Fecit.' Yet some have supposed that he merely made that addition to the previously erected rotunda. Hirt, in his 'Historico-Architectural Observations on the Pantheon,' very reasonably argues that, there being no direct proof to the contrary, the whole structure may safely be assumed to have been erected according to one original plan, because without the portico it would have been a lumpish and heavy mass. Hirt further rejects the idea of the rotunda having been originally not a temple, but an entrance to public baths; it is certain that circular plans were greatly affected by the Romans both in their temples and other buildings, on which account their architecture presents a variety that does not occur in that of Greece. Despoiled as it is of rich ornaments, gilded bronze-work, and statues, of which it was plundered before the building was consecrated as a Christian church in the seventh century,—further, disfigured by two ugly belfries erected by Urban VIII., whose family name Barberini gave rise to the memorable pasquinade, 'Quod non fecerunt barbari fecere Barberini,'—the Pantheon is still the pride of Roman architecture, and well justifies Akenside's character of it:—

> 'Mark how the dread Pantheon stands
> Amid the toys of modern hands,
> How simply, how severely great!'

It is by far the largest circular structure of antient times, the external diameter being 188 feet, and the height to the summit of the upper cornice 102, exclusive of the flat dome or calotte which makes the entire height about 148 feet. The portico (103 feet wide), as has been said, is octastyle, yet there are in all sixteen columns, viz. two at the returns, exclusive of those at the angles, and two others behind the third column from each end, dividing the portico internally into three aisles or avenues, the centre one of which is considerably the widest, and contains the great doorway within a very deep recess, while each of the others has a large semicircular tribune or recess. But although, independently of the recessed parts, the portico is only three intercolumns in depth, its flanks present the order continued in pilasters, making two additional closed intercolumns, and the projection there from the main structure about 70 feet; which circumstance produces an extraordinary air of majesty. The columns are 47 English feet high, with bases and capitals of white marble, and granite shafts, each formed out of a single piece. The interior diameter of the rotunda is 142 feet, the thickness of the wall being 23 feet through the piers, between the exhedræ, or recesses, which, including that containing the entrance, are eight in number, and each, except that facing the entrance, is divided into three intercolumns, by two columns (34·7 feet high) between antæ or angular pilasters; while the intermediate piers are occupied by eight smaller projecting tabernacles. But as, besides being repaired and altered by Septimius Severus, the interior has undergone many changes, or rather corruptions, it is hardly possible now to determine what it originally was. Hirt supposes that all the recesses were arched, and, except the one for the entrance, contained colossal statues of Roman deities, and that there were no columns in front of them, but a single insulated column on each side, with the entablature of the piers breaking over it, whereby the entire circumference was divided into sixteen equal intercolumns formed by as many columns. Yet the projection of the columns, and the breaks in the entablature, as well as the interruption of the latter by the arches, would have destroyed the unity and simplicity of the plan. Besides which the effect of the columns and narrow intercolumns in the recesses, and the effect of shadow thus obtained, would have been lost. The greatest defect of all is the tasteless and even barbarous modern decoration of the space between the cornice of the order below, and that from which the dome springs. Had this space been reduced by considerably augmenting the principal cornice, converting it into a cornicione as a finish to the cylindrical portion of the building, and the remainder been divided into oblong pannels over the recesses, filled with reliefs, there can be little doubt that the general appearance would have been materially improved, and that with greater simplicity much greater richness also would have been obtained. The dome has five rows of coffers (now stripped of their decorations) and a circular opening in the centre, 26 feet in diameter, which not only lights the interior perfectly, but in the most charming and almost magical manner. Indeed there has scarcely ever been but one opinion as to the captivating effect thus produced, and the exquisite beauty of the whole, as regards plan and general proportions. As an interior, Grecian architecture has nothing whatever, we will not say that rivals, but that even approaches it; nor does it say much for modern architects, that, with such an example before them, they should scarcely ever have taken a lesson from the Pantheon in regard to those qualities which constitute its excellence, namely, the richness of columniation and great depth of the portico, and the simple majesty of proportion and captivating distribution of light in the interior, producing an effect so greatly superior to that of any modern dome or cupola.

It was Michael Angelo's boast that he would suspend the dome of the Pantheon aloft over the centre of St. Peter's; and if he meant no more than a dome equal in magnitude to the whole interior of the Pantheon, he was right; but in every other respect his dome is totally dissimilar from it. Instead of being within a capacious rotunda of which the vaulting itself occupies one half the entire height, you look up into that of St. Peter's and most other modern ones from a great distance below, and although that sort of effect may be good of its kind, and allowable for the sake of variety, it is totally different from the other, to say nothing of the quite contrary effect of light, which, instead of diffusing itself in a brilliant stream from the summit, enters below and in all directions, so as to produce a flickering glare. In our own St. Paul's for instance, the dome exhibits within only a sort of darkness visible—a murky gloom through which may be discerned the twinkling of the lantern on its summit. Almost the only tolerably correct imitation of general character and effect of the interior of the Pantheon, is the rotunda of the museum at Berlin, by Schinkel; although not half the size, its proportions are nearly similar, with the exception that the cylindrical part is a little loftier as compared with the dome, the diameter being 66 feet, the entire height 70, and that to the top of the cornice 42. Like the Pantheon, it is lighted by a single aperture in the centre of the dome, 22 feet in diameter, and glazed with crystal-glass of enormous thickness. The Halle aux Blés at Paris deserves also to be mentioned as an instance of a rotunda resembling in its proportions the interior of the Roman Pantheon, the central area being 128 feet in diameter, and the height to the summit of the dome somewhat less. The library of the University of Virginia, which was planned by the late President Jefferson, is (externally) a copy of the Pantheon, of about one half the linear dimensions. Canova's church at Possagno is also an imitation of the Pantheon in its plan and dome: further mention is made of that and some other structures of the same kind in the article ROTUNDA.

For further particulars respecting the dimensions and construction of the dome of the Pantheon, and several modern ones, the reader is referred to DOME.

PANTHER. [LEOPARDS, vol. xiii., p. 430, et seq.]

PANTODA'CTYLUS, the generic name given by MM. Duméril and Bibron to the form known generally as *Trachydosaurus scincoides* (*Ptychopleures*).

PANTOGRAPH, sometimes improperly called **PENTAGRAPH**, is an instrument employed in copying maps, plans, and other drawings.

The annexed diagram represents that most commonly in use.

It is composed of four brass rules or bars, jointed to each other at the points B D E F. These joints require to be executed with the utmost care, as upon the smoothness and steadiness of their motion the accuracy of the instrument principally depends. In those of the best construction there is a small metal cock screwed to the lower bar of each joint, which supports the upper end of the axis upon which it turns. This is a material improvement upon the common flat compass joint, as, besides lengthening the axis, it gives additional strength to the bar where it most requires it. A joint of this construction is shown in *fig*. 2.

At the point C is fixed a small tube which carries the tracing point, so fitted as to move freely within it, but without shaking; *fig.* 3 represents the tracer within the tube.

Fig. 1.

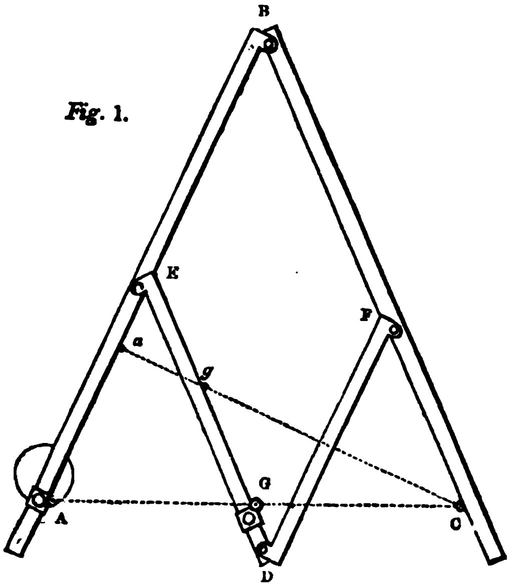


Fig. 2.

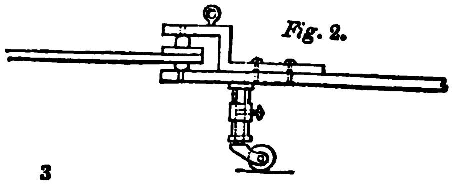
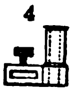


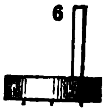
3

4



5

6



The bar E D and the lower part of the bar A B are furnished each with a tube, *fig.* 4, similar to that at C, but moveable on the bar, with a similar screw to fasten it down at any required point. *Fig.* 5 is the pencil stem, which fits either of the tubes in the same manner as the tracer; on the top of the stem is a cup to receive a small weight to keep it down upon the paper, and the lower end carries a pencil, or, which is better, a 'Mordan's point.' A silk cord is attached to the pencil stem, carried through eyes made for the purpose, over the joints E B F, one of which is shown on the top of *fig.* 2, and fixed in a notch in the top of the tracer, *fig.* 3, so that the pressure of the thumb upon the cord lifts the pencil from the paper when required. *Fig.* 6 is a flat leaden weight with a brass stem rising out of it, which fits in the tubes in the same manner as the pencil and tracing point; this is called the fulcrum, as being the point upon which the whole instrument moves; the weight has three or four fine points on its under surface to keep it from shifting upon the paper. The whole instrument is supported by six revolving feet or castors, which should move very freely in all directions. One of these castors is shown under the joint, *fig.* 2. The pin or fulcrum is placed near the edge of the weight, so as to allow room for the castor to work when the fulcrum is near the points A or D.

The proportion of the bars is of no consequence, so that E D is equal to B F and E B to F D, in which case they will always form a parallelogram, by which name the instrument is sometimes called. Now if the tracer at C is carried over the lines of the plan, the fulcrum-tube being fixed at A, and the pencil-tube at G, the pencil will make an exact copy of every line, but only half the size of the original, which may be proved in the following manner.

The points A, G, and C are capable of being brought close together, and when the instrument is open, as in the figure, G is exactly half way between C and A; C then travels twice as quickly as G in the direction A G C, so that to whatever extent the pantograph may be opened, G and C being considered as points in a lever of which A is the fulcrum, it will be seen that if C is made to describe an arc of a circle of any radius, G at the same time is describing an arc of a circle of half the radius, so that C moves in a direction perpendicular to A G C twice as fast as G. Now it was shown above that it moved twice as fast as G in the direction A G C, and as by the composition of these two motions, all lines, whether rectilinear or curved, are produced, it follows that the pencil at G will produce a copy half the size of the original traced over by the point at C, as before stated.

To produce a copy one-fourth the size of the original, we must shift the pencil from G to *g*, and the fulcrum from A to *a*, *a g* being one-fourth the length of *a* C, and so on for all other proportions *less* than half, the constant rule being —'As the distance of the pencil from the fulcrum is to the distance of the tracer from the fulcrum, so will be the size of the copy to that of the original.' No calculation is required in practice, as the arms A E and E D are graduated for all proportions from one-twelfth to eleven-twelfths inclusive. If it be required to produce a copy *more* than half the size of the original, the fulcrum must be placed on the arm E D, and the pencil on A E, the rule above given still holding good, so that for a copy the *same size* as the original the fulcrum must be placed at G, and the pencil at A. It must be borne in mind however, that when the fulcrum is on the arm E D, the copy will be inverted.

Though the principle of this instrument is as simple and complete as can be imagined, yet it falls sadly short of perfection in practice.

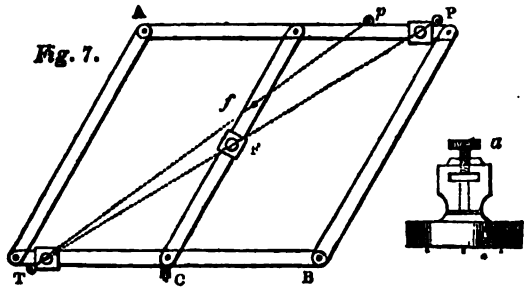
In the first place the numerous joints and castors, however carefully constructed, make it heavy to the hand in comparison with the unfettered pencil, and it requires much practice to be able to manage it so dexterously as to get those minute and gentle undulations, necessary not only to the beauty but to the utility of the drawing. The pencil too, constantly working upright, does not maintain that fine point which is required for distinctness of outline, and to these faults we must add inaccuracy of workmanship, however slight, the effect of wear, inequalities of the paper, and other accidents.

The best way to test an instrument is to reverse the position of the tracer and pencil, thus producing a copy larger than the original, when the defects will of course be exaggerated in proportion.

The pantograph however, though it cannot be depended upon for an accurate and finished copy, is of great service to the draughtsman, for by it may be marked off all the principal points through which to draw the lines of a plan with equal accuracy and infinitely greater facility than by any other means used for the purpose.

The annexed engraving represents a pantograph of very recent invention, which possesses some advantages over that before described.

Fig. 7.



In the first place, the fulcrum being in the centre, it requires but one castor, which is placed at C, and makes it work much lighter in hand than the old instrument, which has six, as before described; besides which these six castors are frequently a great source of annoyance by getting off the edge of the drawing-board and running over drawing-pins or any thing else which may happen to be in the way. Secondly, the shape of this instrument allows it to move as freely when nearly closed as when opened wide, which is not the case with the other. The simplicity of its construction renders description almost superfluous.

It is composed of six bars, moving freely about each other at the six points of juncture, so arranged with regard to length that A P and T B are always parallel to each other. F is the fulcrum, furnished with a socket and screw (*a*), through which the centre bar can be moved, and which can be fastened down at any of the graduations on that bar. This socket, with the bar, turns upon the pin rising out of the centre of the flat weight, as shown in the diagram. Now the tracer T, the fulcrum F, and the pencil P must always be in a straight line. To produce a copy the same size as the original, the fulcrum must be in the centre, and the pencil and tracer, as in the engraving, equidistant from the centres of their respective arms, and consequently from the fulcrum. For a half-size copy the pencil must be shifted half way up the arm to *p*, and the fulcrum to *f*, in the straight line T *f p*, and so on for any required proportion, which is apparent by a glance at the diagram. The rule laid down in regard to the other instrument holds good for this, the copy bearing the same proportion to the original as the distance of the pencil from the fulcrum does to that of the tracer.

In using the pantograph it is frequently necessary to copy the drawing in divisions, on account of the instrument not being large enough to extend over the whole surface at once. In this case the greatest care is requisite to join the lines of one division accurately to those of the adjoining division. The best way of effecting this is to hold the tracer down upon a point in the original by one hand, moving the fulcrum about with the other, until the pencil exactly coincides with the corresponding point in the copy. To ensure accuracy, this should be tried with three or more points, as the least deviation will throw the whole plan out of position.

In practice a large number of plans are copied of the same size as the original. The quickest method, which however requires great care, is to pin down a piece of transparent paper called tracing-paper upon the original, on which the lines are marked with a fine-pointed pencil. A piece of paper rubbed over with blacklead is then placed upon the paper intended for the copy, with the black side downwards, and the tracing-paper is pinned down upon it; the lines then are carefully traced over with a steel point, and the pressure transfers the blacklead to the drawing-paper beneath. The black paper is sometimes omitted, and the lines, traced by slight indentations only, are finished by hand, in the usual manner.

If it is required to reduce a plan, and the draughtsman does not possess a pantograph, the usual way is to divide the original and the paper for the copy, whatever the relative size, into the same number of squares, which will of course then bear the same proportion to each other as the surfaces of which they are divisions. The lines must then be set in singly, either by the assistance of the proportional compass or scale, or by a geometrical scale drawn for the occasion. The following is the best method we are acquainted with, and is dependent only upon the compass and T square.

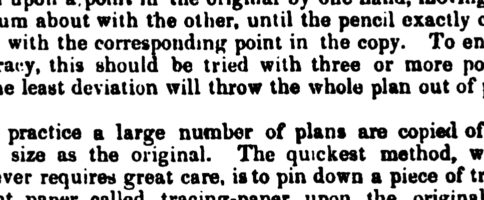


Fig. 8.

Draw a triangle in which A B is the base, and make A C bear the same proportion to C B as you wish the copy to bear to the original; take any distance on the original, and set it off from B on B C, draw a line parallel to A B, and that portion of A C cut off by such parallel will bear the required proportion to the distance set off on B C, as may be seen by the divisions 1 2 3 4 on the two sides of the triangle in the diagram. The triangle should be drawn in ink, and the distances, being marked in pencil, may be rubbed out when transferred to the paper.

PA'NTOMIME, the name of a species of dramatic performance in which the actors express themselves by gestures. The name is composed of two Greek words, meaning 'imitation of every thing.' Pantomimic acting, accompanied by music, has been in use among the Chinese, Persians, and other Oriental people from the oldest times. The Greeks introduced the pantomime in their chorusses, some of the actors dancing and gesticulating, accompanied by music, whilst others sang. (Lucian, *De Saltatione.*) The Romans had entire dramatic representations consisting of dance and gestures only, styled 'saltatio pantomimorum,' and some of their performers attained a high degree of excellence in the art. Two of them, Bathyllus and Pylades, in the time of Augustus, have been celebrated by the Roman writers.

In modern times pantomimic balls, representing an entire dramatic action or fable, have become a favourite scenic performance. The Tuscan Angiolini, in the last century, and after him Viganò, who died at Milan in 1821, have excelled in this species of composition. Noverre, in France, distinguished himself likewise in the composition of pantomimic 'ballets.' This kind of performance now forms generally an appendage to the opera, and especially the Italian opera.

Meursius, *Orchestra;* Signorelli, *Storia Critica dei Teatri antichi e moderni.*)

PAO'LA. [Calabria.]

PA'OLI, PASQUA'LE DE, was born in 1726 in the village of Rostino, in the jurisdiction of Bastia in the island of Corsica. In 1734 his father Giacinto de Paoli, together with Giaffieri, was proclaimed their leader against the Genoese by the revolted Corsicans, but after a struggle of several years, in which the adventurer Theodore figured, Giacinto was obliged by the French auxiliaries of the Genoese to give up the contest, and obtained leave in 1740 to withdraw from the island with his younger son Pasquale. [Corsica; Neuhoff.] Clemente the elder son remained in Corsica. Giacinto and his son went to Naples, where the father obtained a commission in a regiment formed chiefly of Corsican emigrants, and the son was placed in the military college of that capital, where he studied under able masters, amongst others the celebrated Genovesi. On leaving college young De Paoli obtained a lieutenant's commission in the Neapolitan service. Meantime a fresh revolt broke out in Corsica, under two chiefs, Matra and Gaffori, who gave full occupation to the Genoese for several years. In October, 1753, Gaffori was murdered by hired assassins, and the Genoese were suspected of having instigated the crime. The Corsicans now cast their eyes upon young Paoli, and invited him to come and put himself at their head. He did so, and was proclaimed, in a parliament of the representatives of the people, in July, 1755, captain-general of the Corsicans. During twelve years he baffled all the efforts of the Genoese, who lost every part of the island, except the maritime towns of Bastia, Calvi, San Fiorenzo, and Ajaccio, in which the Genoese garrisons were blockaded by the natives, and at last the Corsicans obtained possession of Ajaccio also. But Paoli had to encounter a more dangerous enemy than the Genoese, in the traitors among his own countrymen, headed by Matra, who, through jealousy or bribes, or both, excited a civil war, in which he was defeated and killed, and his brother was obliged to take refuge at Genoa. Meantime Paoli organised the island, and fixed its government and administration. He formed a legislative assembly, under the name of 'Consulta Generale,' of 500 deputies, elected by the body of the people, one for each commune the members were renewed every year; only freeholders twenty-five years old at least were qualified to be returned as deputies. The executive consisted of nine members, elected by the deputies. Paoli was the president of the executive, with the title of 'General of the Kingdom and Chief of the Supreme Magistracy of Corsica.' He had a body-guard which escorted him when he went out, to protect him against any attempt at assassination; but he would have no guard at the door of his apartments, trusting to the fidelity of six large fierce mastiffs which watched and slept in his room. A law of the legislative assembly forbade under severe penalties any person from speaking or writing against the general or the executive council. In 1764 Paoli established a university in the town Corte, the professors in which were paid by the nation, and the students taught gratuitously. The funds for the new university were supplied from a tax on the parochial clergy. The military force consisted of militia well trained to the use of arms; Paoli could collect 30,000 men in case of necessity. He also formed a flotilla, with which he annoyed the Genoese trade, and took possession of the island of Capraia. The whole public revenue of the island did not exceed one million of livres, or about 40,000 pounds sterling. In 17[illegible] Pope Clement XIII., at the request of Paoli, sent to Corsica a bishop with the title of Apostolic Visitor, in order to regulate the ecclesiastical affairs, which were in a state of confusion. This step, which had something of the appearance of a recognition of the independence of Corsica, greatly displeased the republic of Genoa, which offered a reward of 3000 crowns to any one who should arrest the bishop and deliver him over to the Genoese authorities, forbidding at the same time all subjects of the republic to obey his mandates. The pope published an edict against the resolutions of the *[illegible]* which he characterised as iniquitous and an insult to the apostolical authority. The quarrel lasted for some years, and employed the pens of jurists and controversialists on both sides.

Genoa, despairing of ever recovering the sovereignty of Corsica, resolved on giving up the island to France. This was effected by the treaty of Versailles in 1768, a dishonourable and disgraceful contract to both parties. Paoli loudly and eloquently appealed to all Europe against the cession, but no one interfered in favour of Corsica. The French landed a large force in Corsica, well provided with artillery and ammunition, under the command of Count Marbœuf. Paoli determined upon resistance, and was seconded by the whole population, including the women. The Corsicans fought desperately: though overwhelmed at first by superior forces, they defeated the French with great slaughter on the banks of the Golo, and again on the 9th October, 1768, they routed the main body of the enemy, commanded by Marbœuf in person, with the loss of two thousand men. In the following year large reinforcements came to the French from Toulon under General de Vaux. In May, 1769, a general battle took place, in which the Corsicans, after fighting bravely, were completely routed near Pontenuovo. The French entered Corte, and overran the whole island. Most of the communes submitted to the conquerors. Paoli, with many followers, retired to Portovecchio, from whence he sailed in an English vessel for Leghorn, where he was kindly received by the grand-duke Leopold. Paoli afterwards repaired to England, where he remained till 1789, when Mirabeau moved in the National Assembly the recall of all the Corsican patriots who had bravely fought for the independence of their country. Paoli repaired to Paris, where he was received with acclamations, and in the hall of the Assembly he promised fidelity to France under the new order of things. He was presented to Louis XVI., who made him lieutenant-general and military commandant in Corsica. He was received in his native island with the greatest enthusiasm, and was placed at the head of the national guard. Paoli acted faithfully towards the constitutional monarchy of France; but when the violent revolutionists overthrew that monarchy, Paoli drew back, and separated himself from the French party. His nature, sincere and steady of purpose, revolted from the injustice, the oppression, and the immorality of the Convention. He was soon accused before that assembly, and his name was placed on the lists of proscription. Paoli now saw it was high time to declare himself. He assembled his countrymen, by whom he was appointed general-in-chief and president of the council of government. At the first declaration of war between England and France, he applied to the English commanders in the Mediterranean, and, with their assistance, drove the French garrisons out of the island. Soon after, a deputation of the consulta proceeded to London to offer the crown of Corsica to the King of Great Britain. The offer was accepted, and most Corsicans expected that Paoli would have been appointed viceroy, but Sir Gilbert Elliot was named to that office. This and some subsequent disagreements made it desirable for Paoli to leave the island, in order not to give a pretence for civil dissensions. Having recommended his countrymen to remain firm in their allegiance to the British crown, as their only means of salvation, he returned to England, where he lived in retirement for several years, on a pension which the British government allowed him. He died near London, in February, 1807. A monument, with his bust and an inscription, was raised to his memory in Westminster Abbey.

The biography of Paoli has been written by Pommereul in an hostile and unfair spirit; Boswell, on the contrary, has written a kind of panegyric with his usual commonplace enthusiasm. Pompei, in his 'Etat de la Corse,' Paris, 1821, gives the best account of the particulars of Paoli's life. Botta, in his 'Storia d' Italia,' book 46, gives a copious narrative of Paoli's career in Corsica. A volume of Paoli's letters has been published, which, with his speeches and manifestoes, are his only literary remains.

PAOLO, S., or more properly S. PAULO, a town in Brazil, in 23° 33′ S. lat. and 46° 36′ W. long., about 40 miles from the coast and its harbour Santos. The town is built on a plain 2464 feet above the level of the sea, and divided from the shore by a steep descent, down which there is no carriage road, so that all the goods which are imported or exported are transported on the backs of mules. The plain of Piratininga, on which the town is built, has an undulating surface; the hills have gentle slopes, and are covered with trees, and the level tracts between them are extensive savannahs, which make excellent pasture-ground. The streets are wide, and some of them paved, and the houses have usually two floors. They are not built of bricks or stones, but of *taipa*, that is, the walls consist of two rows of posts, and the interval between is filled with earth. Some public edifices are large, as the palace of the governor, which was formerly a college of the Jesuits, that of the bishop, the convent of the Carmelites, and the cathedral and some other churches. Three bridges of stone have lately been erected over two small streams, the Tamanduatehy and Inhangabahy, which flow on the east and west of the town, and unite some distance farther down. According to a census taken in 1815, the population was 25,412, but had increased in 1820 to 30,000, and it is now stated to exceed 40,000. About one-half of the population are whites, and the other half are descendants of whites and Indian women: the latter are here called *mamelucos*. Contrary to the common practice in America, both classes of inhabitants have the same political rights, and enjoy the same consideration in society. Education is not neglected: in the college of the town the classics and philosophy are taught, and several Paulistas have been distinguished by genius and learning. Most of the inhabitants are rich landed proprietors, and occupy themselves with agriculture and the rearing of cattle. Though situated near the tropic, the elevation of the plain above the sea is too great, and its climate too cold and wet, to be favourable to the cultivation of intertropical productions. Cotton, coffee, and sugar however are cultivated to a considerable extent, though the plantations sometimes suffer from frost and protracted rains. Tobacco and maize succeed exceedingly well. All these branches of agriculture supply articles of export, to which must be added the produce of the cattle, as jerked beef, hides, horns, and tallow. They are sent to Santos, whence a great portion goes to Rio Janeiro or directly to Europe. The jerked beef goes chiefly to Pernambuco, Seara, and Maranhão; and sugar and rum are exported to Rio Grande do Sul, Monte Video, and Buenos Ayres. The imports are manufactured goods: nothing is made in the town except coarse woollen cloth for the lower classes, and very indifferent hats. Some twenty years ago government erected a manufacture of guns, in which English iron, and that of the mines of Sorocaba, situated in the province of S. Paulo, are used.

The Paulistas are distinguished, in the history of Brazil, by their enterprising spirit, and their long expeditions into the interior of South America. A small colony existed in 1527, at S. Vincente, on the coast: the inhabitants formed in 1560 a settlement at S. Paulo, which soon increased on account of the healthiness of the climate, and the friendly intercourse between the settlers and the Guayanazes, a native tribe inhabiting this country, with whom they intermarried. They soon began to explore the country farther north and west in quest of gold, and they advanced to the Laguna dos Xarayes and the present boundary-line of Bolivia. It may be said that nearly all the settlements of the Portuguese in the interior of Brazil north of 10° S. lat. owe their existence to the activity and the adventurous spirit of the Paulistas, and that but for the expeditions undertaken by them, the authority of the Portuguese would never have penetrated, as it has done, to the very centre of South America and even farther. Even when Portugal was united with Spain under one government (1580 to 1640), the Paulistas considered the Spaniards as their enemies, and checked their progress into the interior of South America by destroying their settlements on the Paraguay. They were accordingly represented by the historians of that period as living in a state of anarchy. After Portugal had re-acquired its independence, the Paulistas submitted to the viceroy of Bahia, and remained faithful subjects to the king of Portugal. They are still distinguished among the inhabitants of Brazil by their activity, spirit of enterprise, independence of character, and freedom of manners.

(Henderson's *History of Brazil*; Spix and Martius, *Reise in Brasilien*.)

PAOLO SARPI. [PAUL SARPI.]

PAPAL STATE, STATO PONTIFICIO, called also *Stato della Chiesa*, is the name given to the dominions belonging to the *See* of Rome, of which the Pope is the monarch. This state occupies the central part of Italy, stretching across the Peninsula in an oblique direction from the Mediterranean to the Adriatic. Its greatest length from north to south, from the mouth of the Po at Goro to Monte Circello, which is the most southern point, is about 260 miles: the breadth is very unequal, being about 120 miles in its southern part, along the coast of the Mediterranean, but it is hardly half that distance farther north towards the middle of its length, owing to the frontiers of Abruzzo protruding considerably to the westward. It becomes still narrower near Pesaro and Rimini, where, being straitened between the Adriatic on one side and the eastern frontier of Tuscany on the other, it is hardly 20 miles across. Farther north it becomes wider as it stretches into the plain of the Po, and it is about 50 miles, from east to west, from the Adriatic to the frontiers of Modena. The area of the Papal State has been reckoned, according to Neigebaur and other German writers, at 17,822 English square miles. Calindri (*Saggio Statistico*) reckons it at 18,117 square Roman[*] miles. Of these, 7000 square miles consist of plains, about 4000 square miles consist of cultivated hills, 4600 are highlands covered with pasture or planted with timber-trees, and 2500 are mountains mostly rocky and barren.

The Papal State consists, geographically speaking, of three great divisions: 1. The northern provinces stretch from the Tuscan Apennines to the Po and the Adriatic, the ground sloping to the north and north-east, and merging into the wide plain of Lombardy. These provinces are the four legations of Bologna, Ferrara, Ravenna, and Forli, and have a population of about 950,000 inhabitants. This part of the country resembles the rest of north Italy in its climate and soil, and belongs almost entirely to the basin of the Po. [BOLOGNA; FERRARA.] In antient times it was out of the limits of Italia Proper, and formed part of Cisalpine Gaul; and even now the inhabitants, in their character and habits, rather resemble their Lombard neighbours than their fellow-subjects of the rest of the Papal State, from whom they are divided by several offsets of the Apennines, which approach close to the Adriatic coast in the neighbourhood of Rimini, where the Rubicon constituted the political boundary of Italia Proper in the time of the Roman republic. South of this point begins the second geographical division of the Papal State. 2. This, which may be called the eastern division, extends from Rimini to the Tronto on the frontiers of Naples, a length of 110 miles along the coast of the Adriatic. It is bounded to the west and south by the central ridge of the Apennines, which separates it from the southern part of the Papal State, or the basin of the Tiber. This eastern division lies almost entirely on the eastern slope of the Apennines, the numerous offsets of which run in parallel ridges in a north-east direction from the central chain to the Adriatic coast, forming many transverse valleys watered by streams or torrents which have a short but rapid course. The distance from the central ridge or watershed to the Adriatic varies from 30 to 40 miles. The country is fertile and healthy, and is inhabited by an industrious and lively race of people. It is generally designated by the name of the Marches, and the people are called 'Marchigiani' [MARCA DI ANCONA]; but it is administratively divided into the provinces of Pesaro e Urbino, Ancona, Macerata, and Fermo e Ascoli, the united population of which amounts to about 800,000 inhabitants. 3. The third or southern division of the Papal State, the largest in extent, though not so densely peopled as the other two, is the most important, because it contains the metropolis, and includes the classical land of Latium and the other provinces which formed the early territory of antient Rome. It extends south of the central ridge of the Apennines as far as the coast of the Mediterranean, being bounded on the west by Tuscany and by the kingdom of Naples on the east. This fine region comprises the antient territories of Umbria, the Sabini, old Latium, and the western part of Etruria, and is now divided into the administrative provinces of Perugia, Spoleto e Rieti, Viterbo, Frosinone, and Rome, with a population of about 900,000 inhabitants. Its length from north to south, from the Apennines above Gubbio, the antient Iguvium, to the shore of the Mediterranean at Mount Circello, is 150 miles, and its greatest breadth, from the small river Pescia, on the boundary of Tuscany, to Terracina, on the borders of Naples, is 120 miles. This extensive country is divided, with respect to its climate and productions, into two parts—the high lands and the valleys of the Apennines, including the valley of the upper Tiber, which are well cultivated and generally healthy; and the low lands of the Campagna and some other spots around the lakes of Perugia, Bolsena, and Bracciano, which are unwholesome and thinly inhabited. [CAMPAGNA DI ROMA.] There are few regions in Italy finer than the broad valley of Foligno and Spoleto, the valley of Terni, the elevated plain of Rieti, and the rich territory around Perugia.

The central ridge of the Apennines, which forms the watershed between the Adriatic and the Mediterranean, enters the Papal State from Tuscany north of Cittá di Castello, and runs in a south-south-east direction, forming for a while the eastern boundary of the valley of the Upper Tiber, and dividing the waters of the Metaurus, which run into the Adriatic, from those of the Chiascio, an affluent of the Tiber. The road from Rome to Pesaro by Nocera passes over this part of the ridge, between Gualdo and Cagli. Near the latter town is a defile cut through the rock by the antient Romans, now called Il Furlo. East of Nocera the ridge becomes more lofty between the sources of the Esino and Potenza, which run to the Adriatic, and those of the Topino, which flows southwards by Foligno into the Tiber. Farther south-east there is a depression, through which passes the high road from Rome to Loreto and Ancona. This mountain-pass, which lies between Serravalle and Foligno, is known by the name of the pass of Colfiorito. South of this pass the Apennines form a lofty group extending to the eastward, and known by the name of Monte Sibilla, the Mons Tetricus of the antients, which is 7200 feet high, and is the highest summit in the Papal State: it divides the waters of the Tronto, which flows to the Adriatic, from those of the Nera, which flows south-west into the Tiber. The ridge then joins the mountains of Abruzzo in the kingdom of Naples east of Norcia. Two offsets detach themselves from the main ridge above the sources of the Nera, and run south, skirting the two banks of that river as far as its junction with the Tiber. The more eastern offset is intersected by the Velino, which makes its way through it by a fine waterfall not far from Terni. The whole fall of the Velino, from the level of the water above the cascade to its confluence with the Nera through a succession of rapids, is above 1000 feet. The country eastward of the Nera consists of high lands, which adjoin those of Abruzzo, and are a most interesting region, but seldom visited by travellers. [RIETI.]

The southern division of the Papal State chiefly consists of the basin of the Tiber. This river rises at the foot of Monte delle Balze in a deep dell of the Tuscan Apennines, and not, as is often erroneously stated, in the mountain of Falterona near the sources of the Arno, from which those of the Tiber are about 20 miles distant to the east-south-east, the lofty ridge Dell' Alvernia intervening between the two rivers. The Savio, which flows by Cesena to the Adriatic, has its sources on the north side of the same mountain on the south slope of which are those of the Tiber. The Tiber rises from two springs of limpid water in a wood of beech-trees, and, being swelled by mountain streams, flows in a south direction through a narrow valley called Val Tiberina, between the mountains Dell' Alvernia and Catenaia on the west and the Alpe della Luna on the east, which last forms part of the main or central ridge of the Apennines, and separates the waters of the Tiber from those of the Metaurus. The river passes by the towns of Pieve Santo Stefano and Borgo San Sepolcro, after which it receives the river Sovara, and soon after leaves the Tuscan territory and enters the province of Perugia in the Papal State. (Benci, *Lettere sul Casentino e la Val Tiberina*, in the *Antologia* of Florence, Nos. 10 and 11.) It then flows by the walls of Cittá di Castello, and after a rapid course of about 50 miles from its sources it reaches the foot of the hill upon which stands the town of Perugia. it then flows through a fertile valley, receiving on its left bank the united waters of the Chiascio from the mountains of Gubbio, the Topino from Foligno, and the Maroggia, joined by the Clitumnus, from the valley of Spoleto; and lower down, on its right bank, the river Nestore, which comes from Cittá della Pieve on the borders of Tuscany. The river then enters a narrow gorge between two rocky ridges, on one of which stands the town of Todi, the antient Tudertum or Tutere, a city of the Umbri and afterwards of the Etruscans, which is more than 1000 feet above the sea. Part of the walls of Todi is of Etruscan construction, and in its territory has been found a vast quantity of Etruscan medals and other antiquities. (Cæsius, *Elogium in priscum Tuderti Decorem*, 4to., 1632; Lauro,

---

[*] Seventy-four Roman miles make one degree of latitude.

Todi, antichissima Città dell' Umbria, 1635.) The bottom of the river here falls about 2 feet in every 1000 feet, and the bed being confined and partly encumbered by stones and gravel brought down from the mountains, the waters rise in flood times as high as 24 feet, but the river is very shallow in the dry season. The navigation of the river, which, from Perugia to Todi, is carried on merely by rafts, becomes here totally interrupted. The Tiber, after receiving the Naia and other mountain-streams, issues out of the gorge at the rapids called 'Passo del Forello,' after which it enters a broad valley. It receives near Orvieto the river Paglia from the mountains of Tuscany, which is swollen by the waters of part of the Chiana. [Chiana.] The river now assumes a more regular and less rapid course, flowing in a deep bed and inclining to the south-west. It receives the Vezza from Montefiascone, and lower down the Nera, the largest of its affluents, near the town of Orta. The whole course of the Tiber, from its sources to the confluence of the Nera, is about 110 miles. From this point the regular navigation of the Tiber begins: boats of various sizes, some of which are 80 feet long and of 80 tons burden, carry to Rome wine, corn, charcoal, wood, and other produce of the upper country. In ascending the river, they are towed up by buffaloes.

The Nera, the ancient Nar, a considerable river, rises in the high Apennines above Norcia, and is increased by the waters of part of the Abruzzo and of the Papal province of Rieti, through its affluents the Corno, Velino, Salto, and Turano. Flowing through a deep valley between the Sabine Mountains on one side and the mountains of Spoleto on the other, which divide it from the valley of the Clitumnus, it passes the towns of Terni and Narni, and, after a course of about 70 miles, enters the Tiber near Orta.

After the confluence of the Nera, the Tiber flows through a valley between the Sabine Mountains on one side and the offsets of Mount Cimino on the other: it receives on its right bank the united waters of the Treia from Civita Castellana and the Ricano, which is the outlet of the small lake of Vico, after which the valley becomes contracted between Mount Soracte on the west and the mountains of Poggio Mirteto on the east. After this contraction, it opens into the wide undulating plain of the Campagna. Three miles above Rome the Tiber receives the Anio, or Teverone, from the eastern Apennines, which has a course of above 60 miles. The course of the Tiber, from the confluence of the Nera to Rome, is about 70 miles, in which distance the width of its bed varies from 160 to 300 feet, the depth from 8 to 22 feet, and the fall is about one foot in every 2000 feet. Boats are three days in coming down from Orta to Rome, but in summer the navigation is often interrupted, owing to the shallowness of the water in several places. Within the walls of Rome the Tiber is about 300 feet wide and from 12 to 18 feet in depth. The river is never fordable in or near Rome. During heavy rains and floods the waters sometimes have risen more than 30 feet above their ordinary level, overflowing the lower parts of the city, and occasioning considerable mischief. The maritime navigation begins below Rome: the Tiber, after being confined by the quays and buildings of the town, spreads out to the width of 300 feet, until its bifurcation at Capo due Rami, a distance of 17 miles from Rome. From thence one branch of the river runs south-west into the sea by Ostia, a distance of about 5 miles, but is rendered useless for purposes of navigation by the accumulation of alluvium and sand at the mouth. [Ostia.] The other branch, which was widened by Trajan, and has been improved at various times by the popes, in order to keep open the communication between Rome and the sea, runs for about 4 miles, until it enters the sea at Fiumicino, where the entrance is secured by two long piers consisting of wooden palings and fascines. In winter time vessels of from 150 to 190 tons, besides smaller ones, ascend the river to Rome, but in summer there is often not more than 9 or 10 feet of water on the bar, and only boats of 40 or 50 tons can ascend to Rome. There is no perceptible tide in this part of the Mediterranean, and the vessels are towed up by buffaloes. (*Carta Geografica dello Stato della Chiesa*, by Le Maire and Boscovich, dedicated to Benedict XIV.; Bacci, *Del Tevere Libri IV.*, Roma, 1558-99; Martinelli, *Descrizione di diversi Ponti sopra li Fiumi Nera e Tevere*, &c., 1676; Tournon, *Études statistiques sur Rome*, book v.)

The basin of the Tiber below Rome is bounded on one side by the Alban Mount, and on the other by the offsets of Mount Cimino, which surround the basin of the lake of Bracciano, the waters of which enter the sea by the river Arrone. The Tiber, below Rome, receives only some small streams, the principal of which is the Galera, on its right bank. The basins of the lakes of Bracciano and Bolsena, which are separate from that of the Tiber, constitute, together with the basin of the river Fiora, near the Tuscan border, the greater part of the province of Viterbo, called also Patrimonio di S. Pietro. [Viterbo, Province of.] In the opposite or south-east direction, the Alban Mount separates the basin of the Tiber from that of the Pomptine marshes; and farther north the mountains of Palestrina separate the basin of the Tiber from that of the Liris, of which the Sacco is an affluent. [Palestrina.] With these exceptions, the whole southern division of the Papal State, from the central Apennines to the sea, is included in the basin of the Tiber, which also comprises a considerable part of Abruzzo, the waters of which country run by the Corno, Velino, Salto, Turano, and Anio, into the Tiber, and also that part of Tuscany in which the Tiber has its source, and another part farther south, near Radicofani and Chiusi, which is drained by the rivers Paglia and Chiana. The whole basin of the Tiber may include a surface of rather more than 10,000 square miles. The length of the river's course, with its windings, is about 260 miles. The Tiber is the largest and most important river of the peninsular part of Italy. The waters of the Tiber from Perugia downwards to the sea are muddy and yellowish, a peculiarity which is expressed by the epithet 'flavus' by the Roman poets. The current as it enters the Mediterranean retains its colour for a considerable distance from the shore, and contrasts with the generally blue tinge of the sea-water, with which it does not mix for some miles.

The Papal State is now divided for administrative purposes into fourteen provinces, namely, ROMA (COMARCA DI); VITERBO; FROSINONE; SPOLETO; PERUGIA; MACERATA; FERMO; ANCONA (MARCA DI); PESARO E URBINO; FORLI; BOLOGNA; RAVENNA; FERRARA; BENEVENTO. The population of the whole, according to an official report published by the government in 1833, was 2,742,000 inhabitants. The annual increase of the population appears to be at the rate of 4½ per 1000, which is considerably lower than in the kingdom of Naples, in Tuscany, and other Italian states. (Serristori, *Statistica d' Italia*.) The population is Roman Catholic, with the exception of about 10,000 Jews, who are distributed in Rome, Ancona, Sinigaglia, Pesaro, Urbino, Ferrara, Lugo, and one or two more towns. The provinces, with the exception of that of Rome, are styled Delegazioni; and the representative of the sovereign, who is at the head of the administration, is styled delegate, and is always a church dignitary. If a cardinal, he is styled legate, and the province assumes the name of Legazione. The delegate or legate is assisted by a council, composed of four laymen, appointed by the pope. There is also in every province a provincial council for local and financial affairs, which assembles for a fortnight once a year under the presidency of the delegate or legate. For this purpose the communes appoint electors, who assemble at the head-town of their respective districts, and there choose the deputies to the council. One-third of the council is changed every two years. Every delegation or province is divided into districts, and every district into communes. Each commune consists of a town or large village, with the territory and hamlets belonging to it. The communes vary greatly in population; from 1000 to 12,000 or 14,000. At the head of each district is a governor, appointed by the pope, who is also judge in the first instance, and is subordinate to the delegate in his administrative but not in his judicial capacity. Every commune has a council, consisting of forty-eight members in the head towns, of thirty-six or twenty-four in the smaller towns, and of eighteen in villages which do not contain more than 1000 inhabitants.

The members are taken in equal proportions from two classes, nobles and citizens or farmers. The office of communal councilman is for life and hereditary. The councils deliberate upon the affairs of their respective communes, and make out, in August every year, the 'tabella di prevenzione,' or budget, in which are specified the probable expenditure of the following year and the means for meeting it, including additional local taxes if required. This 'tabella' is forwarded to the delegate, who examines it, and then forwards it to Rome, where the board called 'Congregazione del Buon Governo' approves or modifies it. The tabella is then returned to the communes, who publish it, upon which it becomes law, and no magistrate can depart from its provisions. The communal council appoints yearly, by a majority of votes, the local magistrates, namely, the gonfaloniere, and six, four, or two elders, according to the size and population of the commune, subject however to the approbation of the delegate. The gonfaloniere, who must be chosen from the class of the nobility, is changed every year, and the elders every two years. The communal council appoints likewise all the officers and other servants of the commune, the secretary, the communal attorney, the receiver, the surgeon and apothecary (who for a fixed salary is obliged to attend the poor inhabitants gratis), the schoolmaster, the local police, &c. In the month of February the council examines the accounts of the preceding year, and transmits them to the delegate. The councils are always presided over by the gonfaloniere or by the governor in the head town of a district, who has a vote. The former baronial jurisdictions, privileges, and immunities have been abolished. (*Moto proprio di S. S. Leone XII. sull' Amministrazione pubblica*, &c., 5 October, 1824.) 'This system of municipal administration,' observes Count Tournon, who was prefect of Rome during Napoleon's usurpation, 'will perhaps surprise those who imagine that in the Papal State everything is left to the will or caprice of the sovereign. Abuses of power are common, no doubt, but the written law is more favourable to the liberties of the people than is commonly supposed.' (*Etudes statistiques sur Rome*, vol. ii., pp. 41, 72.) The communal councils are in fact more independent of the central authority than those of France. The common lands were sold by Pius VII. in order to supply the urgent wants and exactions of the French military. The ordinary revenue of the communes is now derived from taxes levied upon provisions coming to market, like the French octroi; and the extraordinary deficiency is made up by a capitation tax and a tax upon cattle. The expenditure consists of administrative, judicial, and police salaries, the repairs of the roads, public buildings, fountains, &c., the emoluments of the communal surgeon and apothecary, schoolmaster, and preacher who comes during Lent and Advent to deliver sermons adapted to those epochs. In the larger towns there are schoolmistresses, called Maestre Pie, paid by the commune for the elementary teaching of girls. Every Sunday afternoon, the children assemble in the various churches to hear the 'dottrina,' or catechism, explained to them by the rector or his assistant, and be examined upon it. Still there is no universal system of elementary instruction enforced as in North Italy, and the proportion of illiterate people in the Papal State is much greater than in Lombardy.

The universities are those of Rome, Bologna, Perugia, Ferrara, and Macerata. There are also 21 colleges or gymnasia, four at Rome, and the others in the chief towns of provinces. Females of the higher classes are chiefly educated in convents.

With regard to the central government, it is an elective monarchy; the pope for the time being is the absolute sovereign of the state; he consults the cardinals assembled either in special congregations, or, in cases of great importance, in general consistory, but he is not bound by their opinion. His two principal ministers are the cardinal secretary of state and the cardinal Camerlengo. The former superintends the department of foreign affairs and the home department; he is appointed by the reigning sovereign, at whose death his office expires. The cardinal Camerlengo is the finance minister, and is appointed for life; he has under him a treasurer. The governor of Rome is under the authority of the secretary of state, but is vested with great discretionary powers as to the police of the capital and its territory. The congregation or board called 'Sacra Consulta,' consisting of cardinals and prelates, superintends the administration of the provinces, and is also a court of appeal for criminal matters. A prelate and three general officers form a board for military affairs. The Papal State is divided into three military divisions, with an inspector at the head of each; the head-quarters are Rome, Ancona, and Bologna. The army consists of ten battalions of native infantry, 7200 in all; two Swiss regiments of two battalions each, 4840; native cavalry 1050 men, and artillery 1000; two companies of Swiss artillery, 250; the carabineers, who have the charge of the police like the French gendarmes, 2500 strong; a corps of riflemen, 1000; and 1500 custom-house guards: total, 18,740 men. There are also several battalions of militia and volunteers.

The judicial department consists of a judge, called Prætor, for civil matters in the head town of every province; two courts of appeal, one at Rome and the other at Bologna; and a Court of Cassation, called La Segnatura, which sits at Rome. The ecclesiastical courts in each diocese judge of suits between clerical persons, and also between laymen who agree to bring their disputes before these courts. For criminal matters, there is a collegial court in every province, presided over by the delegate; and two courts of appeal, one at Rome and the other at Bologna. When an appeal is laid before the sovereign, the 'Uditor Santissimo,' a prelate of the first class, judges finally of the case. The tribunal of the Inquisition and other ecclesiastical courts continue to take cognizance of matters within their respective jurisdictions. According to a table of criminals who were suffering punishment at the end of the year 1832, given by Serristori, there were 580 tried for murder or homicide, 277 for wounds inflicted, 340 for robbery, 215 for thefts, 811 for petty larceny, 91 for rape, 76 for political crimes, 66 for correctional or police matters, 7 for coining, and 244 for other crimes not defined; in all, 2708. It appears from this report that offences against the person still bear a very high proportion in the calendar of the Papal State. The penalties are imprisonment and hard labour either for life or for a term of years. Capital executions are resorted to only in very aggravated cases. Torture has been finally abolished. Tribunals of commerce are established at Rome, Bologna, Ancona, and some other of the principal towns.

The revenue amounts to about nine millions of Roman scudi (the scudo is worth 4*s.* 5*d.* sterling), a sum considerably exceeded by the expenditure for several years past, the deficit having been made up by additional loans and issues of exchequer bills. The interest of the funded debt is 2,547,000 scudi; the collection of the revenue costs about one million and a half; the military establishment costs about two millions; the judicial establishment, nearly one million; the administration, half a million; the civil list of the pope and his court, 265,000 scudi; payments to the cardinals, 122,000; public works, roads, &c., 540,000; public instruction, 108,000; charitable establishments, 267,000. The principal sources of the revenue are the land-tax, which amounts to nearly two millions of scudi; customs, one and a half million; excise, including the 'macinato,' or duty on flour, nearly two millions; monopoly of salt and tobacco, 1,200,000 scudi; stamps and registry duty, 578,000; post-office, 288,000; lottery, 896,000.

The population of the Papal State is chiefly agricultural A great extent of land is used for pasture. The exports are cattle, wool, cheese, lambskins, tallow, hemp, oil, some silk, vitriol, sulphur, pozzolana, potash, and cream of tartar. The salt-pans of Cervia and Comacchio, near the Adriatic coast, supply most of the salt for the consumption of the country Vitriol is found near Viterbo, alum at La Tolfa near Civitavecchia, sulphur near Rimini, and coal near Pesaro and at Sogliano near Forli. Wood and charcoal are the only fuel used.

The manufactures of the Papal State are of more importance than is generally supposed. Court Tournon, thirty years since, remarked on the dogmatic flippancy of travellers who told the world that 'the sale of relics and indulgences constituted the whole commerce of Rome, and the manufacture of beads and saints' images the only industry of the people.' (*Etudes Statistiques sur Rome*, b. iii.) But since Tournon's time, manufacturing industry has considerably increased. One of the principal and oldest branches is that of woollen cloths, which are made in various towns of the state, and chiefly supply the internal consumption, especially of common or coarse cloth. The silk manufacture is on the increase at Rome and Bologna. Tanneries are established, chiefly at Ancona, Bologna, Pesaro, and Sinigaglia. The manufacture of paper is also on the increase, as well as that of hats. Manufactories of soap are about forty in number, but the principal manufactory is at Pontelagoscuro, near Ferrara. There are iron-smelting furnaces at Bracciano, Canino, and Conca, and iron-works in various other places. There are glass-works in several towns, and plate-glass is made at Poggio Mirteto. Two cotton manufactories have been established at Rome, but they do not seem to thrive. Cables and rope are made in the northern provinces, and exported to Greece and the Ionian Islands. The other manufactures are wax candles, to a considerable amount, chiefly for the use of the churches; catgut, which is in great repute, and liquorice, of which there is a manufactory at Grottamare, near Fermo, as well as an extensive sugar-refinery at the same place. Serristori (*Statistica d'Italia*) gives a list of all the manufactures of the Papal State. The annual exports are stated at above five millions of scudi, not including the works of art and antiquity, sculptures, paintings, models, mosaic, &c., which form another considerable branch of export, the value of which is not ascertained, as almost every traveller who visits Rome carries away with him some articles of the kind. The imports are reckoned, according to the custom-house returns, at nearly seven millions of scudi; they consist chiefly of tobacco for the government manufactory, from Hungary, Albania, and Brazil; raisins and other dried fruit from Naples and Sicily; colonial produce from England and France; salt fish, to the amount of nearly nine millions of pounds weight, chiefly from England; iron from Elba; lead from England, besides manufactures of fine cloth, silks, cottons, hardware, and articles of luxury from France and England.

The maritime trade of the Papal State is carried on chiefly by foreigners. This is the branch of industry most neglected by the natives of the Papal State. Even the coasting-trade and the fishing along the greater part of the coast are carried on in great measure by foreign boats. The Neapolitans fish all along the Mediterranean coast, and the Venetians along that of the Adriatic, as far as Cesenatico; the native boats fish only along the coast of the Marches from Rimini to the Tronto. The Neapolitans supply Rome with fish, which is taken on its own coast. The consumption of fish is very great, owing to the number of meagre days in Lent, and at other times, which are ordered by the church of Rome, and enforced by the civil laws of the country. It is calculated that the annual consumption of fresh fish throughout the Papal State amounts to thirty millions of pounds weight. Austrian vessels, to the number of 800, carry on most of the trade in the Adriatic ports of the state; and Neapolitan, Genoese, and Tuscan vessels or boats, in those of the Mediterranean. On the Adriatic coast the natives of the Papal State possess about 230 vessels, chiefly small craft, and about 350 fishing-boats. The Papal navy consists of an armed schooner, stationed at Civitavecchia, and a few custom-house boats at Civitavecchia and Ancona.

According to Calindri (*Saggio Geografico Statistico dello Stato Pontificio*) the number of monks, friars, and other clergy living in communities in the Papal State amounts to about 10,440, distributed among fifty various monastic orders or congregations; that of the secular clergy, to 34,660; and that of the nuns and other women living in cloisters, is 8200: making in all 53,300 individuals of both sexes devoted to religious celibacy, which is about 1 for every 52 of the whole population. The number of adult lay persons of both sexes living in voluntary celibacy (not including those already mentioned) is about half a million, 89,000 in a state of widowhood, whilst that of married persons is 913,800. The rest of the population consists of children of both sexes. There are in the whole state 100 towns, and 722 'terre,' or large villages having municipal councils, besides hamlets.

Savings' banks have been established of late years at Rome, Ancona, Bologna, and some other towns; an insurance company has been formed at Rome, as well as a bank, with a charter for a limited period.

Monti di Pietà have been long established at Rome and other large towns of the state. (MONT DE PIETÉ.)

The principal products of the Papal State are: 1, corn, namely wheat, barley, rye, and Indian corn, which are produced in great quantity in the northern and eastern provinces; rice is also extensively cultivated in the low grounds; 2, oil, which is made in considerable quantity, but is generally of inferior quality; the best is made in the hills of Sabina, Orvieto, and the Marches; 3, wine, of which the greater part is ordinary wine, for home consumption; some better qualities however are made in the Marches, and on the hills of Albano, Orvieto, and Montefiascone; 4, pulse and vegetables of every kind; 5, fruit, including lemons and oranges, which grow in the open fields only in the southern provinces, and chestnuts in the highlands; 6, hemp and flax, especially in the provinces near the Adriatic; 7, silk is made in the eastern provinces, especially near Fossombrone; 8, tobacco is grown also in the eastern provinces near Ancona; 9, timber and wood for fuel. The Papal State is still well provided with forests of oak, cork trees, elm, ash, and pine; among the pine trees the *Pinus pinea* is remarkable for its height and elegant appearance. The principal forests are on the sides of the Apennines, on the Mounts Cimino and Albano, on parts of the Mounts Lepini, and along the sea-coast of the Mediterranean. The fine pineta, or pine forest, near Ravenna, along the Adriatic shore, has been noticed by Byron, in 'Childe Harold,' canto iv.

The horned cattle are remarkably fine, especially in the province of Perugia and the Campagna of Rome, and also in the province of Ferrara. Calindri reckons the horned cattle at 1,238,000 head. Very good cheese and butter are made, especially in the southern provinces. The sheep are reckoned at two millions. The finest are said to be those of the province of Macerata in the Marches. Much cheese is made of ewes' as well as goats' milk. Pigs are reared in great number, especially in the Campagna. Wild boars are numerous in the Pontine Marshes. The horses are reckoned at about half a million in the whole state. The lakes and rivers abound with fish; the eels of Bolsena and Comacchio are celebrated.

Upon the whole the Papal State is very far from being poor and unproductive, as is supposed by most foreigners, and as has been carelessly stated by many travellers who have merely crossed the desolate plains of the Campagna, and have taken them as a specimen of the whole country. There is no doubt however that the country might be made more of, and that the agriculture and other branches of industry are susceptible of great improvements.

Modern History.—The origin and formation of the sovereign state called the Papal State, which is annexed to the See of Rome, is one of the most obscure and intricate subjects in the history of modern Europe. Setting aside the pretended donation of Constantine, we find that, after the fall of the Western empire and the re-conquest of Italy by Belisarius and Narses, Rome and the adjoining territory were administered by an officer called prefect, duke, or patrician, appointed by the Byzantine emperor, and subordinate to the exarch of Ravenna. Rome retained its municipal government, had its senate and assemblies of the people, and the bishop of Rome, styled 'Præsul' in some of the documents of those times, was elected by the joint votes of the clergy, the senate, and the people, but was not consecrated until the choice was confirmed by the Eastern emperor. The See of Rome enjoyed large revenues and benefices, the gifts of various emperors, besides the gifts and bequests of private persons and the alms of the pilgrims and other pious persons. During the two centuries that the Longobards occupied the greater part of Italy, they often threatened but never took Rome, and the people of that city, forsaken as it were by the Eastern emperors, accustomed themselves to look upon their bishop as their chief defender and protector. The popes, through their spiritual influence and also their personal activity, were the chief means of preserving Rome from being occupied by the Longobards, but they acted generally in concert with the exarchs of Ravenna, at whose court they kept an agent. The services rendered to Rome and to Italy in general by the popes during that period, and the true character of the dominion of the Longobards over the native Italians, have been exhibited with great fairness by Manzoni, in his 'Discorso sopra alcuni Punti della Storia Longobardica in Italia,' published at the end of his tragedy of 'Adelchi,' and in which he combats the party statements of Giannone and other writers, who, through a feeling of resentment against the subsequent encroachments of the Papal See, have misjudged and misrepresented the real state of the question between the popes and the Longobards.

The persecution of images and image worship by Leo the Isaurian, about A.D. 720, dissolved the loose bond that still attached Rome to the Eastern empire. The Romans and the Italians in general refused to submit to the edict of Leo, and after the emperor was condemned by Pope Gregory II. in the council of Rome, A.D. 726, they refused to pay the usual tribute to the Eastern empire. About the same time a conspiracy was discovered at Rome against the life of Gregory, in which Marinus, duke or imperial lieutenant of Rome, was implicated in concert with the exarch of Ravenna, and the consequence was, that the Romans would no longer acknowledge the authority of Marinus. (Anastasius, *Vita Gregorii II.*, in Muratori's 'Rerum Italic. Scriptores.') The Byzantine writer Theophanes says that the pope countenanced and encouraged this feeling in the people; but Paulus Diaconus (vi. 49) says that 'the people and the troops at Ravenna and in the Venetia resisted, all of one accord, Leo's edict against the images, and would have proclaimed another emperor, had not Pope Gregory dissuaded them from it.' Meantime Luitprand, king of the Longobards, took from the Byzantines the greater part of the exarchate and the Pentapolis, which latter corresponds to the present March of Ancona.

Rome now governed itself as an independent commonwealth, retaining the title of duchy, having its senate, its consuls, and tribunes, and forming alliances with the dukes of Benevento and Spoleto, and with King Luitprand. The pope was generally the mediator or active promoter of these transactions. As the good understanding between the Longobards and the Romans was not however of long duration, the latter at times resumed an intercourse with the court of Constantinople, and they even applied to Constantine Copronymus to send them assistance: but the Greek emperors being unable or unwilling to exert themselves in defence of Rome, the popes began to think of turning themselves for protection towards the West, where the Frankish monarchy had attained great extent and importance. Gregory III., Zacharias, and Stephen III. wrote repeatedly to Charles Martel and his successor Pepin in the name 'of the senate and the people of Rome,' who, having renounced their allegiance to the Eastern emperor, wished to place themselves under the powerful protection of the kings of the Franks. Their letters are inserted in the 'Codex Carolinus.' Stephen III., after having crowned, by means of his legate, Pepin, king of the Franks, at Soissons, A.D. 751, conferred upon him the title of Patrician of Rome, which was the appellation of the officer who used to represent the Byzantine emperor in that city. And when Astolphus, king of the Longobards, devastated the territory of Rome, Stephen wrote to Pepin, in the name 'of the Church, and of the dukes, counts, tribunes, and people of Rome,' to urge him to defend the city of which he had been appointed first magistrate. Pepin repaired to Italy with an army, and, having defeated Astolphus, obliged him not only to respect the duchy of Rome, but to give up the exarchate of Ravenna and the Pentapolis, not to the Eastern emperor, their former possessor, but 'to the Holy Church of God and the Roman republic.' Such are the words used by the historians of those times, but the text of Pepin's donation is lost. The following list of the towns included in this grant is given by Anastasius:—Ravenna, Rimini, Pesaro, Fano, Cesena, Sinigaglia, Jesi, Forlimpopoli, Forli, Montefeltro, Castel Sussubio, Acerragio, Monte di Lucaro, Cerra, Castel S. Mariano, Bobbio, Urbino, Cagli, Luceolo, Gubbio, and Comacchio. Astolphus sent the keys of these towns to be deposited on the altar of St. Peter at Rome, but he did not give up the towns, and the possession of the Church and the Roman republic was merely nominal. The popes complained repeatedly in their letters of the nonfulfilment of the act of donation. Desiderius, the successor of Astolphus, at one time gave up some if not all of those towns to be administered, not by the Romans, but by the archbishop of Ravenna, who was considered as standing in the place of the former exarchs. (Agnellus, *Liber Pontificalis, in Vita Sergii Archiepisc.*, in Muratori, 'Rer. Italic. Script.' vol. ii.)

Charlemagne, urged by the entreaties of Adrian I., having come to Italy, defeated Desiderius, and overthrew the kingdom of the Longobards. He assumed the title of Patrician of the Romans, and he is stated to have confirmed his father's donation of the exarchate and Pentapolis; afterwards however we find Adrian repeatedly urging him by letters, but apparently to no purpose, 'to fulfil, for the good of his soul, what he had promised in favour of the Church and the Roman republic.' It would not seem that Charlemagne ever intended to give up the regal rights or sovereignty of those towns and territories, for he assumed the imperial authority even over Rome, by the consent of the Romans themselves, and money was struck and public acts done in his name, 'imperante Domino nostro Karolo.' But he gave to the See of Rome the rents and fees of extensive domains in the exarchate and Pentapolis and other provinces, whilst he kept the regal rights. Another act of donation by Louis the Pious, son of Charlemagne, is cited by Baronius, in which that prince gives to the See of Rome not only the Æmilia or Exarchate, and the Pentapolis, but also Sicily, Calabria, the duchy of Naples, Sardinia, and other countries which had never belonged to Louis or Charlemagne: but Pagi, Muratori, and most other critics, consider this act as apocryphal.

Under the Carlovingians Rome was an imperial city, with its municipal government and its senate; its territory or campagna was occupied by powerful nobles or barons, and the pope himself, in his temporal capacity, was the principal baron at Rome. The other provinces which now constitute the Papal State, such as Spoleto, Viterbo, Camerino, Fermo, &c., were in the possession of dukes or counts who were vassals of the crown of Italy. The popes, following the example of the great feudatories of those times, granted part of their extensive domains in subinfeudation to lay barons on military tenure, and this seems to have been the origin of the petty principalities of the Romagna. In the course of centuries, these subfeudatories, who, during the anarchy of the kingdom of Italy, had made other acquisitions of territories and towns, considered themselves and acted as independent princes, until Innocent III. and other popes subdued them by force, asserting their right not only over the domains subinfeudated by their predecessors, but over the towns and territories which the various princes had acquired by themselves or had received by grant from the emperors and kings of Italy; and the popes then put forth in support of their claims the old and never executed donations of Pepin and Charlemagne. This however did not take place till the beginning of the thirteenth century, about 400 years after Charlemagne. During this long period the emperor or king of Italy was considered as the sovereign of the whole country, and whenever he came to Rome he exercised his sovereign rights in that city as in the rest of Italy. But in his absence, the duchy of Rome, as it was still called, was often in a state of anarchy, its government fluctuating between a democracy and the power of the great feudal families. Some of these families influenced the election of the popes, as was the case in the tenth century, when Theodora, her daughter Marozia, and Alberic, the son of Marozia, were all-powerful at Rome. At last Otho of Saxony came to re-assert the imperial authority over Rome and the rest of Italy. [Otho I.] Otho II., in a diploma which he gave to the republic of Venice at a general diet held at Verona, A.D. 983, enumerated the towns of the Exarchate and Pentapolis as subject to the kingdom of Italy. [Otho II.] Under his successor Otho III., Crescentius, a Roman noble, being appointed consul by the people of Rome, attempted to free that city and its duchy from the dominion of the German emperors, and to replace them under the nominal allegiance of the emperors of the East, who, being distant and weak, would have left the Romans in a state of comparative independence. He however failed, and was beheaded by order of Otho III. John, the son of Crescentius, about the year 1010, restored in Rome the republican form of government, with a senate of twelve senators, two consuls, assemblies of the people, and a prefect to administer justice. (Ditmarus, b. vi.; Mabillon, *Annales Benedict.*, ad anno 1011.) The temporal power of the popes in those times was very little, being restrained on one side by the republican spirit of the people, and on the other by the imperial power, which retained the ascendency whenever the emperor visited Rome. But although nearly destitute of temporal power in Rome and the Roman territory, the popes found means through their spiritual influence to establish the authority of the see of Rome over larger and finer regions. Leo IX. granted to the Norman adventurers who had conquered Apulia, the investiture of that county as well as of Calabria and Sicily in the name of St. Peter, to be held as a fief of the Roman see, to which the crowns of Sicily and Naples have continued till within our own times to pay tribute as vassals.

The great contest of Gregory VII. against the emperor Henry IV. had for its object to exalt the authority of the church over the civil power in general, and to assert at the same time the supremacy of the see of Rome over all other sees. But during this struggle an important addition was made to the temporal claims of the see of Rome by the donation of the Countess Matilda, the staunch supporter of the papal power. This lady added to her paternal fiefs in the Modenese, Parmesan, and Mantuan territories, the rich succession of Godfrey, marquis of Tuscany, second husband of her mother Beatrix. (Florentini, *Memorie della gran Contessa Matilda*; Donizo, *Vita Comitessæ Matildæ*.) She twice made donation of her territories, first to Gregory VII. and afterwards to Pascal II., which last is in her will dated A.D. 1102. But Matilda, as a vassal of the empire, could not alienate her feudal rights, but merely her allodial property, and the words of her will seem to bear the latter meaning, 'omnia bona sua jure proprietario.' (Muratori, *Rer. Ital.*, vol. v., at the end of Donizo's *Life of the Countess*.) However, Henry V., in 1116, the year after Matilda's decease, settled the question by taking possession of the whole of her property. But Matilda's donation continued long after to furnish to the see of Rome claims over a considerable part of northern and central Italy.

Innocent III. was the first pope who really formed a Papal temporal State. He found the imperial power asserted over all Italy by Henry VI., in his double capacity of king of Lombardy and king of Sicily. The emperor had distributed the domains of Matilda as fiefs among his generals. His great seneschal Marcovald was duke of Romagna and marquis of Ancona; Philip, duke of Suabia, was marquis of Tuscany; and Conrad of Suabia, duke of Spoleto. But after the death of Henry in 1197, and of his wife Constance in the following year, their infant son Frederic was left to the guardianship of Innocent, who availed himself of the opportunity to assert the claims of his see founded upon the donations of Pepin and Charlemagne and of Matilda. He knew that the German feudatories had abused their power, and that their subjects were ripe for change. He sent two cardinals to take possession of Spoleto and the Marches, and the towns of those provinces willingly opened their gates to them, and swore allegiance to the see of Rome, their municipal franchises being guaranteed to them at the same time. These towns were Spoleto, Foligno, Nocera, Perugia, Gubbio, Todi, Rieti, Assisi, Città di Castello, Ancona, Fermo, Camerino, Sinigaglia, Osimo, Fano, Jesi, and Pesaro. Rome and its duchy were still governed as a republic, the democratic spirit of the people having been fanned and revived some time before by Arnaldo da Brescia. The authority of the senate had been formally acknowledged by Celestine III., Innocent's predecessor, and was determined by a charter of the pope, which is given by Muratori (*Antiquit. Ital. Dissertation.*, 42). But the people of Rome soon becoming tired of their senate, for whose authority they had fought, abolished it, and substituted, after the example of other Italian cities, a foreign elective magistrate, whom they styled 'the Senator,' and to whom they gave the powers till then enjoyed by the senate; they made him the head of the militia, and of the judicial administration; and they allotted the senatorial palace on the Capitol for his residence. This institution (with some alteration in its character) has continued at Rome to this day. The first senator was Benedetto Carissimo, who at the end of two years was replaced by Giovanni Capoccio. During their administration, the Romans took and destroyed Tusculum, subjugated the whole of Sabina and Campagna, and obliged the towns of those provinces to receive in future the magistrates which Rome should appoint. (Vitale, *Storia diplomatica dei Senatori di Roma*, Rome, 1791; Carolus Curtius, *Commentarius de Senatu Romano post tempora Reipublicæ Liberæ*.)

Innocent III. did not alter the form of the municipal institutions of Rome, but he contrived to have a senator chosen among his friends, and he dictated the form of the oath which that magistrate took to him. By this oath, which is given by Vitali, the senator bound himself 'to maintain the pontiff in possession of his see and of the regal rights which should belong to St. Peter's church; not to conspire against him so as to occasion him the loss of life or limb, but to reveal to him all conspiracies and machinations which might come unto his knowledge; and lastly to provide for the safety of the cardinals and their households in every part of Rome and its jurisdiction.' At the same time Innocent obliged the prefect of the city, who was an imperial officer, to pay allegiance to himself, and to receive from his hands a fresh investiture; and lastly he took upon himself to remove the judges and podestas of the towns of the Campagna, who had been appointed by the Roman republic, and he named others in their stead, thus appropriating to himself the sovereignty of a country which the Romans had lately conquered.

But the towns and territories thus subject to the papal see were still far from forming a compact state as it is in our days. The feudal rights of the nobles and the municipal franchises of the towns left to the sovereign little direct authority. The Papal State was not consolidated for nearly three centuries after Innocent III.

Rudolph of Habsburg, being elected emperor after a long interregnum, was entirely engrossed by German affairs, and had little time to bestow upon the kingdom of Italy, which had ever proved a troublesome appendage of the German crown, and he is said to have been ignorant of the geography of that country. Charles of Anjou, king of Sicily and Naples, was then the most powerful sovereign of Italy, and had extended his authority by various means over the north of Italy, where he had assumed the title of Imperial Vicar. Rudolph resented this usurpation, and Pope Nicholas III., interfering between the two sovereigns, induced Charles to give up Tuscany and Bologna, as well as the senatorship of Rome, which he had also obtained. At the same time the pope urged Rudolph to define by a charter the dominions of the holy see, and to separate them for ever from those dependent on the empire, and he sent to Rudolph copies of the donations or charters of former emperors. Rudolph, by letters patent dated May, 1278, recognised the States of the Church as extending from Radicofani to Ceperano, near the Liris, on the frontiers of Naples, and as including the duchy of Spoleto, the march of Ancona, the exarchate of Ravenna, the county of Bertinoro, Bologna, and some other places. At the same time, Rudolph released the people of all these places from their oath of allegiance to the empire, giving up all rights over them which might still remain in the imperial crown, and acknowledging the sovereignty of the same to belong to the see of Rome. This charter was confirmed by the electors and princes of the empire. Rudolph's letter and charter are found in Raynaldus's 'Annales' for the year 1278. This charter, important as a title, had little effect at the time. Rudolph gave up to the pope a sovereignty which was more nominal than real. Several of the towns thus ceded, as Bologna, Perugia, Ancona, had long governed themselves as republics, and were possessed of considerable territories; while others, such as Montefeltro and Bertinoro, constituted hereditary principalities, and the transfer of allegiance from the empire to the church made no alteration in their political condition. The pope sent his legate, Cardinal Latino, on a mission to Bologna and the Romagna, in order to produce a reconciliation between the Guelphs and the Ghibelines.

The removal of the papal see from Rome to Avignon, at the beginning of the fourteenth century, where it remained for seventy years, tended greatly to weaken the loose bond between it and the provinces above named. Accordingly we find during that period a number of petty princes and tyrants settled in central Italy often at war either among themselves or against the Visconti of Milan. The distant popes from Avignon sent legates with some mercenary troops to support the Guelph party, and to assert the authority of the papal see, but the towns and lords of Romagna stood their ground against them. At Rome, a man of obscure birth but endowed with eloquence and enthusiasm, a friend of Petrarch, put himself at the head of a popular movement, drove away the Colonna and other turbulent nobles, and proclaimed the republic, of which he was named tribune by popular acclamation. He re-established order, exterminated the robbers, and obliged the neighbouring barons to swear to maintain the new order of things, which he called 'the good state of Rome.' But the head of Rienzo was not proof against his sudden success; he became intoxicated with vanity and pride, disgusted the people, offended the barons, and at last the pope sent a legate to supersede him. After seven months' power Cola di Rienzo was obliged to run away from Rome, at the beginning of 1348, and, being arrested, was taken prisoner to Avignon. Innocent VI., some time after, having resolved to make a strong effort to reconquer the States of the Church, fixed upon Cardinal Gil Albornoz, a Spanish noble, who had already distinguished himself in the wars of Spain against the Moors, to command the expedition, A.D. 1353, and gave him Cola di Rienzo to assist him by his remaining influence with the Romans. Albornoz defeated Ordelaffi of Forli, Malatesta of Rimini, Vico of Viterbo, and other petty princes, and restored Romagna, the Marches, and the Campagna to the allegiance of the papal see. Cola di Rienzo, whom the cardinal had sent to Rome to second his views, was murdered there in a popular tumult, in October, 1354. [ALBORNOZ, GIL DE.]

The popes returned to fix their court at Rome in 1377, and the government of the Papal State then assumed a more regular form, occasionally interrupted however by insurrections of the people of Rome. [Eugenius IV.] A great part of the territory, especially north of the Apennines, continued in the hands of petty princes or tyrants. Alexander VI., in the year 1500, sent his son Cesare Borgia, who both by skill and treachery extirpated the tyrants of the Marches. [Borgia, Cesare.] Julius II., the successor of Alexander VI., put himself at the head of an army, conquered Romagna, Bologna, and Perugia, and from that time the Papal State acquired its present compact form. Ferrara was annexed to it in 1597 [Este, House of], the duchy of Urbino in 1632, after the death of the last duke Della Rovere without issue, and in 1650 the duchy of Castro and Ronciglione. [Farnese.]

In 1797, Bonaparte detached the four legations or provinces of Bologna, Ferrara, Ravenna, and Forli, and annexed them to the Cisalpine republic. In 1798 the French troops invaded Rome, and drove away the pope (Pius VI.). In 1801 the pope was restored to Rome and its territory, except the legations. In 1808 Napoleon detached the Marches, which he annexed to his kingdom of Italy, and in 1809 he took possession of Rome and the southern part of the Papal State, and annexed it to the French empire. In 1814 the pope was restored to his dominions. [Pius VII.]

The history of the Papal State, as connected with that of the rest of Italy, may be traced in Guicciardini, Muratori, Giannone, Sigonio, Sismondi, Botta, Bossi, and other historians of Italy. Muratori, in his 'Piena Esposizione dei Diritti Imperiali ed Estensi su Comâcchio,' has treated of the controversy concerning the various donations alleged to have been made to the Roman see. Cardinal Orsi has written 'Della Origine e del Dominio dei Romani Pontefici sopra gli Stati loro Temporali,' Rome, 1754. See also 'De la Puissance Temporelle des Papes,' Paris, 1812; and on the opposite side, in favour of the papal see, see De Maistre, 'Du Pape,' Paris, 1819.

PAPASQUIA'RO. [Mexican States.]

PAPA'VER, the name of a genus of plants of the natural family of Papaveraceæ, of which one of the species is celebrated for yielding Opium. The history of this, like that of many other cultivated plants, is little known, as well as the time when it began to be cultivated for the sake of its inspissated juice, though it was well known to the Greeks, and cultivated at very early periods on account of its seeds. (Theoph., lib. ix., cap. xiii., ed. Bodæus and Stapel, p. 1097.)

Some authors are of opinion that it is the μήκων of Dioscorides, and that the kind with black seeds was called ἀγρία, and that with white seeds ἥμερος; and that it is the juice of this plant which Hippocrates recommends under the name of ὀπὸς μήκωνος, or juice of the poppy. Pliny (xx., c. 18) uses *opium* to express the inspissated juice of the poppy. Sprengel, in his *Hist. Rei Herb.*, i., p. 176, quotes Diosc., lib. iv., c. 65, as referring to *Papaver somniferum*, and to *P. Rhœas*; but in his edition of that author (ii., p. 600) he mentions only the latter plant; hence we may infer that he conceives the former to have been unknown, as he nowhere else mentions it. We do not in this instance get the same degree of assistance as in many others from Arab authors. Opium is described by them under the name of *afeeyon*, while *apaynum* is quoted by Dr. Ainslie as its Sanscrit name. The poppy plant is described by the Arabs under the name of *Khushkhush*, while the Sanscrit is *chosa;* and the Persian and Hindee, *post*. The species of Papaver are chiefly found in European countries; but a few species extend to the Caucasus and Armenia, and one species grows in the Himalayas, though Egypt is the country where we find the earliest notice of the opium poppy. This species is now common in most parts of Europe, but having been so long cultivated, it may appear indigenous in many countries where it has only escaped from cultivation. It is, as is well known, extensively cultivated in India, but it can nowhere be seen in a wild state, as the climate is too hot to support it except for a few months in the year.

The genus Papaver has two convex deciduous sepals. Petals four. Stamens numerous. Style wanting. Stigmas four to twenty, radiating and sessile upon a disk which crowns the germen. Capsule obovate, one-celled, opening under the crown of the stigmas with short valves. Placentæ intervalvular, incomplete. Flower stalks inflexed at the apex before the flowers have expanded. The flowers of all are large and showy, but last a short time. Herbaceous plants abounding in milky juice.

The species are twenty-five in number, but few are remarkable for any useful properties. The English species are distinguished as having a rough and a smooth capsule: of the former, *P. hybridum* has an obovate globose capsule, and *P. argemone*, an elongated club-shaped capsule; of those with smooth capsules, *P. Rhoeas* and *P. dubium*, the former has a globose and the latter an oblong capsule.

Papaver somniferum, or the white poppy, is a native probably of Asia Minor, or of some part of the Persian region of botanists, but having been so long cultivated, it is found wild in many parts of Europe. The species is distinguished by its obovate or globular capsules, smooth as well as the calyx, the stem smooth and glaucous, leaves embracing the stem incised and repand, with subobtuse teeth. There are two distinct varieties, which by some botanists are considered to be distinct species: the dark, the red-flowered, and black-seeded is called by Gmelin *P. somniferum;* and the white-flowered with white seeds, *P. officinale*. The latter is characterised as having an ovate globose capsule; foramina under the stigma either none or obliterated; peduncles solitary. The former (*P. somniferum*) has globose capsules, opening by foramina under the stigma; seeds black: peduncles many. The flowers are usually red of different tints, though sometimes white. Dr. Royle states that he has seen only the white-flowered variety in the plains of India, and the red-flowered in the Himalayas, and both cultivated for the sake of the opium.

The poppy is cultivated in many parts of Europe on account of its seeds, which yield a bland oil much esteemed in France; and in this country chiefly on account of the capsules, which are used medicinally. It is extensively cultivated in Turkey and Asia Minor, Egypt, Persia, and India, on account of its inspissated juice, so well known as opium, though this is occasionally prepared also in Europe.

The cultivation of the poppy is very simple, though the weeding requires care, and the plants must not be crowded too much together. They are carefully watered and manured, the watering being more copious as the period of flowering approaches, and until the capsules are half grown.

In India the cultivation takes place in the cold weather, that is, during the winter of Europe. The collection of opium is commenced very soon after the flowers fall, as the capsules rapidly enlarge. The people go into the fields after sunset with small knives, usually with four crooked blades, with which they make either longitudinal or transverse incisions, and return in the morning to scrape off the opium which may have exuded, generally about one grain from each quadruple incision. But the quantity varies according to the soil, the cultivation, and the due management of the irrigation, as well as the quantity of dew deposited. When the wind is dry, or cloudiness prevents the formation of dew, the scarifications dry up, and little opium is exuded. When the dew is copious, it washes out the wounds in the capsule, and thus facilitates the running off of the milky juice. When the dew is moderate, the milk thickens in irregular tears, which are sometimes, as in a dry climate, allowed to adhere together, and dry in this state, forming the grain of opium. But in India the whole of the day's collection is rubbed together in a mortar or similar vessel, for the purpose of breaking down the grain so as to reduce the whole to a homogeneous semi-fluid mass, which should be dried as quickly as possible in the shade, and turned over very frequently.

Samples of all the opium brought for sale to the East India Company's opium factories are submitted to a steam drying process, by which the quantity of fluid in each is easily ascertained, and found often to amount to 30 per cent. These two methods of drying opium explain the accounts of different writers and travellers. Guibourt finds that Dioscorides, Kæmpfer, and M. Texier describe the opium as being pounded and mixed together, while Olivier and Belon describe it as being simply dried. The latter indeed describes opium as formed by the assemblage of the small tears gathered on the capsules. These two modes of preparation may be recognised in the opiums of commerce.

PAPA'VER. OPIUM, *Medical Properties of.*—The juice of the unripe capsule or fruit of the *Papaver somniferum* seems to have been used on account of its narcotic powers from a very early period, first in the East, of which it is a native, and afterwards in the West.

As to the two varieties of the *P. somniferum*, called *P. S. album*, in which the seeds are white, and the openings under the stigmata obliterated, and *P. S. nigrum*, in which the beds are blackish-grey, and the openings under the stigmas yellow, some differences are found in the relative proportion of some of the chemical constituents of the opium procured from them; but the *P. S. album* (*Papaver officinale*, Gmelin) is the kind chiefly cultivated in Persia and India.

'The first sophistication which the juice receives is that practised by the peasants who collect it, and who lightly scrape the epidermis from the shell to augment the weight. This operation adds about one twelfth of foreign matter. Thus collected, opium has the form of a glutinous and granular jelly. It is deposited in small earthen vessels, and beat up with saliva. On inquiring why water was not employed in the place of saliva, the answer was, that water caused it to spoil. It is afterwards enveloped in dry leaves, and in this state it is sold. The seeds of those poppies which have yielded opium are equally good for sowing the following year.' Such is the account by M. Ch. Texier, of the plan in Asia Minor. In India the juice is mixed with oil obtained from the seed of the poppy, to hinder the rapid drying of the juice. The produce of the first incisions is of a light yellow colour; the others are fainter in odour and darker coloured. In general all these gatherings are mixed together, and sent to market in small baskets. The quantity obtained varies not only with the soil and mode of cultivation, but also with the season and the time of collecting. In wet gloomy seasons not only is the quantity less, but it does not keep well; in such a case the proportion of morphia is also less. The quantity of morphia depends likewise very much on the time of gathering: if the harvest be postponed till the capsules begin to turn yellow and hard, it is greatly deficient; and by the time the capsules are mature and the seeds ripe, it has entirely disappeared. It is not, as in the case of many other vegetable alkaloids, transferred to the seeds, as they are altogether devoid of any narcotic principle, the oil which is obtained from them being bland and wholesome, and abundantly used as food; even the seeds themselves are freely eaten by birds, to which they are given (from the black variety), under the name of maw-seeds.

Several varieties of opium are met with in commerce, which may be noticed here in the order of their reputed excellence, the quantity of morphia contained in each being taken as the criterion.

1. Smyrna or Levant opium, which Mr. Pereira considers synonymous with Turkey opium; though German pharmacologists deem Turkey and Egyptian opium to be synonymous. (Th. Martius, *Pharmakognosie*.) 'It occurs in irregular roundish or flattened masses of various sizes, rarely exceeding two pounds in weight, enveloped in leaves, and intermixed with the reddish triangular capsules of several species of Rumex, such as R. orientalis, R. Patientia (which are employed to prevent the masses adhering to each other while the opium is soft). When first imported, the masses are soft, and of a reddish-brown colour; but by keeping they become hard and blackish; and on this account it is termed by the French opium noir. Its consistence is soft, at least of the interior, even when the exterior is very hard. Its fracture is waxy; the taste bitter, acrid, and persistent.'

2. 'Constantinople opium. Of this there are two sorts: one in large irregular cakes, which are flattened, like the Smyrna opium, and of very good quality; the other is in small flattened regular cakes, of a lenticular form, from 2 to 2½ inches in diameter, and covered with a poppy-leaf, the midrib of which divides the disk into two parts. It has an odour similar to the preceding kind, but more feeble; at first it is reddish both without and within, hence called by the French *opium rouge*; it however blackens and dries in the air, but never becomes so hard as Smyrna or Egyptian opium, than which it is more mucilaginous.' Th. Martius is of opinion that it is a manufactured article, prepared at Constantinople, out of Smyrna opium, by the addition of gum. It is a common article of German but rarely of English commerce. It is never covered with the Rumex capsules as the Smyrna opium.

3. *Egyptian* or *Alexandrian opium* 'occurs in round flattened cakes of about three inches in diameter, covered externally with the vestiges of the same leaf, which are in too mutilated a state to be determined. It is distinguished from the preceding varieties by its reddish colour, analogous to succotrine or hepatic aloes, which does not by time or exposure to the air become darker; the odour is fainter and somewhat musty. Though the cakes are of all the sorts much the hardest, so that a blow with a hammer will cause one to split into fragments, yet by exposure to the air it becomes soft.

4. 'Trebizond or Persian opium occurs in the form of cylindrical sticks, which by pressure have become somewhat angular. Their length is about six inches, their diameter about six lines. Each one is enveloped in a smooth glossy paper and tied with cotton. The colour of the opium is similar to that of succotrine aloes. It possesses a stronger odour than the Egyptian kind, but fainter than that of Smyrna, united with a musty one. The taste is intensely bitter.'

5. Indian opium, of which there are several varieties as already described. [Opium Trade.]

6. English opium 'is in flat cakes, enveloped in leaves. It resembles the Egyptian more than any other kind; its colour is that of hepatic aloes, with a moderately strong opiate odour.'

Before offering a summary of the points of difference, in chemical composition and other respects, of these various sorts, it is necessary to enumerate the general constituents of opium:—1, morphia; 2, codeia; 3, paramorphia or thebaine; 4, pseudomorphia; 5, narcotina or opianum; 6, narceine; 7, meconine; 8, meconic acid; 9, an oily acid; 10, gum; 11, resin; 12, extractive; 13, a fixed oil; 14, caoutchouc; 15, an odorous principle; 16, ligneous matter with inorganic salts, such as sulphate of lime and potass, &c. There are also various accidental but more intentional impurities, such as sand, of which even the best Smyrna opium contains a large portion; 10 ounces of opium frequently containing 10 drachms of stones and gravel. In the interior of the cakes leaden bullets are often discovered. The cakes should always be cut through the centre in order to detect this fraud.

The relative proportion of these numerous ingredients varies very much, not only in the samples from different countries, but in those of the same country. Thus Smyrna opium, though the average quantity of morphia which it yields may be stated to be 10 per cent., in five specimens examined by Mulder gave 10 per cent. in the best, and little more than 2 in the worst.

Professor Guibourt states Constantinople opium to yield only one half the quantity of morphia procurable from Smyrna opium; while Mr. Duncan of Edinburgh has obtained even 14 per cent. Guibourt also affirms that Egyptian opium yields only 3-7ths of the morphia obtainable from Smyrna opium; while Dr. Christison procured 10¾ per cent. from it. Of the Indian kinds Dr. Smyttan procured only 3 or 4 per cent. of morphia; while Dr. Christison obtained 8½ from the Malwa opium: and from Bengal opium Dr. Smyttan obtained 2 or 3½ per cent.; while Mr. Macfarlane of Edinburgh procured 7 per cent.

From English opium 5 per cent. may be obtained. From German opium Biltz procured 16½ to 20 per cent.; from some French opium Petit obtained 16 to 18 per cent., and Caventou the large amount of 22 to 28 per cent.

The extreme discrepancy of these results may be explained not merely by the varying seasons when the specimens were produced, and the different degrees of skill and dexterity in the chemists, but by the fact that the morphia is more easily and effectually separated when the opium is fresh; hence the large proportion found in European opium, which was not only cultivated with great care, but was analysed soon after it had been collected. It is not at all improbable that the morphia undergoes a change by age, and entirely evaporates from old specimens, in the same way as conia disappears from hemlock. [Conium.]

It is always proper to institute an examination into each new purchase of opium, to ascertain the presence and amount of morphia. Some specimens of opium, which to the eye present all the physical characters of the best Smyrna opium, even some of those deemed hitherto inimitable, such as the transparent agglutinated tears seen on cutting it across, are found on analysis devoid of the smallest trace of morphia. (*Journal de Pharmacie*, tom. xxiv., pp. 325, 446.)

The following test is proposed in the 'New Edinburgh Pharmacopœia,' and though not absolutely certain, is sufficiently so for common use. 'A solution from 100 grains, macerated 24 hours in two fluid ounces of water, filtered and strongly squeezed in a cloth, if precipitated by a cold solution of half an ounce of carbonate of soda in two waters, and heated till the precipitate shrinks and fuses, will yield a solid mass on cooling, which weighs, when dry, at least eleven grains; and if pulverised, dissolves entirely in solution of oxalic acid.'

More morphia would appear to be present in the specimens of European opium, which are obtained from the variety of poppy with violet-coloured petals, than in the Turkey opium; while that from the European white variety contains more narcotine than the Turkey. In Smyrna opium the morphia seems to be united with meconic acid, and to be not only more abundant, but more easily separated, and more completely purified from the narcotine and colouring matter, than that of Egypt, in which the morphia is united to sulphuric acid.

The great pains now taken in the culture and preparation of Indian opium will soon lead to a preference of it over the other kinds; and even now the specimens sent by Captain Jeremie surpass in purity and strength any which have ever been seen in this country, except some grown and prepared by Mr. Young of Edinburgh. If Indian opium contain generally more narcotine, it is on that account perhaps better suited to all cases in which the stimulating action is wished.

Good opium is not perfectly soluble in water; ¼th generally remains undissolved, consisting of the caoutchouc and resin. Constantinople opium however leaves no residuum of caoutchouc. When opium is entirely soluble in water, it may be suspected to have been prepared by boiling the bruised capsules and leaves, and it is of a very inferior kind. The specific gravity of good opium is 1·336, if great mechanical impurities are not present. It is very inflammable, and burns with a clear flame, and forms a transparent alcoholic solution: opium from the bruised capsules is not inflammable, and forms a turbid alcoholic solution. When gum arabic or tragacanth is used to adulterate it, the specimen forms, when rubbed with one part of alcohol and two of water, a tremulous gelatinous mixture.

The following table, by Mr. Pereira, will show at one view the principal characters of the crystalline constituents of opium:—

Tabular View of the Principal Characters of the Crystalline Principles of Opium.

Characters.	Morphia.	Codeia.	Narcotina.	Meconine.	Narceine.	Paramorphia, or Thebaine.	Pseudomorphia.
Taste . . .	Bitter	Bitter	Insipid	Rather acrid	Slightly bitter and metallic	Rather acrid and metallic	..
Fuses at . .	Above 240°	302°, or in boiling water	338°	194°, or in boiling water	198°, or in boiling water	302°	Hardly fusible

It must be obvious that a substance of so complicated a nature cannot act uniformly on organised beings, even supposing them to be always constituted alike, which never is the case, since they vary according to age, constitution, habits of life, states of disease, and idiosyncrasy, &c. Some of the effects which follow the employment of opium have been attributed to one principle and some to another, but, with a few exceptions, nothing positive has been ascertained: morphia is by no means the only sedative principle, and narcotine, so long regarded as the stimulating principle, is, when pure, nearly if not quite inert. The odorous principle is unquestionably powerful, though it has no resemblance to hydrocyanic acid. The collectors of opium are generally pale and affected with tremblings. If opium be heated, the odour evolved is fatal to animals, and persons have fallen down in a state of insensibility from breathing an air charged with the vapour of opium in some pharmaceutical processes.

It is most probable that the extractive and resinous principles, with the meconic acid, which seems to modify the properties of the morphia, are the stimulating ingredients of opium, and that the getting rid of some or all of these, as in the watery extract of opium, and a few of the secret preparations of opium, constitute the superiority of these preparations, as calmants, over crude opium, or the officinal preparations in which they are retained.

A most extensive series of experiments have been instituted to determine the effects of opium: on vegetables by Marcet and Macaire, on animals by Charvet, and on man by numerous physiologists, including Charvet. From these it appears that opium acts as a poison to plants, by destroying their irritability. According to Charvet, in the case of the sensitive plant, where the opium failed to kill the subject of experiment, and it slowly recovered its irritability, yet the further growth was completely stopped. 'In the animal kingdom Charvet tried its effects on mammals, birds, reptiles, amphibia, fishes, insects (both in their perfect and larval states), the annelides, the mollusca, polypiphera, and polygastrica, and found that it acted on all as a poison, but with somewhat different effects according to their organization. Thus on man it may produce congestion of the brain (marked by sopor and apoplectic symptoms), or irritation of the brain and spinal marrow (indicated by convulsions and pain), or a sedative effect (manifested by paralysis).

In other mammals, two kinds of effects are seen for the most part; the one of irritation, the other of diminished nervous power, symptoms of congestion being altogether wanting or very slight. This difference of effect corresponds with a difference in the development of the brain.

In the invertebrated animals, no symptoms of irritation seem to be caused by opium. This poison in them acts only on the contractile tissues, and produces symptoms of weakness or loss of contractile power.

In the animal series, the action of opium varies with the degree of development of the nervous system; and in the lowest orders the effects are quite analogous to those observed in vegetables. (Pereira.)

Much disputation has taken place respecting the question, whether opium be a stimulant or a sedative; and most unnecessarily, as its action depends, in general, on the quantity taken, the frequency of repetition, and the state of the system when it is administered. That to persons in health, if the dose be small, it is a stimulant, seems unquestionable; and this is proved by the fact that the habitual opium-eaters consume it for the sake of its primarily stimulant effect, and not for the sake of the depression, languor, and suffering which succeed. The different degrees of action, resulting from a difference of dose, are so ably given by Mr Pereira, that they may be quoted here verbatim.

1. *First Degree of Operation.*—'In small doses, such as

from a quarter of a grain to one grain, opium generally acts as a stimulant, though in this respect the symptoms are not uniform. Usually the vascular system is somewhat excited, and a sensation of fulness is experienced about the heart. The excitement in the cerebral vascular system is accompanied by alterations in the condition of the nervous functions. The mind is exhilarated, the ideas flow more quickly, a pleasurable or comfortable condition of the whole system is experienced, which is difficult to describe; there is a capability of greater exertion than usual. These symptoms are followed by a diminution of muscular power, and of susceptibility to the impression of external objects; a desire of repose is experienced, with a tendency to sleep. While these effects are taking place, the mouth and throat become dry, and hunger is diminished, though the thirst is increased; and slight constipation usually follows.

'Such are the common effects of a small dose of opium on persons unaccustomed to its use; but by repetition the influence of this agent becomes remarkably diminished, and those therefore who resort to it for the purpose of producing a pleasurable stimulus are obliged to increase the quantity in order to keep up an equal effect.

2. *Second Degree of Operation.*—'Given in a full medicinal dose, such as two or four grains, the stage of excitement is soon followed by that of depression. The pulse, which at first is increased in fulness and frequency, is afterwards reduced below the natural standard. The skin becomes hot, the mouth and throat dry, the appetite diminished, the thirst increased, and frequently nausea or even vomiting is induced. The symptoms of excitement soon pass away, and a state of torpor succeeds; the individual feels indisposed to exertion, the muscular system appears enfeebled, the force of impressions on the organs of the senses is diminished, and the ideas become confused. This state is followed by an almost irresistible desire to sleep, which is frequently attended by dreams, sometimes of a pleasing, at others of a frightful nature.

'These effects are usually succeeded by constipation (which may continue for several days), by nausea, furred tongue, headache, and listlessness.

3. *Third Degree of Operation: Poisonous Effects of Opium*, as given by Dr. Christison.—'The symptoms of poisoning with opium, when it is administered at once in a dangerous dose, begin with giddiness and stupor, generally without any previous stimulus. The stupor rapidly increasing, the person becomes motionless and insensible to external impressions; he breathes very slowly, generally lies quite still, with the eyes shut and the pupils contracted; and the whole expression of the countenance is that of deep and perfect repose. As the poisoning advances, the features become ghastly, the pulse feeble and imperceptible, the muscles exceedingly relaxed, and, unless assistance is speedily procured, death ensues. If the person recovers, the stupor is succeeded by prolonged sleep, which commonly ends in twenty-four or thirty-six hours, and is followed by nausea, vomiting, giddiness, and loathing of food.'

The quantity which can produce a fatal effect in a person unaccustomed to its use is very small, even four grains; and in children, owing to the large quantity of blood which naturally goes to the brain, and the great impressibility of their nervous system, a very minute portion of opium, or of its numerous preparations, open or disguised, can produce death. These facts constitute a strong reason for unofficial persons refraining from its employment, and also for avoiding in this place all details connected with its medical use. It is undoubtedly one of the most important means of alleviating human suffering, when appropriately administered, and yet one of the greatest banes when abused. It is by the self-dosing in general that the practice of opium-eating is acquired; and it is the more necessary to warn such persons against commencing the use of it, even for the legitimate purpose of overcoming disease, as they may inadvertently lapse into habits which they may never be able to shake off. Further, it should be known by those who are disposed to adopt this practice, that the habitual consumers of this drug have recourse to it again and again, not so much for the sake of the pleasurable sensations it can excite, as to *escape the misery*, mental and bodily, which their previous indulgence has entailed upon them. Of these facts, the account of opium-eating among the Turks, as detailed by Dr. Oppenheim, are confirmatory:—

Turkish opium-eaters: Theriaki.—'The causes leading to the use of opium are many, and among them may be reckoned the following: long-continued diarrhœa, as a remedy for which opium is used in the first instance, and its use afterwards continued from habit; chronic coughs, in which opium is used as a popular medicine; habitual drunkards also frequently have recourse to opium, as a new stimulus, after they have abjured wine in some fit of repentance. Persons holding high offices or dignities in the state also have recourse to opium, when the preservation of their character forbids them the use of wine; some very strict believers also take opium as a restorative in cases of great exertion, as the Tartars (couriers), who travel with astonishing celerity.

'Opium-eaters generally begin with doses of from half a grain to two grains, and gradually increase the quantity till it amounts to two drachms and sometimes more a day; they usually take the opium in pills, but avoid drinking any water after having swallowed them, as this is said to produce violent cholic; to make it more palatable, it is sometimes mixed with syrups or thickened juices; but in this form it is less intoxicating, and resembles mead; it is then taken with a spoon, or dried in small cakes, with the words "Mash Allah" (the work of God) imprinted on them.

'The effect of the opium manifests itself one or two hours after it has been taken, and lasts for four or six hours, according to the dose taken and the idiosyncrasy of the subject. In persons accustomed to take it, it produces a high degree of animation, which the Theriaki represent as the acme of happiness.

'The habitual opium-eater is instantly recognised by his appearance. A total attenuation of body, a withered yellow countenance, a lame gait, a bending of the spine, frequently to such a degree as to assume a circular form, and glossy deep-sunken eyes, betray him at the first glance. The digestive organs are in the highest degree disturbed; the sufferer eats scarcely anything, and has hardly one evacuation in a week; his mental and bodily powers are destroyed,—he is impotent. By degrees, as the habit becomes more confirmed, his strength continues decreasing, the craving for the stimulus becomes even greater, and to produce the desired effect, the dose must constantly be augmented.

'When the dose of two or three drachms a day no longer produces the beatific intoxication so eagerly sought by the Opiophagi, they mix the opium with corrosive sublimate, increasing the quantity till it reaches ten grains a day; it then acts as a stimulant.*

'After long indulgence the opium-eater becomes subject to nervous or neuralgic pains, to which opium itself brings no relief. These people seldom attain the age of forty, if they have begun to use opium at an early age. The fasts in the month of Ramadan are for them fraught with the most dreadful tortures, as during the whole of that month they are not allowed to take anything during the day. It is said that to assuage their sufferings, they swallow, before the morning prayer, besides the usual dose, a certain number of other doses, each wrapped up in its particular paper, having previously calculated the time when each envelope shall be unfolded, and allow the pill to produce the effects of their usual allowance. When this baneful habit has become confirmed, it is almost impossible to break it off; the torments of the opium-eater, when deprived of this stimulant, are as dreadful as his bliss is complete when he has taken it; to him night brings the torments of hell, day the bliss of paradise. Those who do make the attempt to discontinue the use of opium, usually mix it with wax, and daily diminish the quantity of the opium, till the pill at last contains nothing but wax.'—(Dr. Oppenheim's *State of Medicine in Turkey*; *British and Foreign Medical Review*, October, 1837, p. 594.)

Coleridge.—'For ten years the anguish of my spirit has been indescribable, the sense of my danger staring, but the consciousness of my guilt worse, far worse than all!

'I have prayed, with drops of agony on my brow; trembling, not only before the justice of my Maker, but even before the mercy of my Redeemer.

'"I gave thee so many talents—what hast thou done with

---

* Hence the name sometimes applied to such persons, '[illegible] yiyen,' 'swallowers of sublimate.' (Notes to 'Childe Harold,' Canto ii, Stanza [illegible].)

[illegible] the year 95 A.D. In the time of Confucius [illegible] bodkin, on the inner bark of the [illegible]. The Chinese paper has been supposed to be made [illegible] mistake; silk by itself cannot be reduced [illegible] suitable for making paper. Refuse silk is [illegible] occasionally used with other things, but the greatest part of the Chinese paper is made from the inner bark of the mulberry and some other trees, but chiefly from the bamboo. The Chinese also make paper from cotton and other rags, and a coarse yellow sort for wrappers is made from rice-straw. Only the second skin of the bark of the bamboo is used, which is beaten into a pulp with water. The Chinese can make sheets of a large size, the mould on which the pulp is made into paper being sometimes ten or twelve feet long, and very wide, and managed by means of pulleys. It is formed of fine threads of bamboo, as ours are of wire. To prevent the ink from running, the sheets are dipped into a solution of alum, which, as their ink is thicker than ours, is generally sufficient for the purpose, but sometimes isinglass is mixed with the solution of alum. (Du Halde's *China*, vol. ii. p. 415; Davis's *Chinese*, chap. xvii.)

Before the invention of paper the papyrus was in general use among European nations, but when the Saracens conquered Egypt in the seventh century, it could no longer be procured, and parchment became so dear that the writing on ancient manuscripts was erased to allow of their being re-written upon. [Palimpsest Manuscripts.]

The Arabians, in the seventh century, appear to have either discovered, or to have learned from the Chinese, the art of making paper from cotton; for it is known that a manufacture of such paper was established at Samarcand about the year [illegible] A.D. The Arabians seem to have carried the art to Spain, and to have there made paper from linen and hemp as well as from cotton. (*Journal of Education*, No. [illegible])

A person of the name of Tate is said to have had a paper-mill in Hertfordshire early in the sixteenth century; and another is said to have been established in 1588 at Dartford in Kent by a German, who was knighted by queen Elizabeth. Previously to this, and for some time afterwards, our principal supplies were from France and Holland. The making of paper in England had made little progress even so late as [illegible]. Fuller has the following remarks respecting the paper of his time:—'Paper participates in some sort of the character of the country which makes it; the Venetian being neat, subtle, and court-like; the French, light, slight, and slender; and the Dutch, thick, corpulent, and gross, sucking up the ink with the sponginess thereof.' He complains that the making of paper was not sufficiently encouraged, 'considering the vast sums of money expended in our land for paper out of Italy, France, and Germany, which might be lessened were it made in our nation.'

Thomas [illegible], a stationer, by the introduction of foreign improvements in [illegible], gave a great impulse to the manufacture of paper. Still, notwithstanding the great increase of demand and application of machinery, it was much retarded by the heavy duty of 3d. per pound on all writing and printing papers, accompanied with vexatious Excise regulations; and it was not till the reduction of the duty [illegible] that the manufacture could be said to be allowed fair play.

In the making of paper any fibrous vegetable substance [illegible] the inner bark of trees, the stalks of the [illegible] the leaves of the vine, the bine of the hop and [illegible] de-[illegible]. Some of the substances [illegible] for the making of ex-[illegible] been found to answer so [illegible] rags. The sweepings of the [illegible] is not fit [illegible] beaten into a suitable [illegible] substance [illegible] whether from the bark of [illegible] the general pro-[illegible] bruised in [illegible] filaments and [illegible] and [illegible] similar [illegible] fibrous [illegible] render [illegible] inter-[illegible] separate, with-

The rags of our own country do not constitute a fourth part of the quantity which we use in making paper. Italy and Germany furnish the principal supplies. They are imported in bags of about 4 cwts., each bag being marked in such a manner as to indicate the quality of the rags which it contains.

In every paper-mill the first business is to sort the rags and cut them into small pieces. This is done by women, each of whom is provided with a large knife to cut the rags. Threads and seams are carefully put by themselves: if ground with the cloth, they would form specks in the paper. The rags, when cut, are thrown in to five or six different compartments of a large chest, according to their quality. Only the finest linen rags are used for the best writing-paper, but cotton as well as linen rags are now used for printing-paper. A good workwoman can sort and cut about a hundredweight a day. Hempen rags are used for coarse papers, and old cordage and tarred ropes for brown wrapping-papers.

The rags are now to be washed, which is done either with hot water in a fulling-mill, such as is used for scouring cloth, or they are subjected for some hours to the action of steam. Formerly they were half rotted to prepare them for being more easily torn and beaten into a pulp. But in this process the fibre was partially destroyed, and the texture of the paper materially injured.

Previous to the important discovery that chlorine possesses the property of destroying all vegetable colours, paper-makers could only bleach their rags by subjecting them to various washings in alkaline leys, and by exposing them to the dew and light; and after all their pains they obtained a paper so imperfectly white that they were obliged to mask the defect by tinging it with a shade of blue. But now, by the proper application of chlorine, either in the form of the simple gas or in combination with [illegible] (chloride of lime), the colour can be perfectly discharged, and the paper rendered, if necessary, of the [illegible] white. Objections have been justly made to the improper application of chlorine in bleaching paper. Sometimes [illegible] applied in such quantity, or for such a time, as to injure the substance of the fibre, and sometimes the paper, after [illegible] made, is bleached with chlorine in such a manner that the ink turns brown, and there have been instances in which the colour has been nearly discharged altogether, leaving the sheet almost as it was before it was written or printed [illegible]. But we believe it is now generally admitted that [illegible], judiciously applied, is not in the smallest degree injurious to the paper, or liable, in any length of time, to alter the colour of the ink.

The rags, after being washed, are subjected to the action of a revolving cylinder, the surface of which is furnished with a number of sharp teeth or cutters, which are so placed as to act against other cutters fixed beneath the cylinder. The rags are kept immersed in water, and subjected to the action of the cutters for several hours till they are minutely divided and reduced to a thin pulp. During [illegible] process a quantity of the chloride of lime or of chlorine [illegible] is mixed with the rags, by which the pulp is rendered perfectly white.

The pulp, or *stuff*, as it is technically called, is now ready to be made into paper, which is done either by hand or [illegible] machine. We shall first describe, as briefly as we can, [illegible] process of making paper by hand. We shall not enter [illegible] any niceties of detail, which, in such things, are of no use [illegible] those who understand the art, and of very little to [illegible] who do not. A clear view of the details can only [illegible] obtained by actual inspection.

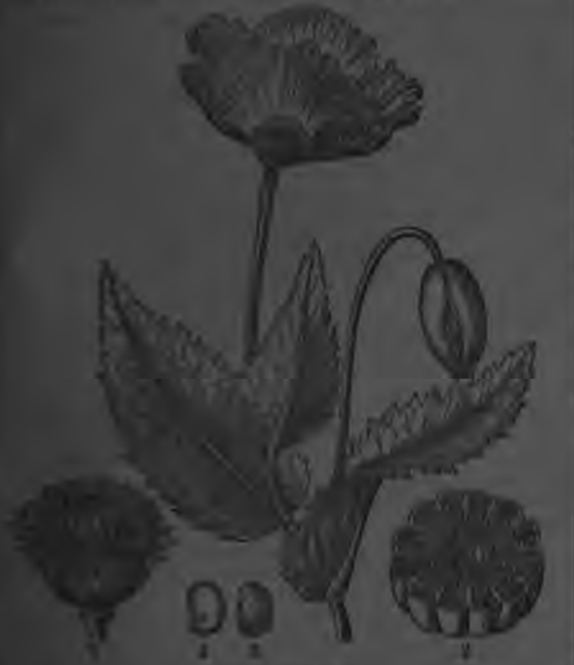
The stuff is put into a large vat, and is kept at a proper temperature either by a stove or steam-pipe, and the [illegible] matter is held in even suspension by a continual [illegible] carried on in the vat by means of what is technically called a *hog*, or by other improved apparatus.

The paper is made with a *mould* and *deckle*. The mould is a shallow square *frame* covered with wire-cloth, a little larger than the sheet intended to be made up[illegible]. The wire-cloth is now generally woven in a loom like cloth, and makes no wire-marks on the paper; but the [illegible] fashioned wire-cloth consists of a number of parallel wires stretched across the frame, very close together, and crossed at right angles by other stronger wires about an [illegible] apart. These thicker wires make the wire-marks of the paper, the stuff being there thinner than on the rest of the sheet. The deckle is a very thin frame of wood which [illegible]

Pereira, in *Medical Gazette*; and Holland, *Medical Notes and Reflections*.)

PAPAVERACEÆ, so called after the subject of the preceding article, form a small natural order of Exogens, readily known by their deciduous calyx, usually tetramerous flowers, indefinite hypogynous stamens, and parietal placentæ; added to which, they have leaves without stipules, and their stems discharge a turbid white, yellow, or orange-coloured juice when wounded. Their seeds moreover contain a bland oil, lodged in a copious albumen, within which is situated a minute embryo. They consist for the most part of herbs, which are usually of only annual duration; but a few are shrubby, the most remarkable case of that kind being a genus called Dendromecon, a native of California, which is a true shrub, with the aspect of a Cistus. The greater part of the species inhabit the temperate parts of the Old World; but a few also occur in Australia, at the Cape, and in North America. Their active qualities are usually dangerous, but are for the most part of little moment, except in the case of the Papaver somniferum, or Opium Poppy [PAPAVER], the properties of which have been already noticed. It is however probable that in most cases the milky juice is narcotic and the oil of the seeds harmless: an apparent exception to the latter statement occurs in Argemone mexicana, whose seeds are said to be narcotic, especially when smoked; but it is probable that in this case it is in the coats of the seed that the poisonous principle resides, rather than in the oil itself.

Some Papaveraceæ have no petals, as Bocconia, thus corresponding with Thalictrum and other apetalous Ranunculaceæ, with which order they are closely connected through Platystemon, a Californian annual with disjoined carpels. (Lindley's *Natural System*, p. 7; Endlicher, *Genera Plantarum*, p. 852; and Dierbach's *Arzneikräfte*, p. 31.)

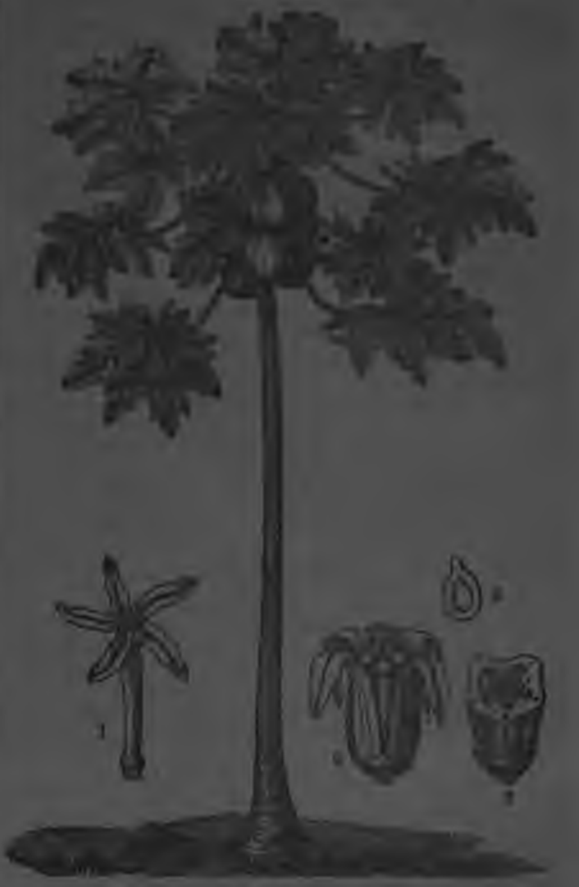


Papaver somniferum.

1, the stamens and pistil; 2, a transverse section of the capsule; 3, a seed; 4, the same cut in half, so as to show the embryo.

PAPAW. [CARICA.]

PAPAYACEÆ, so called from Carica Papaya, the principal species, of which a full account has already been given [CARICA], are a very small natural order of Exogenous plants, consisting of the genus Carica alone, and apparently allied to Cucurbitaceæ and Passifloraceæ, with the former of which it corresponds in its gourd-like fruit, with parietal placentæ, and in its diclinous sexes; while it approaches the latter also in placentation, in its superior succulent fruit, and in the structure of its seeds. The order is remarkable as an exception for having monopetalous male flowers and polypetalous females, and in its vegetation for its simple unbranched stems, growing only by the gradual development of a terminal bud. For a full account of the Papaw tree the reader is referred to CARICA.



Carica Papaya.

1, a monopetalous male flower; 2, a polypetalous female flower; 3, a transverse section of the ovary; 4, a longitudinal section of a seed.

PAPENBURG is a flourishing town in the lordship of Meppen and the province of Osnabrück, in 53° 33′ N. lat. and in 7° 25′ E. long. Towards the end of the seventeenth century a few Germans formed a small settlement on the neighbouring moors for the purpose of digging and selling peat, which by degrees has become a place of great trade. A canal seven miles in length, connected with several others, runs through the Drosler Syhl (which is the harbour of the Papenburg ships) into the Ems. The town contains two Roman Catholic churches, three schools, and between 400 and 500 houses. The inhabitants, 3600 in number, gain their livelihood chiefly by ship-building and navigation: they build annually about 60 ships for East Friesland, as well as for their own use, and have one hundred ships of their own, from eighty to ninety tons burden, manned with 6 or 7 men, each of which, when first launched and equipped for sea, is worth 10,000 or 12,000 Dutch florins. During the French revolution several hundred ships sailed under the neutral flag of Papenburg. Besides saw-mills, sail-cloth, and rope manufactories, there are some brandy distilleries and lime-kilns: the quantity of peat annually dug on the moors is very great, and it forms an important article of export to the ports of the Baltic and the German Ocean.

PAPER. In early times the materials used for writing upon were chiefly such as only required some little mechanical fashioning to fit them for that purpose. Characters were engraved on flat stones made smooth, or were impressed in clay, which was afterwards dried and hardened by sun or fire, as in the Babylonian bricks. Thin boards of wood covered with wax or some similar composition, and plates of ivory and of metal, have been used; but a more convenient material was afforded by the leaves of some species of trees. The skins and intestines of animals have also been made fit for writing upon; but wherever the Egyptian papyrus was introduced, all these things fell into disuse, except parchment, which is still preferred for certain purposes. [PARCHMENT; PAPYRUS.]

The art of making paper from fibrous matter reduced to a pulp in water appears to have been first discovered by the

Chinese about the year 95 A.D. In the time of Confucius they wrote with a style, or bodkin, on the inner bark of the bamboo. The Chinese paper has been supposed to be made of silk, but this is a mistake; silk by itself cannot be reduced to a pulp suitable for making paper. Refuse silk is indeed occasionally used with other things, but the greatest part of the Chinese paper is made from the inner bark of the bamboo and some other trees, but chiefly from the bamboo. The Chinese also make paper from cotton and linen rags, and a coarse yellow sort for wrappers is made from rice-straw. Only the second skin of the bark of the bamboo is used, which is beaten into a pulp with water. The Chinese can make sheets of a large size, the mould on which the pulp is made into paper being sometimes ten or twelve feet long, and very wide, and managed by means of pulleys. It is formed of fine threads of bamboo, as ours are of wire. To prevent the ink from running, the sheets are dipped into a solution of alum, which, as their ink is thicker than ours, is generally sufficient for the purpose, but sometimes fish-glue is mixed with the solution of alum. (Du Halde's *China*, vol. ii., p. 415; Davis's *Chinese*, chap. xvii.)

Before the invention of paper the papyrus was in general use among European nations, but when the Saracens conquered Egypt in the seventh century, it could no longer be procured, and parchment became so dear that the writing of antient manuscripts was erased to allow of their being re-written upon. [PALIMPSEST MANUSCRIPTS.]

The Arabians, in the seventh century, appear to have either discovered, or to have learned from the Chinese, the art of making paper from cotton; for it is known that a manufactory of such paper was established at Samarcand about the year 706 A.D. The Arabians seem to have carried the art to Spain, and to have there made paper from linen and hemp as well as from cotton. (*Journal of Education*, No. 10.)

A person of the name of Tate is said to have had a paper-mill at Hertford early in the sixteenth century; and another is stated to have been established in 1588 at Dartford in Kent, by a German, who was knighted by queen Elizabeth. Previously to this, and for some time afterwards, our principal supplies were from France and Holland. The making of paper in England had made little progress even so late as 1662. Fuller has the following remarks respecting the paper of his time:—'Paper participates in some sort of the character of the country which makes it; the Venetian being neat, subtle, and court-like; the French, light, slight, and slender; and the Dutch, thick, corpulent, and gross, sucking up the ink with the sponginess thereof.' He complains that the making of paper was not sufficiently encouraged, 'considering the vast sums of money expended in our land for paper out of Italy, France, and Germany, which might be lessened were it made in our nation.'

Thomas Watson, a stationer, by the introduction of foreign improvements in 1713, gave a great impulse to the manufacture of paper. Still, notwithstanding the great increase of demand and application of capital, it was much retarded by the heavy duty of 3*d.* per pound on all writing and printing papers, accompanied with vexatious Excise regulations; and it was not till the reduction of the duty to 1½*d.* per pound on all kinds that the manufacture could be said to be allowed fair play.

In the making of paper any fibrous vegetable substance may be used, as the inner bark of trees, the stalks of the nettle, the tendrils of the vine, the bine of the hop, and even wheat-straw, upon paper made from which a book describing the process was published. Some of the substances mentioned answer well enough, but the making is too expensive. Nothing however has yet been found to answer so well as linen, hempen, or cotton rags. The sweepings of the cotton-mills are also much used. Woollen cloth is not fit for the purpose, because it cannot be beaten into a suitable pulp, and gives a hairy texture to the surface.

In all kinds of paper-making, whether from the bark of trees or other fibrous matter, or from rags, the general process is the same. The fibrous material is cut and bruised in water till it is separated into fine and short filaments, and becomes a sort of pulp. This pulp is taken up in a thin and even layer upon a mould of wire cloth, or something similar, which allows the water to drain off, but retains the fibrous matter, the filaments of which are, by the process of reduction to pulp and subsequent drying and pressing, so interwoven or felted together that they cannot be separated without tearing, and thus form paper.

The rags of our own country do not constitute a fourth part of the quantity which we use in making paper. Italy and Germany furnish the principal supplies. They are imported in bags of about 4 cwts., each bag being marked in such a manner as to indicate the quality of the rags which it contains.

In every paper-mill the first business is to sort the rags and cut them into small pieces. This is done by women, each of whom is provided with a large knife to cut the rags. Threads and seams are carefully put by themselves: if ground with the cloth, they would form specks in the paper. The rags, when cut, are thrown in to five or six different compartments of a large chest, according to their qualities. Only the finest linen rags are used for the best writing-paper, but cotton as well as linen rags are now used for printing-paper. A good workwoman can sort and cut about a hundredweight a day. Hempen rags are used for coarse papers, and old cordage and tarred ropes for brown wrapping-papers.

The rags are now to be washed, which is done either with hot water in a fulling-mill, such as is used for scouring cloth, or they are subjected for some hours to the action of steam. Formerly they were half rotted to prepare them for being more easily torn and beaten into a pulp. But by this process the fibre was partially destroyed, and the texture of the paper materially injured.

Previous to the important discovery that chlorine possesses the property of destroying all vegetable colours, paper-makers could only bleach their rags by subjecting them to various washings in alkaline leys, and by exposing them to the dew and light; and after all their pains they only obtained a paper so imperfectly white that they were obliged to mask the defect by tinging it with a shade of blue. But now, by the proper application of chlorine, either in the form of the simple gas or in combination with lime (chloride of lime), the colour can be perfectly discharged, and the paper rendered, if necessary, of the purest white. Objections have been justly made to the improper application of chlorine in bleaching paper. Sometimes it is applied in such quantity, or for such a time, as to injure the substance of the fibre, and sometimes the paper, after it is made, is bleached with chlorine in such a manner that the ink turns brown, and there have been instances in which the colour has been nearly discharged altogether, leaving the sheet almost as it was before it was written or printed upon. But we believe it is now generally admitted that chlorine, judiciously applied, is not in the smallest degree injurious to the paper, or liable, in any length of time, to alter the colour of the ink.

The rags, after being washed, are subjected to the action of a revolving cylinder, the surface of which is furnished with a number of sharp teeth or cutters, which are so placed as to act against other cutters fixed beneath the cylinder. The rags are kept immersed in water, and subjected to the action of the cutters for several hours till they are minutely divided and reduced to a thin pulp. During this process a quantity of the chloride of lime or of chlorine gas is mixed with the rags, by which the pulp is rendered perfectly white.

The pulp, or *stuff*, as it is technically called, is now ready to be made into paper, which is done either by hand or by machine. We shall first describe, as briefly as we can, the process of making paper by hand. We shall not enter into any niceties of detail, which, in such things, are of no use to those who understand the art, and of very little to those who do not. A clear view of the details can only be obtained by actual inspection.

The stuff is put into a large vat, and is kept at a proper temperature either by a stove or steam-pipe, and the fibrous matter is held in even suspension by a continual motion carried on in the vat by means of what is technically called a *hog*, or by other improved apparatus.

The paper is made with a *mould* and *deckle*. The mould is a shallow square frame covered with wire-cloth, and a little larger than the sheet intended to be made upon it. The wire-cloth is now generally woven in a loom like cloth, and makes no wire-marks on the paper; but the old-fashioned wire-cloth consists of a number of parallel wires stretched across the frame, very close together, and crossed at right angles by other stronger wires about an inch apart. These thicker wires make the wire-marks of the paper, the stuff being there thinner than on the rest of the sheet. The deckle is a very thin frame of wood which fits slides upon the mould, and is required to retain the stuff on the mould and to limit the size of the sheet.

The *dipper*, or *vatman*, inclining the mould a little towards him, dips it into the vat with the deckle upon it, and lifts it up again horizontally. He shakes it to distribute the stuff equally, and the water drains through the wire. He lays the mould on the edge of the vat and takes off the deckle, which he requires to apply to another mould. After remaining two or three seconds to drain, the mould is taken by another workman, the *coucher*, who, having deposited the sheet of paper upon a felt, or piece of woollen cloth, returns the mould to the dipper, who in the meantime has made another sheet, which stands on the vat ready to be couched upon another felt spread over the former sheet. Thus they proceed till they have made a pile of sheets, called a *post*, consisting of six or eight quires. This post, with its felts, is placed in the *vat-press*, and subjected to a strong pressure to force out the superfluous water, and to give firmness and solidity to the paper. The pile is then removed from the vat-press, the felts taken out, and the sheets are pressed again by themselves. They are then taken from the press, and hung up, five or six together, in the *drying-room*.

The paper is now made, and only requires finishing, but the greater number of the finishing processes are only required for writing-paper, common printing-paper and wrapping-papers being ready for packing up when dried.

Writing-paper is dipped, five or six sheets together, into a tub of size, and afterwards pressed to force out the superfluous size. It is then hung up again in the drying-room. Printing-paper is sized in the stuff. Every sheet is now examined, imperfections removed, and bad sheets taken out. A large pile of paper is then made, and pressed with great force to render the sheets quite flat and smooth. The pile is then taken down sheet by sheet, and another made, by which new surfaces are brought into contact with each other, and the pile again pressed strongly. This operation, which is called *parting*, is done two three times for the best papers. The paper is now counted into quires, folded, and packed up into reams.

The size is made from skins and other animal substances, and is required to prevent the ink from spreading among the fibres by capillary attraction. Blotting-paper is not sized.

The paper-making machine is constructed in such a manner as to imitate, and in some respects to improve, the processes used in making paper by hand; but its chief advantages are, that paper can be made of any size which can practically be required, and with a degree of rapidity which leaves the other mode of making it at an immeasurable distance. As much as 25 square feet can be made in a minute, and consequently 15,000 square feet in a working day of ten hours.

The paper-making machine was invented by Mr. Fourdrinier, and as now used, with the improvements applied to it by himself and others, is, in the simplicity and ingenuity of its contrivances, not surpassed by any other in the whole range of British machinery.

We will describe the process of making paper by the machine as briefly as we can, referring those who wish for more minute information to an article in No. 96 of the 'Penny Magazine,' which is accompanied by a large wood engraving of the machine itself.

The pulp is first made to flow from the vat upon a wire strainer, or sifter, which moves rapidly up and down so as to force the fine filaments of the pulp through the wire, whilst it retains any knots or other unsuitable matter. Having passed through the sifter, the pulp flows over a ledge in a regular and even stream, and is received upon an endless web of wire-gauze, which presents an uninterrupted surface of five or six feet long. The wire-web moves forward with a motion so regulated, as, taken in connection with the quantity of pulp allowed to flow upon it, to determine the thickness of the paper. At the same time a shaking motion is given, from side to side, to the wire web, which assists to spread the pulp evenly, and also to facilitate the separation of the water, which passes through the wire; by which means the pulp solidifies as it advances, and is at the same time prevented from flowing over the sides by straps which regulate the width of the paper. Before the pulp, now so [illegible], quits the plane of wire, it is pressed by a roller covered with felt, and is then taken up by an endless web of felt, which forms an inclined plane, and gradually moving forward absorbs a further portion of the moisture. The pulp is now raised by a pair of rollers, between which it is pressed, and then it passes upon another inclined plane of felt, which conducts it to another pair of pressing rollers. The pulp is now become paper, and only requires to be made dry and smooth. To effect these objects the machinery conducts it over the polished surface of a large cylinder heated by steam. From this cylinder it passes to a second, larger and hotter, and then to a third, which is still hotter than the second. After this it is subjected to the pressure of a woollen cloth, which confines it on one side while the cylinder smooths it on the other. It is then conducted by another roller to a reel, on which it is wound, perfectly dry and smooth, and ready to be cut into sheets for use. In two or three minutes the pulp, which is introduced upon the wire web at one extremity of the machine, is delivered at the other in the state of perfect paper.

In printing-paper the size is commonly added to the pulp, but writing-paper is sized after the sheets are cut, as in hand-made paper.

The paper, after it is cut, is examined, to remove knots or specks, and to put aside damaged sheets. It is then counted into quires of 24 sheets and folded, and lastly put up into reams of 20 quires, pressed in the reams, and tied up in wrappers for sale.

Machines for cutting the paper into sheets of any size which may be required, have been invented by different persons. They are separate from the paper-making machine, and are beautiful contrivances, but too complicated for description without the assistance of engravings.

In most of the Fourdrinier machines a partial vacuum is produced under the endless wire-web by means of large air-pumps. The atmosphere is thus made to press upon the pulp, and the moisture is forced through the wire. Owing however to the change of stroke of the pistons, a uniform degree of vacuum cannot be maintained, so that the pulp receives various degrees of pressure, and consequently the paper is made of unequal thickness. To remedy this defect, by rendering the vacuum as uniform as possible, two patents were taken out in 1839, one of which proposes to effect the purpose by substituting a revolving fan for the air-pump, and the other by using hydraulic air-pumps working on the principle of gas-holders, instead of the common ones.

Various patents have been taken out for improvements in parts of the machinery, or for other machinery to be applied in various stages of the process. One was taken out by Mr. Dickinson for an apparatus to separate the knots and lumps from the pulp, by making it pass through the periphery of a revolving cylinder constructed of an endless spiral wire attached to metal bars. Other improved processes for the same purpose have been invented. A patent was taken out by Messrs. Towgood and Smith, the object of which is to apply the size to the paper as it comes in a continuous sheet upon the endless wire-web. The operation in this apparatus is performed by rollers, the surfaces of which are supplied with size, which is transferred from them to the newly-made paper as it passes between the rollers. Mr. Dickinson has also a patent for uniting two layers of pulp in order to produce paper of an extraordinary thickness. The combination of two or more sheets of pulp has been long employed in the making of thick drawing-paper and Bristol boards by the process called couching, but Mr. Dickinson's contrivance affords the means of doing it in a common paper-making machine.

Various wire-marks, or water-marks, as they are called, were formerly applied to paper to distinguish it. On the paper used by Caxton and the other early printers, these marks consisted of an ox-head and star, a collared dog's head, a crown, a shield, a jug, &c. A head with a fool's cap and bells gave name to the paper called foolscap, and post paper seems to have derived its name from the mark of a horn, which was formerly carried by the postman, and blown to announce his arrival. Hand-made paper is now commonly marked with the name of the maker, and the date of the year when it was made.

PAPER TRADE. The manufacture of paper being a branch of industry which does not necessarily call for the employment of any large capital, is carried on in every country, and consequently from no one is there any considerable exportation. England is perhaps better qualified than any other country for the cheap production of paper, because of the successful application to that purpose of extensive machinery; but this great advantage is to some extent counterbalanced by the impediments thrown in the way by Excise regulations, and the shipments are consequently in great part confined to our own colonies and foreign possessions. In the account of exports kept at the Custom-House, paper is not distinguished from other articles of stationery, but it necessarily forms the greatest part of the articles entered under that name. The total value of stationery exported in 1837 was 198,349*l.*, and of this sum the large proportion of 136,424*l.* was made up of shipments to our foreign possessions. It was shown by an account produced before the Commissioners of Excise Enquiry in 1835 that the weight of paper of all kinds exported in the previous year did not much exceed 4 per cent. of the quantity made.

Until 1837 the duty on paper was charged in two classes. That made wholly out of old tarred rope, without extracting the pitch or tar, was considered as second-class paper, and paid only a duty of 1½*d.* per lb., while paper made of all other materials was considered as first class paper, and was charged with a duty of 3*d.* per lb. In the year above mentioned this distinction was abolished, and the duty on all kinds of paper was fixed at 1½*d.* per lb., which gave an immediate impulse to the trade. The effect of this change in augmenting the quantity used may be seen from the following figures:—

The quantity of paper of each class made in the United Kingdom in 1835 and 1836 was as follows:—

	1835. lbs.	1836. lbs.
First class .	56,179,555	66,202,689
Second class .	17,863,095	15,906,258
Total .	74,042,650	82,108,947

The quantity made in the two following years, when the classification was abolished, was—

1837 .	88,950,845 lbs.
1838 .	93,466,286

The duty collected in each of these years was—

1835 . .	£813,688
1836 . .	751,113
1837 . .	555,942
1838 . .	584,164

The rates of duty chargeable on the importation of paper from any foreign country are:—

On brown paper made from old rope	3*d.* per lb.
other kinds of paper . .	9*d.* "
paper-hangings . . .	1*s.* per sq. yd.

These duties are nearly nominal, as with the exception of some particular kinds of drawing-paper, of which a small quantity finds its way, and paper-hangings, which are imported on account of the elegance of their patterns, all the paper used within the United Kingdom is of home manufacture.

PAPER MULBERRY. [BROUSSONETIA.]

PAPER NAUTILUS, or **PAPER SAILOR,** the popular English names for the Ναυτίλος (Nautilos) or Ναυτικὸς (Nauticos) of Aristotle (*Hist. Anim.*, iv. i.); *Argonauta* of Linnæus. This animal has been from the earliest periods an object of great interest to zoologists, on account of the romantic accounts of its sailor-like habits handed down to us from the antients—we need only refer to the accounts of Aristotle, Pliny, Ælian, Oppian, and others—and in consequence of the difference of opinion entertained with regard to the inhabitant of the shell by naturalists; some holding that the cephalopod found in it was a mere parasite, or, even worse, a pirate that had destroyed the legitimate owner and possessed himself of the shell; and others, that the animal was the lawful possessor and original constructor of it.

Among those who supported the former opinion were Lamarck, De Montfort, Ranzani, Poli, and De Ferrussac, to say nothing of Cuvier, the inclination of whose mind evidently was that the shell belonged to the animal, though he only designates the opinion of those who held the contrary as extremely problematical. Professor Owen appears to have been early inclined to this view of the subject. Dr. Leach, M. Rafinesque, M. de Blainville, and Mr. Gray, stand conspicuous among those who denied that the *Ocythoe* found in the shells of the genus *Argonauta* of Linnæus was the constructor of the shell.

The reasoning of those who held that the Argonautic cephalopod was the constructor of the shell appears to have been based upon the numbers found always fitting the shell, and, in the case of Poli and De Ferrussac, upon the supposed discovery of the animal *and shell* in the egg.

Those who opposed these views, or still doubted (and we confess that we were among the latter, thinking it highly probable that the animal would be found to bear a strong resemblance to *Carinaria*), were struck with the supposed anomaly which would be manifested if the cephalopod remains were the natural inhabitant. Evidence that the animal was not affixed to the shell had been given over and over again till it became largely cumulative, and had never been controverted. The animal had been seen to quit it when alive, and to fall out when dead by its own weight upon reversing the shell. How then was the shell to be secreted? Again, the specimens found in the greater majority of the shells were apparently females, and placed upon a great mass of eggs which filled up, at least, all the spiral part of the shell; and on these the body of the animal rested. An *Octopus*, nearly allied to *Ocythöe*, was caught in the Madras Roads with its ventricose body firmly imbedded in a ghee-bowl; and *Octopus arenarius* had been found in a *Dolium*. These and other facts, with which we will not weary the reader, seemed very powerful; but if any credence is to be given to the carefully conducted experiments of the lady whose valuable observations we shall now proceed to notice (and, after a strict scrutiny, we see no reason to view them with the slightest suspicion), the question *is* now set at rest, though it was *not* by Poli, who must, if this lady's experiments were correctly made and accurately reported, have been in error when he supposed that he saw the animal *and shell* in the egg.

In 1836 Madame Jeannette Power laid before the academy at Catania her 'Osservazione fisiche sopra il Polpo dell' Argonauta Argo,' in which, after a long and careful course of inquiry, she declared the following results:—1st, that the cephalopodous mollusk usually found therein is the constructor of the shell which it inhabits; 2nd, the clearing up of the doubts with regard to the first development of its eggs; 3rd, new facts respecting its habits.

In order to obtain the data from which Madame Power came to her important conclusions, she had cages constructed which were eight palms long and four broad, with a convenient interval (three or four lines) between the bars, which allowed the water to enter freely when placed in the sea, whilst the escape of the animal was prevented. Madame Power placed these cages in a shallow bottom in the sea near the citadel of Messina, where she could examine them undisturbed, and enclosed in them a number of living Argonauts, which she supplied every two or three days with food, consisting of naked and testaceous mollusks.

The following is this lady's description of the cephalopod of the Argonaut:—'It is furnished with eight arms, having on each two rows of suckers: the first two arms are more robust than the others, and should be so, because they serve as masts to support the sails, which, spread out, act before the wind as such. At the base they have on the inferior sides the double row of suckers, like the other six; but from the inferior row, at about an inch from the base in adults, a rather furrowed membrane begins to develop itself, which extends as far as the tip of the arm, and holding it bent, it can no longer execute the office of a rowing arm, but is employed by the animal as a sail. These sails are so large, that when turned backwards and pressed against the shell, they can entirely cover and protect it. Thus, as far as I can conclude, the true office of these sails is exactly that of keeping themselves applied to the shell at all times, in reserve for the moment when the animal, coming to the surface of the water, removes them, and spreading them, raises them as sails. In fact, the series of suckers of the sail-arms, when the membrane of the sails is wrapped about the shell, is placed exactly over the keel of it in such a manner that each sucker corresponds to each point in which the ribs of the shell terminate until they reach the two margins of the spiral.'

Madame Power compares these *sails* with the two wing-like lobes of the mantle of *Cypræa* [CYPRÆIDÆ, vol. viii. p. 254], not only from the manner in which they cover the shell, but because she has reason to believe that the formation of the shell is the result of a transudation from the membrane of the sails, the corrugations of which, in secreting the calcareous matter, may be the cause of the ribbed form of the shell.

This consideration, she remarks, may weigh in obviating the difficulties of those who cannot imagine how a shell containing a cephalopod should present no resemblance with the folds of the animal compressed within it. For if they would consider it the result of a calcareous deposition of the membrane of the sails, they would find not only the series of little points corresponding to the suckers, which shape themselves in the keel of the spiral, but an explanation of the deposition of the ribs, and of the smooth and paper-like condition of the shell.

The sail, when spread out, presents, according to Madame Power, a silvery surface, speckled with concentric circles of spots, with a black spot in the middle, surrounded with a beautiful gold colour; this and the vicinity of the suckers along the keel and the spiral assume a purple colour so vivid that it approaches that of the *Ianthina*. The mouth, the head, the bag, and the branchiæ, did not present Madame Power with any novelty beyond what had been already well described by naturalists, and which is common to the *Cuttles* and the *Calamaries*; but she makes two observations with regard to the funnel, which she believes to be new. 1st, that it fulfils the office of a pump or proboscis rather than that of a funnel, and that the animal employs it, when swimming with its arms on the surface of the water, as a helm, elongating it in front of the widest part of the shell, at the same time that the spiral serves as a prow.*

'Reflecting,' says Madame Power, 'on the delicacy and fragility of the shells, and wishing to trace the cause of their being so rarely seen broken, I determined to touch one whilst its poulp or animal was within; and taking it dexterously between my fingers, to learn what degree of flexibility it would admit, I discovered that it was extremely elastic, so much so as to admit of the two extremities of the great curve being brought in contact without breaking; and indeed shells so fragile ought to possess this flexibility, in order that they might not be continually liable to be broken in pieces by the restless and uninterrupted movements of their poulps, as well as by the shocks which they would be likely to suffer in the depths during a stormy sea. In this case it would prove very unfortunate for them, as they are not capable of forming an entire new shell.'

'Having ascertained the flexibility of the shell whilst the living animal was within, I immersed some empty ones which had been exposed to the air for some time in fresh water, and, at the end of three days, found them as pliant and flexible as at first.'

'As regards the connection between the animal and the shell in which it is lodged, I have not found any ligament or muscle which connects them; while the pot is simply held by the turning of the end of the spiral, from which it may be easily separated; and it appears that the tight adhesion of the sac against the internal surface of the ribs of the shell is sufficient to hold it attached. Moreover the external superposition of the sail-arms keeps the shell firmly upon the poulp.'

Habits, &c.—Madame Power states that *Argonauta Argo* in its natural state is to be found in the neighbourhood of Messina, and even in the port, almost all the year through, in larger or smaller numbers. Their true season she considers to be autumnal, or in the months of September, October, and November. It may be, in her opinion, either because the current brings them at that time, or that food is more plentiful, or because it may be the season of their fecundation. They are seen in the most muddy parts of the port, and where the anchored boats lie thickest. When the Argonauts swim on the surface of the water, if they observe any person, they fold the sail-arms over the shell and stow the swimming-arms inside it; then they sink to the bottom. If they are beneath the surface, they eject ink, like other cephalopods, to make the water turbid, thus gaining time to hide themselves in the mud.

Those in the cage, when closely pursued, would, after spending their ink, spirt out water from the tube, and then shrink into the shell, which was covered with the sails. At first the appearance was silvery, but instantly afterwards a purple colour would spread along the suckers over the whole of the keel and spiral, and successive circles of spots would show themselves upon the two surfaces.

During calms and when the water was quiet, they would, if not conscious of being observed, exhibit their many beauties, rowing along, their full sails tinged with elegant colours, resting the extremities of the sail-arms on the two sides of the shell or embracing the shell with them. Sometimes, when pressed by hunger, they would come almost to the surface of the water, and when Madame Power offered them food, they would snatch it out of her hands and greedily devour it.

Reproduction; Formation of the Shell by the young Argonaut; Repair of Fractured Shell.—Madame Power appears to have approached this part of the subject with the impression that she was only about to repeat the experiments of the great Poli on the eggs of the cephalopod, in which he supposed that he had discovered the embryo of the shell; but she obtained very different results. Madame Power repeated the experiments of Poli in the company of Dr. Anastasio Cocco of Messina and other persons, but nothing more was found than a group of eggs in each individual, similar to millet-seeds, perfectly white and transparent, attached by filaments of a brilliant gluten to a common stem of the same substance. Three days after the first observation, on visiting an Argonaut, little poulps were found in the shell of the parent, developed, but without shell, and resembling worms, having at the inferior extremity a spot of a brown colour, with some smaller spots disposed laterally. These, when examined by the microscope, were considered to be the viscera of the animal. After the three days the young poulps began to exhibit bud-like prominences, with two rows of obscure points, which were the rudiments of the arms and suckers. The other arms began to be distinguishable some days after the sailing-arms, and on the sixth day they had already formed the first *lamina* of the shell, which was exceedingly soft, yielding to the least pressure of the finger. The eggs are attached to the interior of the spire, and when excluded remain between the roof of the spire and the mantle of the mother. From these observations Madame Power concludes that the newly-born poulp *has no shell*. The observations of Poli therefore do not correspond with the experiments made by Madame Power; and the lady adds, with characteristic modesty, 'If I were not speaking of so celebrated a man, I should venture to say that the internal membrane of the egg was mistaken by him for the supposed rudiment of the shell.'

Madame Power, wishing to discover whether the little poulp could, without extraneous aid, begin to work the structure of its shell, or whether the parent assisted in the original formation, cautiously cut off the spire of divers Argonauts at the time of their fecundation. In the direction of its axis she found in one a little new-born poulp rolled up near the apex. Upon attentive observation she perceived that between it and the bottom of the spire of the parent shell there was a thin membrane, disposed in the same form as the curve of the spire, and fitted to the rolled-up little poulp, as if the gluten in which the whole infant mollusk was embedded, pressed between it and the end of the spire, became consolidated into a fine membrane in the same form as the spire, and embraced the young poulp.

In September, 1835, Madame Power enclosed in her cage some Argonauts at the time of their fecundation, taking care to examine them every fourth day carefully, for their irritability is such that they die if handled much. They were placed in a basin, and the observer was so posted that they could not see her.

On the 14th Madame Power found in one of the shells a little poulp fourteen lines long. Other shells were searched, and, in some, little poulps were found; in others none. On the 18th two parent poulps were dead. In the shell of that wherein she had first seen the little poulp she found that it had already passed into the spire. On the 24th, upon examination of this same shell, the little poulp was found already covered with its thin shell, which was 3½ lines in length. This little animal appeared to be completely formed, and its shell had the form of the spire in which it had been framed.

All the experiments made by Madame Power had the same results; her inference is, that the young Argonaut, when excluded from the egg, is naked; that it is progressively developed in the end of the spire of the parent; and that after a certain period it goes on forming the shell.

---

* [illegible]

As far as Madame Power has observed, not more than two or three eggs develop themselves at the same time; and when the young have grown to the length of nine lines, they successively inclose themselves in the spiral of the parent, where the other arms are thrown out in the manner of buds. The young one takes three days to arrive at the length of nine lines, and four in the spiral to develop itself. The parent retains the young one three more days under her, and then ejects it from the shell.

An attempt was made by Madame Power to produce the development of the eggs as far as the production of the young poulp, without the aid of the mother, by suspending them in a fine linen bag in sea-water, which was changed thrice in the day. This attempt failed; the eggs swelled indeed, but it was the tumidity of putrefaction.

Madame Power concludes from this experiment that the glutinous material in which the young are enveloped in the spire of the parent conduces to their development; and this material being evidently a parental secretion, it may be said that without her aid the eggs could not be developed, and the young shell could not have its foundation laid in the end of the spire.

We shall now let Madame Power speak for herself. 'In spite of these successful experiments in favour of the shell being the property of the poulp of the Argonaut, I was anxious to be assured of the fact in a manner not hitherto attempted by others. "If the Argonaut," said I, "constructs its own shell, it ought to be able to repair fracture." Although Signor Ranzani had said that it was not to be believed that these poulps of the Argonaut should be so ill provided with means necessary for the preservation of their existence, that if the first habitation should be broken or lost, they cannot construct another; still I thought, from his mode of expression, that he had never himself made experiments in proof of this. Moreover I, who have made experiments on a hundred of these mollusks, have found that, when they have lost their shell, they are incapable of constructing another, and die;[*] but I broke in several places the shells of twenty-six individuals, and, to my great satisfaction, found, after thirteen days, the fractures healed in all the survivors, which were not more than three. The newly-secreted portion was stouter than the uninjured part of the shell, but not so white; it looked also a little rough and disturbed, neither did it present the usual risings, and, instead of ribs, it had some longitudinal furrows. Being desirous of observing in what manner the animal operated in repairing the broken shell, I took one the day after the first experiment, and found that the aperture was covered by a thin glutinous lamina, which, somewhat in the manner of a cobweb, unites the two margins of the broken shell. The next day the lamina was, to a certain degree, thickened and more opaque, till, at the expiration of ten or twelve days, the new piece had become quite calcareous. Whilst the Argonaut was in the act of mending the fractures in its shell, I am quite sure that it applied the sails to the shell and wrinkled them upon it, and by this movement I considered that the glutinous secretion which finally became calcareous was deposited.'

So far Madame Power has shewn that the Argonaut has the power of repairing fractures in the shell, like other *Testacea*, though not exactly by the same means; but she noticed another power, which she states that, as far as she knows, has not been observed in other testaceans. She found that whenever the animal which is going to repair its habitation can find pieces of other Argonaut shells, it takes, by means of its sail-arm, a fitting piece of broken shell and holds it in the fractured place, till it has secreted the material necessary for the firm attachment of the fragment, thus saving the expense and trouble of a secretion for supplying the whole area of the fractured aperture. 'After such a series of experiments,' says Madame Power, 'it seems to be sufficiently proved that the poulp of the Argonaut is the constructor of the shell in which it lives, and out of which it cannot exist long.'

Now though there may appear in the account of these experiments evidence of their having been drawn up by one not deeply versed in zoology, there is an air of truth and sincerity about them that makes them to us as valuable at least as any that could have been the result of the inquiries of a more learned observer. Madame Power indeed has, in our opinion, come to a somewhat hasty conclusion that these animals are hermaphrodites, because all those that were examined by her (more than a hundred) were furnished with eggs; but this inference is evidently not deemed conclusive by her, for she states her intention of making careful anatomical researches on this subject, which she had not enjoyed the opportunity of making when she wrote.

We have heard some stress laid on the mistake made by Madame Power, when she, at first, fancied that the parasitic *Hectocotylus* of Cuvier was the young of the Argonaut. We think but little of it; and indeed the very information that it was a parasite, which Professor Owen, who detected the genus, communicated to her, seems to have made her more vigilant. In a second paper, with the title of 'Nuove Osservazione sulle Uovo del Polpo dell' *Argonauta Argo*,' by the same lady, after alluding to this mistake, she makes the following observations on the progressive development of the young one. The egg was first white and transparent; no structure was discernible in it. After fifteen days it presented spots of a beautiful red. In ten days more the poulp could be discerned through the epidermis of the egg. Then the poulp began to break through that involucrum, and to the naked eye presented an elliptical form, with the eyes and mouth, and a very transparent membrane which forms the mantle. Towards the mouth some small and almost imperceptible filaments were observed, which Madame Power supposed to be the rudiments of the branchiæ. The poulps were now naked, but in twelve days from that time, on visiting them again, some were found which had already formed their shell, and the parent retained them and nourished them with her gelatinous secretion, as Madame Power had already stated in her memoir published in the 12th vol. of the 'Transactions of the Giœnian Academy.'

Captain Philip Parker King, R.N., during his well known voyage, met with some specimens of *Argonauta* in a rather curious way; and though he expresses his opinion with much modesty, it is plain what the inclination of that opinion was.

'On our passage from Santos to St. Catherine's, in lat. 28° south, we caught,' says Captain King, 'a dolphin (*Coryphæna*), the maw of which I found filled with shells of *Argonauta tuberculosa*,[*] and all containing the *Octopus Ocythöe* that has been always found as its inhabitant. Most of the specimens were crushed by the narrow passage into the stomach, but the smaller ones were quite perfect, and had been so recently swallowed that I was enabled to preserve several of various sizes containing the animal. To some of them was attached a nidus of eggs, which was deposited between the animal and the spire. The shells varied in size, from two-thirds of an inch to two and a half inches in length; each contained an octopus, the bulk and shape of which was so completely adapted to that of the shell, that it seemed as if the shell increased with the animal's growth. When so many learned naturalists have differed so materially as to the character of the inhabitants of the argonauta, it would be presumption in me to express an opinion; I therefore merely mention the fact, and state that in no specimen did there appear to be any connection between the animal and the shell.' (*Voyages of the Adventure and Beagle*, vol. i., p. 106.) We had an opportunity of examining the specimens above alluded to soon after Captain King's return, and they bore out in every particular the description given by him.

M. d'Orbigny (*Voyage dans l'Amérique Méridionale*) came to a conclusion in favour of the animal being the constructor of the shell, and consequently against the parasitic theory, from observations made by him on *Argonauta hians*.

In 1837, M. Rang, on his return from Algiers, where he had been observing these animals, had an interview with M. de Blainville, who had then the observations which Madame Power had just made in his hands; and, in April of that year, M. de Blainville read his elaborate Report, and afterwards published it, with additional dissertations, in the form of a memoir or letter, in the third number of the *Annales Françaises et Etrangères d'Anatomie et de Physiologie*. His arguments in favour of parasitism appear to be based on the following data:—1, That the same species of cephalopod is not always found in the same species of shell. 2, That the natural position of the animal in the shell varies, the back of the animal being sometimes next the outer wall, of the shell, sometimes near the involuted spire. 3. That the animal does not occupy the posterior part of the shell. 4. That the form of the animal and of its parts offers no resemblance or analogy with the shell. 5. That the shell is too opake to have permitted the influence of light in the development of the coloured pigment in the mantle of the cephalopod of the argonaut. 6. That it is very far from being true that the argonaut-shell possesses the flexibility and elasticity requisite to harmonise with the locomotive and respiratory movements of the animal. 7. That the animal suffers no appearance of inconvenience when deprived of its shell. 8. That a cephalopod has been discovered in the Indian seas like that which inhabits the argonaut, but without a shell. These data are designated by Professor Owen, to whose observations we shall presently advert, as false facts, with the exception of the third, which is only partially false, being true when stated with reference to the more mature animal only. The other arguments of M. de Blainville are noticed by Professor Owen as founded on undoubted or admissible facts; but the Professor denies the conclusions drawn by M. de Blainville.

---

[*] Aristotle speaks of the shell as being like a hollow pecten (κτεις), and not naturally adherent to the polypus. He also states that it feeds very frequently near the land, so that it is thrown by the waves upon the sand, when the shell slipping from it, it is caught, and dies on land. (*Hist. Anim.*, iv. 1.)

[*] *A. rufa* of Owen.

M. Sander Rang in consequence of the appearance of M. de Blainville's memoir or letter, published in Guerin's *Magasin de Zoologie* a very interesting paper under the title of 'Documents pour servir à l'Histoire Naturelle des Céphalopodes Cryptodibranches.' In this memoir M. Rang's observations are confirmatory,—1, of Madame Power's statement that the siphon is applied to the part of the shell opposite the involuted spire; 2, of the accuracy of her description of the relative position of the so-called sails of the Argonaut with reference to the shell; 3, of her discovery of the faculty possessed by the animal of repairing the shell, and many other points.

No one will refuse to M. Rang the acknowledgment that he is not only a very accurate observer, but that he is well versed in the natural history and anatomy of the mollusca generally; so that here at least no doubt can be thrown on the observations.

M. Rang however appears to have been staggered by the pertinacity of M. de Blainville; for after all, he sums up by declaring himself to be 'in the most complete state of uncertainty.'

In February, 1839, a highly interesting and valuable series of specimens of the Paper Nautilus (*Argonauta Argo*) consisting of the animals and their shells of various sizes, of ova in various stages of development, and of fractured shells in different stages of reparation, were exhibited to the Zoological Society of London, and commented on by Professor Owen, to whom they had been transmitted for that purpose by Madame Power, who had formed the collection in Sicily, in 1838. In the course of his comments the Professor went at large into the subject, and in addition to the observations above alluded to with regard to the alleged false facts and admissible facts whereon M. de Blainville had founded his reasoning, combated at great length, and, in our opinion, with signal success, the arguments of those who adhered to what may be termed the parasite opinion; and recapitulated as follows the evidence which, independently of any preconceived theory or statement, could be deduced from the specimens then on the table.

1. The cephalopod of the argonaut constantly maintains the same relative position in its shell.

2. The young cephalopod manifests the same concordance between the form of its body and that of the shell, and the same perfect adaptation of the one to the other as the young of other testaceous mollusks.

3. The young cephalopod entirely fills the cavity of its shell; the fundus of the sac begins to be withdrawn from the apex of the shell only when the ovarium begins to enlarge under the sexual stimulus.

4. The shell of the Argonaut corresponds in size with that of its inhabitant, whatever be the differences of the latter in that respect. (The observations of Poli, of Prevost, of Rang, and of Owen, are to the same effect.)

5. The shell of the Argonaut possesses all the requisite flexibility and elasticity which the mechanism of respiration and locomotion in the inhabitant requires; it is also permeable to light.

6. The cephalopod inhabiting the Argonaut repairs the fractures of its shell with a material having the same chemical composition as the original shell, and differing in its external properties only in being a little more opake.

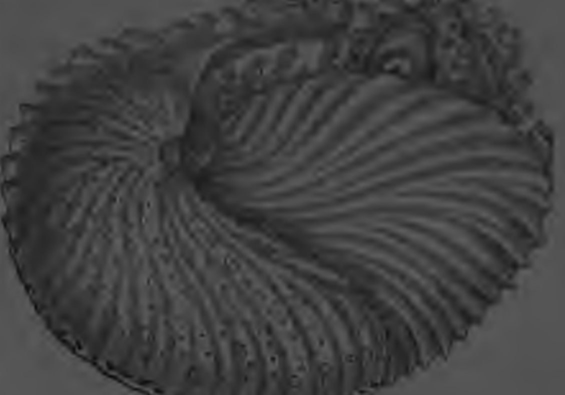
7. The repairing material is laid on from without the shell, as it should be according to the theory of the function of the membranous arms as solidifying organs.

8. When the embryo of the Argonaut has reached an advanced stage of development *in ovo*, neither the membranous arms nor shell are developed.

9. The shell of the Argonaut does not present any defined nucleus.

Professor Owen concluded a most elaborate commentary by stating that he regarded the facts already ascertained to be decisive in proof that the cephalopod was the true fabricator of the shell; and thus, in our opinion, is set at rest—principally by the experiments of Madame Power—a question which had divided the opinions of zoologists from the time of Aristotle, who left the subject with the following acknowledgment: 'But as touching the generation and growth of the shell, nothing is as yet exactly determined.'*

M. Rang's account of the locomotion of *Argonauta Argo* is most interesting. When the animal was at rest and contracted within its shell, it exhibited the appearance figured below.



Argonauta Argo contracted within its shell, and the membranes of the sail-arms partially covering it. The eggs were never seen by Mr. Rang in the place where they are represented, but much more within the opening. (Rang.)

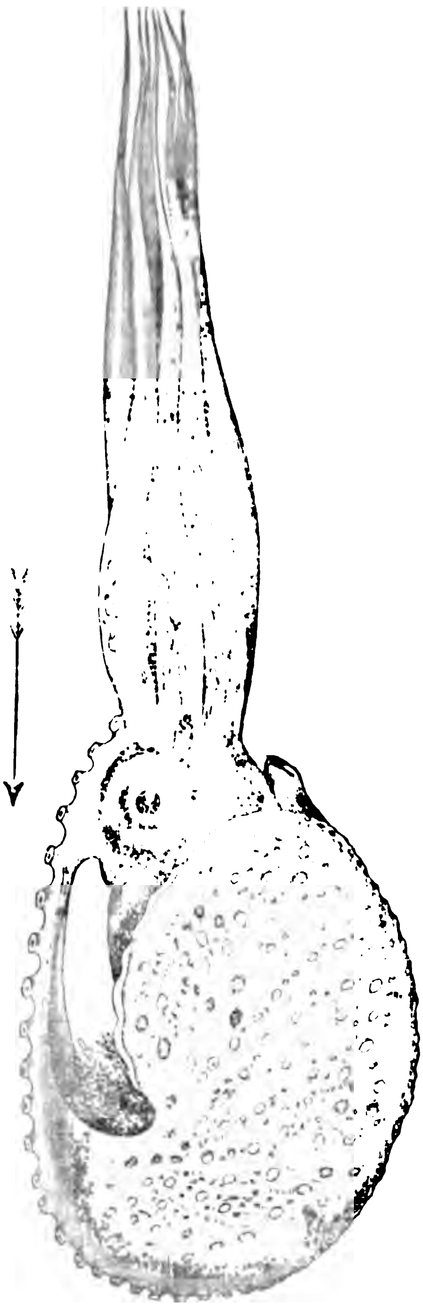
'To return to the description of our poulp,' says M. Rang, 'which we left contracted within the argonaut-shell, and watching, with an attentive eye, what took place around it, we saw it extending itself from out its shell, and protruding six of its arms; then it threw itself into violent motion, and travelled over the basin in all directions, often dashing itself against the sides. In these different movements the body leant a little towards the anterior part of the shell; and the long slender arms, very much extended and collected into a close bundle, were carried before it, as well as the tube, which showed itself open and protruded. The locomotion was effected in the ordinary manner of poulps, the movement being backwards by means of the contraction of the sac and the expulsion of water through the siphon. The disposition of the animal and shell is the most favourable for accelerating the motion of the creature. The lightness of the shell,—its narrow and keeled form,—its width, which is smallest at the part presented first for cleaving the water—the membrane smoothing over all inequalities of the shell—the bundle of arms extending behind so as to offer the least possible resistance,—the two arms stretched like a bridge over the cavity where the eggs are, as if to throw off the water from that cavity;—all these adaptations concur to facilitate the gliding of the animal through the medium in which it is to move.'

M. Rang thought that he perceived in the movements of the animal, when in open water, that it had its back uppermost, and consequently the tube below; but he did not constantly see it so: he observed it however with more certainty in specimens of poulps whose arms had been deprived of their membranes.

The animal which they had been watching, as above described, fatigued by its efforts in a confined space, and perhaps injured by the shocks which it had sustained in coming in contact with the side of the basin, allowed itself to sink to the bottom, and half contracted itself in order to take repose; soon after which it exhibited another and unexpected

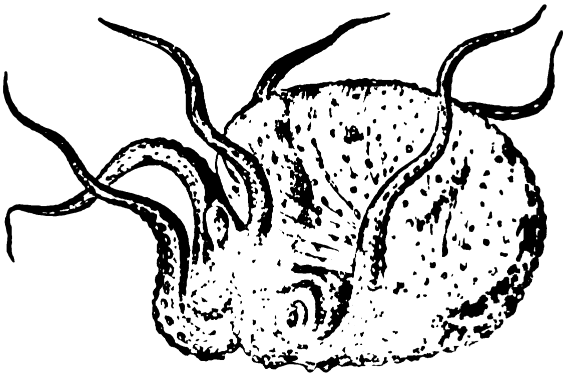
---

* Hist. Anim., iv. 7; where a detailed account of the locomotion of the Nautilus, its sailing, &c., is given.



Disposition of the shell and animal when moving through the water in the direction of the arrow. (Rang.)

spectacle. Fixing some of the acetabula of its fore-arms upon the bottom of the basin, it erected itself upon its head, spreading out its disc, and carrying the shell straight above it in the normal position of the shells of gastropods; then, beginning to crawl, it presented the appearance of a pectinibranchiate mollusk, as M. Rang had remarked in the note to the Academy of Sciences. Half drawn back into its shell, the animal appeared to crawl upon its disc, the palmatures of which were a little raised to follow the movements of its arms. The body was hidden in the shell; the siphon placed in the anterior part of it was turned forwards; the arms which were at liberty were very much protruded and twisting round, two before and two on each side: the base of the two large arms seemed to prolong backwards the locomotive surface, and then rising along the keel, they again covered it with their large membranes, as when the poulp was swimming in deep water. 'Thus,' continues M. Rang, 'this mollusk, at once pelagic and littoral, presents a most singular anomaly; when it swims at the surface of the water, having its ventral part lowermost, and when it crawls along the bottom having it, on the contrary, uppermost; things which are completely contrary to what we see among the pelagic mollusks on the one hand, and the littoral mollusks on the other.'



Argonauta Argo moving on its head at the bottom. (Rang.)

The progress of the animal, when moving as last above represented, was slow, and it worked itself onwards like the gasteropodous mollusks. M. Rang remarks that the reptation was only apparent; for the suckers really caused the motion.

When the poulp was at the point of death, it drew in by slow degrees its large arms and their membranes, and contracted them upon themselves and all the other arms, so as to obstruct the opening of the shell. At this moment the shell was moved, and the poulp separated itself from it, not voluntarily but accidentally, for it no longer held it in any way. It appeared at first to become a little reanimated, made some movements in the basin upon its head, then fell from weakness, and soon died. All this passed in less than ten minutes.

Translations of the memoirs of Madame Power and of M. Rang will be found in *The Magazine of Natural History*, vols. i. and ii., *N. S.*

In the Dibranchiate Octopods, generally, the ovary is a spherical sac with thick parietes. In the *Argonaut* the oviducts are two in number, long and convoluted, furnished with glandular coats throughout, but without partial enlargements: there are no separate nidamental glands. These oviducts are continued by a short common passage from the ovary and form several convolutions before they ascend to their termination, which is the same as in *Octopus*; but they differ from *Eledone* and *Octopus*, in having no glandular laminated bodies developed upon them: the minute ova of the Argonaut are consequently connected together by the secretion of the lining membrane of the long and tortuous oviducts. These ova occupy a greater or less proportion of the bottom of the shell; they are oval, about half a line in length before the development of the embryo has commenced, and are connected in clusters by long filaments. In the museum of the Royal College of Surgeons is a preparation (No. 2657 B., *Physiological Series*) of an Argonaut (*Argonauta rufa*, Owen) with the ventral parietes of the abdomen and the gills removed, to show the female organs of generation. The ovary is lodged at the fundus of the visceral sac. The two oviducts, which are contin from its posterior part, are convoluted at first, and then advance straight forwards to the base of the funnel. (vol. iv., Owen.)

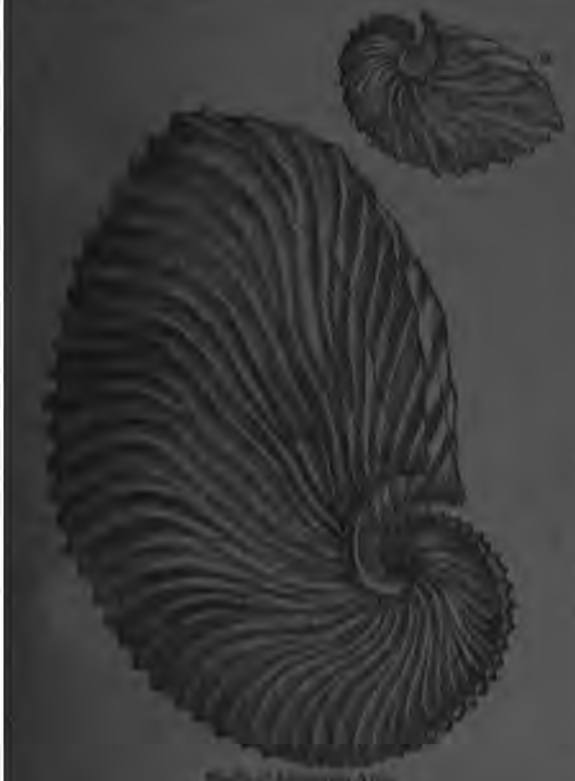
From the time of Aristotle the Cephalapods have been known to be diœcious with reference to the sexual organs, and there appears to be a great majority of females. We are not aware of a single instance of a male *Argonaut* having been taken: it remains to be proved whether this arises from the comparative activity of the males, their relatively small numbers, or from their not being furnished (which some have thought to be not an impossible case) with shell at all.

Place in the System.—The natural situation of *Argonauta* appears to be that assigned to it by Professor Ow namely in the Testaceous family of the tribe *Octop* Mr. Owen's second order of Cephalopods—*Dibranchia*

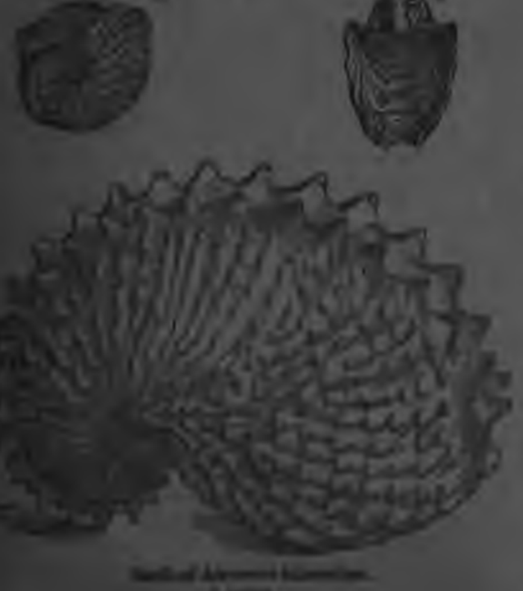
Generic Character.—*Body* oblong, rounded; mantle adhering posteriorly to the head; first or dorsal pair of arms dilated and membranous at the extremity. *Funnel* wit a valve, but articulated at its base by two ball-and socket joints to the inner sides of the mantle. *Branchial hearts* with fleshy appendages. No internal horny or testaceous rudiments; but an external, monothalamous, symmetrical shell, containing, but not attached to, the body of the animal, which also deposits its eggs in the cavity of the shell. (Owen.)

Geographical Distribution.—The seas of warm latitudes, both littoral and pelagic. Captain King's specimens above noticed (three of which by the way had no eggs in the shells) were taken from the stomach of a Dolphin caught upwards of six hundred leagues from land.

Several species are already known; and the specific characters rest in great measure upon the tuberculations and rib-like elevations on the outside of the shell and on the breadth of the keel. The absence or presence of projecting pointed processes at the sides of the aperture near the spire part cannot safely be relied on as a specific character: we possessed both broad-keeled and narrow-keeled specimens (now in the British Museum), in which the projecting process was present on one side of the shell and absent on the other.



Shell of Argonauta Argo.
[illegible]



Shell of Argonauta tuberculata.
[illegible]

The fossil genus *Bellerophon* is placed by Professor Owen with *Argonauta* in the family of Testaceous Octopods. (BELLEROPHON.)

PAPER HANGINGS, a term applied (somewhat incorrectly) to the stained paper pasted against the walls of apartments, &c. The word 'hangings' was originally and properly applied to the woven or embroidered tapestry with which the walls of elegant rooms were covered. From the time necessary for their production, these were too costly for any classes but the wealthy. About 200 years ago however, a mode was devised of printing or painting a pattern on sheets of paper, and pasting them against the walls of a room; these are 'paper-hangings,' and they have greatly contributed to the comfort and cleanliness of domestic apartments.

There are three modes of producing the required device. 1. Wooden blocks are carved, representing in relief the *outlines* of the figure; an impression is taken from these blocks, and the device is completed by painting with a pencil. 2. A sheet of paper, leather, tin, or copper, is cut out into the required device, and laid on the paper to be stained; a brush, dipped in a coloured pigment, and worked over the surface of the perforated plate, conveys the pigment through all the perforations, and forms a pattern on the paper. 3. A block is carved for each of the colours to be employed, and an impression from all the blocks in succession fills up the design on the paper. The first of these modes is too slow and costly for ordinary use; the second produces imperfect outlines, and is now chiefly employed (under the name of *stencilling*) to paint a pattern on the plaster walls of a room, without using paper-hangings; the third, which is the mode almost exclusively employed at the present day, is described here.

The paper is printed in pieces twelve yards long, and to produce these it was formerly necessary to paste sixteen or eighteen sheets of paper together at the edges. But machine-made paper now allows the paper-stainer to procure the whole length in one piece. A 'piece' is laid out on a long bench, and the 'ground-colour' applied, consisting of pounded whiting tinted by the addition of some pigment, and liquefied by the aid of melted size; this is laid on with large brushes. When the paper is dry, it is ready to receive the print. Let us suppose the pattern to contain three colours,—red, dark green, and light green. Three blocks are carved in hard wood, the uncut parts (as in a common wood-block) representing the device; each block is intended for one colour only; and care is taken that all three shall combine their devices properly, when printed. The three pigments being mixed with melted size, in separate vessels, one of them (say red) is spread with a brush on a woollen frame covered with leather or flannel; the proper block is laid face downwards on the wet paint, takes up a layer of it, and imparts it to the paper, on which it is immediately pressed. Another similar impression is made adjoining the first; and so on, till the whole 'piece' has been printed with the red device. When dried, the paper goes through the same process a second time, with the substitution of a different colour and a different block from those before used. A third process with the other shade of green finishes the printing. Each block is furnished with small pins at the corners, by the aid of which the successive impressions are made to correspond properly. As many as seven or eight colours are sometimes employed in one pattern, and generally speaking there must be as many blocks as there are colours.

Some paper-hangings have a glossy or 'satin' ground. To produce this, a ground of satin white, properly tinted, is laid on; this ground is then rubbed with powdered French chalk worked by means of a brush, until a gloss is produced. After this the printing proceeds as usual. These 'satin' papers sometimes receive an additional beauty, by being passed between two slightly heated rollers, one of which has an engraved pattern in imitation of watered and figured silk, &c.: this pattern is thus imparted to the paper. *Flock* papers are those in which a portion of the pattern somewhat resembles woollen cloth. When the proper ground-colour has been applied, the device is printed, not with a coloured pigment, but with japan gold-size, and on this gold-size is sprinkled the flock, consisting of fragments of woollen cloth cut into a sort of down and dyed. The flock adheres to the gold size and can easily be brushed off the other parts. Sometimes flocks of two or three colours are employed; these are laid on at separate times. *Striped* papers are sometimes produced in a singular manner. The colour (rather more liquid than in other cases) is contained in a trough having parallel slits in the bottom. The paper is made to pass quickly under the bottom of the trough, by means of a revolving cylinder, and thus obtains a deposit of colour in parallel lines, through the slits in the bottom of the trough. By a modification of this method is produced what is termed a *blended* ground. A trough, containing many distinct cells, is filled with various tints of any given colour, one tint to each cell. A long narrow brush being dipped into all these cells, takes up a portion of each tint, which it applies to a roller; from the roller the pigment is transferred to a revolving brush, and from the brush to the paper. Thus is produced a blended or shaded ground, which afterwards receives any desired pattern.

Bronze or imitation gold-powder is frequently applied to papers. A device being printed in japan gold-size, the powder is lightly rubbed over the paper, and adheres to the gold-size. The remainder of the pattern is commonly printed in colours. In some papers, leaf-gold, silver, or copper is applied to a portion of the pattern: this is a slow and expensive process. Some papers, in order to bear washing or cleaning, are printed with colours mixed with oil or varnish instead of size.

The modes of cutting the pieces of paper and pasting them against a wall are too obvious to need mention here.

A recent change in the duty charged on all kinds of paper, is likely to have considerable effect in extending the use and improving the manufacture of paper-hangings. The duty on the paper itself has been reduced from 3*d.* to 1½*d.* per pound; while the additional duty of 1¾*d.* per square yard of paper-hangings, considered as such, has been wholly repealed. 'The reduction of price it has occasioned, has enabled a much larger class of persons to get their apartments papered; and it will in this way be productive not only of a great additional demand for paper, but of a great increase of comfort and cleanliness.' (M'Culloch.) Paper-hangings are indeed now made for so low a price as five-pence for the piece of twelve yards.

With regard to the *patterns* of paper-hangings, we may remark, that the attention which has lately been given to the promotion of the arts of design will probably lead to much improvement in the devices for paper-hangings, as well as for other ornamental productions. A few years ago Mr. Loudon suggested that 'an instructive *natural history paper* for cottages and the walls of nurseries and schoolrooms might be formed, by printing figures of all the commoner and more important plants and animals, with the scientific and popular names beneath them; each plant or animal being surrounded by lines, so as to appear either in frames or as if painted on the ends of stones and bricks.' An ingenious suggestion on the subject of 'intellectual paper-hangings' has recently been made in No. 504 of the 'Penny Magazine.'

PAPHLAGO'NIA (Παφλαγονία), a province of Asia Minor, also called Pylæmenia according to Pliny (vi. 2), was bounded on the north by the Euxine, on the south by the part of Phrygia afterwards called Galatia, on the east by Pontus, and on the west by Bithynia. It was separated from Bithynia by the Parthenius (Olu or Bartan), and from Pontus by the Halys (Kizil-ermak), which was also its eastern boundary in the time of Herodotus (i. 6, 72).

Paphlagonia is described by Xenophon (*Anab.*, v. 6, s. 6) as a country having very beautiful plains and very high mountains. It is traversed by two chains of mountains, running parallel to one another from west to east. The higher and more southerly of these chains, called Olgassys by Ptolemy, is a continuation of the great mountain-chain which extends from the Hellespont to Armenia, and was known to the antients under the names of Ida and Temnon in Mysia, and Olympus in the neighbourhood of Brusa. [ANATOLIA, p. 493.] Strabo (xii., p. 561, 562) however appears to give the name of Olgassys to the chain of mountains in the northern part of Paphlagonia, on which the Paphlagonians had built many temples. The country between these two chains of mountains is drained by the Amnias (Kara-su), which flows into the Halys. There were several small streams which flowed from the mountains in the north of Paphlagonia into the Euxine, but the only river of importance besides the Amnias and Halys was the Pathenius, which is said by Xenophon to be impassable. (Xen., *Anab.*, v. 6, s. 9.) In the neighbourhood of peiopolis, in the central part of the province, was a mountain called Sandaracurgium, where, according to Strabo (xii., p. 562), sandaraca was obtained in mines, which were worked by criminals, who died in great numbers in consequence of the unhealthiness of the labour. The sandaraca spoken of by Strabo was probably the same as sinopis, which was a kind of red ochre, obtained by the Greeks from Sinope, from which place it derived its name.

The Paphlagonians are said by Homer (*Il.*, ii. 851, 852) to have come to the assistance of the Trojans under the command of Pylæmenes from the country of the Heneti. This mention of the Heneti in connection with the Paphlagonians seems to have puzzled some of the antient writers. Several explanations of the passage were given; but the one which appeared most probable to Strabo (xii. 544) was that the Heneti were a Paphlagonian people, who followed Pylæmenes to Troy, and, after the death of their leader, emigrated to Thrace, and at length wandered to Italy, where they settled under the name of Veneti. Pliny (vi. 2) also connects the Heneti of Homer with the Veneti of Italy upon the authority of Cornelius Nepos; but few modern critics will be disposed to attach much credit to a rambling story of this kind, which seems to have arisen merely from the similarity of the two names.

The Paphlagonians were subdued by Crœsus. (Herod., i. 28.) They afterwards formed part of the Persian empire, and were governed by a satrap in the reign of Darius Hystaspis (Herod., vii. 72); but they appear in later times, like several other nations in the remote parts of the Persian empire, to have been only nominally subject to the king of Persia. On the return of the Ten Thousand, we find that they were governed by Corylas, who does not appear to have been a satrap (ἄρχων, Xenophon calls him, *Anab.*, vi. 1, s. 2), and who did not hesitate to afford assistance to the Greeks. After the death of Alexander, Paphlagonia, together with Cappadocia, fell to the share of Eumenes. (Diod. Sic., xviii. 3.) It subsequently formed part of the kingdom of Pontus; but after the conquest of Pontus by the Romans, it appears to have been allowed to have kings of its own, the last of whom was Deiotarus, the son of Castor. (Strabo, xii. 562.) Under the early Roman emperors it did not form a separate province, but was united to the province of Galatia till the time of Constantine, who first erected it into a separate province.

The principal town of Paphlagonia was Sinope (Sinoub), a colony of the Milesians (Xen., *Anab.*, vi. 1, s. 15), which was said to have been founded by Autolycus, a companion of Jason. It was built upon a peninsula, and was for many centuries one of the most flourishing commercial towns on the Euxine. In the time of Strabo, when its trade had greatly decreased, it was a place of considerable importance. It was very strongly fortified, and possessed many handsome public buildings. The soil in the neighbourhood was very fertile, and the inhabitants were accustomed to catch off the coast great numbers of pelamydes, a species of tunny-fish. Sinope maintained its independence till the second century before the Christian æra, when it was taken by Pharnaces I., king of Pontus, and annexed to the kingdom of Pontus. Mithridates the Great, who was born there, made it the capital of his dominions, and adorned it with many public buildings. During the war which he carried on with the Romans, it was taken by Lucullus. It was subsequently made a Roman colony. Diogenes the Cynic was born in this town. (Strabo, xii. 545, 546; Plin., vi. 2.)

West of Sinope on the coast were—Harmene, off which the Ten Thousand anchored for five days (Xen., *Anab.*, vi. 1, s. 15-17); Abonteichos, afterwards called Ionopolis (Ainabal), which is described by Strabo (xii. 545) as a small town, and was the birthplace of the impostor Alexander, of whom Lucian has given us an account; and Amastris (Amasera), formerly called Sesamus, under which name it occurs in Homer (*Il.*, ii. 853). Amastris was built upon a peninsula, on each side of which there was a harbour. It received the name of Amastris from Amastris, the wife of Dionysius, the tyrant of Heraclea, and the daughter of Oxyathras, who was brother of the Darius conquered by Alexander. She peopled the new town with the inhabitants of Sesamus, Cytorus, Cromnum, and Tium. (Strabo, xii. p. 544.) Amastris is mentioned by the younger Pliny (*Ep.* x. 99) as a beautiful town in his time.

The principal towns in the inland part of Paphlagonia were—Pompeiopolis, on the river Amnias, which was built by Pompey after his conquest of Mithridates; and Gangra, on the confines of Galatia, which was the residence of D tarus, the last king of the Paphlagonians. (Strabo, xii. 541.)

PAPHOS. [Cyprus.]

PA'PIAS, one of the early Christian writers in the Greek language, was bishop of Hierapolis in Asia at the beginning of the second century. According to Cave, he flourished in the year 110, according to others in 115 or 116. He wrote five books, entitled 'An Explanation of the Words (or Oracles) of the Lord,' which are now lost. In a passage of this work which is quoted by Eusebius, Papias professes to have taken great pains to gain information respecting Christianity from those who had known the apostles, and some remarkable statements of his respecting the apostles and evangelists are still preserved. According to Irenæus, he was himself a hearer of John and a companion of Polycarp. He is said by Eusebius to have been a Millennarian, and a man of little mind, 'as appears,' says Eusebius, 'from his own writings.' (Eusebius, *Hist. Eccl.*, iii. 39; Cave, *Hist. Lit.*, under 'Papias;' Lardner's *Credibility*, pt. ii., c. 9.)

PAPIER-MÂCHÉ, the French term for a preparation of macerated paper, of which many articles are manufactured in England, France, and Germany. Such articles have been made in France for more than a century, for in 1740 one Martin, a German varnisher, went to Paris to learn the manufacture from Lefevre. On returning to his own country, he was so successful in his exertions, that his paper snuff-boxes were called, after him, 'Martins.' So much money went from Prussia to France in purchase of papier-mâché articles, that Frederic II., in 1765, established a manufactory at Berlin, which soon became very successful. Brunswick, Nürnberg, Vienna, and other German towns by degrees commenced the manufacture, and it is now carried on to a considerable extent.

Two modes are adopted of making articles of this kind: 1, by glueing or pasting different thicknesses of paper together; 2, by mixing the substance of the paper into a pulp and pressing it into moulds. The first mode is adopted principally for those articles, such as trays, &c., in which a tolerably plain and flat surface is to be produced. Common millboard, such as forms the covers of books, may convey some idea of this sort of manufacture. Sheets of strong paper are glued together, and then so powerfully pressed that the different strata of paper become as one. Slight curvatures may be given to such pasteboard when damp by the use of presses and moulds. Some of the snuff-boxes are made by glueing pieces of paper, cut to the sizes of the top, bottom, and sides, one on another, round a frame or mould, which is afterwards removed. Articles made of pasteboard have often a fine black polish imparted to them in the following manner:—After being done over with a mixture of size and lampblack, they receive a coating of a peculiar varnish. Turpentine is boiled down till it becomes black, and three times as much amber in fine powder is sprinkled into it, with the addition of a little spirit or oil of turpentine. When the amber is melted, some sarcocolla and some more spirit of turpentine are added, and the whole well stirred. After being strained, this varnish is mixed with ivory black, and applied in a hot room on the papier-mâché articles, which are then placed in a heated oven. Two or three coatings of the black varnish will produce a durable and glossy surface impervious to water.

Papier-mâché, properly so called, however, is that which is pressed into moulds in the state of a pulp. This pulp is generally made of cuttings of coarse paper boiled in water, and beaten in a mortar till they assume the consistence of a paste, which is boiled in a solution of gum-arabic or of size to give it tenacity. The moulds are carved in the usual way and the pulp poured into them, a counter-mould being employed to make the cast nothing more than a crust or shell, as in plaster-casts. In some manufactories, instead of using cuttings of made paper, the pulp employed by the paper-maker is, after some further treatment, poured into the moulds to produce papier-mâché ornaments.

The use of ornaments made in the way just described is greatly increasing. The carved and composition ornaments employed in decorating picture and glass frames are in some cases superseded by those of papier-mâché; but it is in the decoration of ceilings and walls of rooms and the interiors of public buildings that papier-mâché is found most valuable. Plaster and composition ornaments are very ponderous; carved ornaments are costly; but those of paper are light and of moderate price. In many of our theatres, in the House of Lords, in the Pantheon Bazaar, in some of the splendid steam-boats recently built, and in numerous other instances, where internal decorations are required, papier-mâché ornaments have been largely employed. Maps in relief are also occasionally made of papier-mâché.

The most remarkable instance of which we have heard of the employment of papier-mâché is one of which mention is made in a recent volume of Ersch and Gruber's 'Allgemeine Encyclopädie.' Near Bergen in Norway a church has been built capable of holding nearly a thousand persons. The building is octagonal without, but perfectly circular within. The interior of the walls as well as the exterior of the Corinthian columns, is covered with papier-mâché. The roof, the ceiling, the statues within the church, and the basso-rilievos on the outside of the walls, are also made of this substance. The papier-mâché was made waterproof and nearly fire-proof by an application of vitriol water and lime slaked with whey and white of egg. We may here remark, that paper roofs have been occasionally used in England. Sheets of stout paper are dipped in a mixture of tar and pitch, dried, nailed on in the manner of slates, and then tarred again; this roof is waterproof, but it is unfortunately very combustible.

PAPILIONA'CEÆ, a fanciful name given to the principal division of Leguminous plants, from an imaginary resemblance between their flowers and a Papilio, or butterfly. This appearance is owing to the excessive irregularity of the petals of such plants, one petal being large and expanded flat, and the other four arranged in a peculiar manner, and much smaller. The garden pea offers a familiar example of this structure. In technical language, the back or largest petal is the *vexillum*, or *standard*, the two external of the lateral petals *alæ*, or *wings*, and the two interior, which adhere by one edge, the *carina*, or *keel*.

PAPINIA'NUS, ÆMI'LIUS, was a pupil of the jurist Q. Cervidius Scævola at the same time with Septimius Severus, afterwards emperor. Under the emperor Marcus Aurelius he held the office of advocatus fisci, in which he succeeded S. Severus. After Severus became emperor, Papinian was his libellorum magister, and præfectus prætorio. Paulus informs us that he had given an opinion before Papinian in his auditorium. (*Dig.*, 20, tit. 5, s. 12; *Dig.*, 12, tit. 1, s. 40.)

Severus was always on intimate terms with Papinian, and at his death recommended to him his two sons Caracalla and Geta. Caracalla murdered his brother, and shortly after put to death Papinian, together with Papinian's son, who was quæstor. The cause of this execution is only obscurely stated (Spart., *Sever.*, c. 21; *Anton. Carac.*, c. 8); but it appears that the rigid morality of Papinian was shocked by the brutal conduct of Caracalla, and that he showed his disapprobation of his unnatural act.

Few Roman jurists were held in higher estimation than Papinian, and he is often cited in the most honourable manner both by the historians (Spart., *Sever.*, c. 21) and in various parts of the code (*Cod.*, 5, tit. 71, s. 14, &c.). Justinian (*Const. ad Antecess.*) in the course of study which he laid down after the completion of the 'Institutes,' 'Digest,' and 'Code,' in speaking of the third year's course of study, makes special mention of Papinian. The twentieth, twenty-first, and twenty-second books of the 'Digest' were enjoined to be read in place 'acutissimi Papiniani;' the name *Papinianistæ* was still to be retained by the students of the third year, and the festival formerly celebrated on the occasion of commencing his work, it was declared, should be solemnly kept as usual, in order that the memory of the great Papinian might be for ever preserved. The 'Digest' contains extracts from his thirty-seven books of 'Quæstiones,' his nineteen books of 'Responsa,' and fragments from his two books of 'Definitiones,' his two books on 'Adulteria,' and a single book on 'Adulteria;' also from a Greek fragment, entitled *ἐκ τοῦ ἀστυνομικοῦ μονοβίβλου Παπινιανοῦ*, that is, 'On the duty of the Ædiles in Rome and the Municipia.' Papinian is chiefly quoted by Paulus and Ulpian, and sometimes also by Marcian. The proportion which the extracts from Papinian bear to the whole 'Digest' is stated under JUSTINIAN'S LEGISLATION.

PAPI'RII, the name of a patrician and plebeian gens in antient Rome, who were formerly called Papisii.* (Cic., *Ad Fam.*, ix. 21.) This gens was divided into several families, such as the Mugillani, Crassi, Cursores, and Massones; and the most celebrated of the different individuals of these families was **Lucius Papirius Cursor**, who was the grandson of L. Papirius Cursor, who was censor in the year in which Rome was taken by the Gauls (Liv., ix. 34), and son of Spurius Papirius Cursor, who was military tribune in B.C. 379 (Liv., vi. 27).

---

* According to Pomponius, the letter r was invented by Appius Claudius; so that instead of Valesii and Fusii, the Romans afterwards said Valerii and Furii. (Dig. 1, tit. 2, s. 2, § 36.)

We first read of L. Papirius Cursor as master of the horse to L. Papirius Crassus, who was created dictator B.C. 339, by the consul Manlius, in order to carry on the war against the Antiates. (Liv., viii. 12; Cic., *Ad Fam.*, ix. 21.) The time of his first consulship is doubtful. Livy mentions C. Pœtilius and L. Papirius Mugillanus as consuls in B.C. 325; but he adds that instead of Papirius Mugillanus, the name of Papirius Cursor was found in some annals. (Liv., viii. 23.) During the year of their consulship the Lex Pœtilia Papiria was passed, which enacted that no one should be kept in fetters or bonds, except for a crime which deserved them, and only until he had suffered the punishment which the law provided; it also enacted that creditors should have a right to attach the goods, and not the persons, of their debtors. (Liv., viii. 28.)

In the following year Papirius Cursor, who is said by Livy (viii. 29) to have been considered at that time the most illustrious general of his age, was appointed dictator to carry on the war against the Samnites. He appointed Q. Fabius Maximus his master of the horse; and during his absence at Rome to renew the auspices, Fabius attacked the enemy contrary to his commands and gained a signal victory. On his return to the camp, he commanded Fabius to be put to death; but the soldiers espousing the cause of the latter, the execution was delayed till the following day, before which time Fabius had an opportunity of escaping to Rome, where he placed himself under the protection of the senate. The proceedings which followed are interesting to the student of the constitutional history of Rome, as they show that an appeal (*provocatio*) could be made to the people from the decision of a dictator, which is in accordance with a remark of Livy in another part of his history (iii. 55), that after the decemvirs were expelled from Rome, a law was passed, enacting that in future no magistrate should be made from whom there should be no appeal. Papirius demanded Fabius of the senate; and as neither the entreaties of the senators nor those of the father of Fabius, who had been dictator and three times consul, could induce Papirius to pardon him, the father of Fabius appealed (*provocavit*) to the people, and at length, at the earnest entreaties of the people and of the tribunes of the plebs, the life of Fabius was spared. Papirius named a new master of the horse, and, on his return to the army, defeated the Samnites, and put an end to the war for the time. (Liv., viii. 29-37.)

Papirius was elected consul a second time with Q. Publius Philo, in B.C. 320, and again defeated the Samnites; and apparently a third time in the following year, though there appears to be some doubt upon the latter point. (Liv., ix. 7-16.) He was consul for the fourth time in B.C. 315 (Liv., ix. 22), and for the fifth time in B.C. 313 (Liv., ix. 28). He was again named dictator in B.C. 309, to carry on the war against his old enemies the Samnites, whom he defeated with great slaughter, and obtained, on account of his victory, the honour of a triumph (Liv., ix. 38, 40); after which time we find no further mention of him.

Papirius Cursor, says Livy (ix. 16), was considered the most illustrious man of his age; and it was thought he would have been equal to contend with Alexander the Great, if the latter, after the conquest of Asia, had turned his arms against Europe.

PAPIST, an appellation derived from *papa*, 'the pope,' and which denotes a follower of the Roman church. That church calls itself catholic, which means 'universal;' but as other Christian churches also style themselves 'catholic,' a distinction seems required to avoid confusion. The appellation Roman Catholic is generally used all over Europe to denote a follower of the church of Rome, in contradistinction to the followers of other Christian communions; but in Great Britain the words Papist and Romanist have been long in common use; the former especially being employed in vulgar language, with a certain degree of prejudice and obloquy attached to it. The origin of the word 'papa' is given under Pope.

PAPPUS, ALEXANDRI'NUS, an eminent mathema- an of Alexandria, who flourished about the end of the h century of our æra. In the very brief accounts we have of him, he is mentioned as the author of sever treatises, all of which, except his 'Mathematical Collect (Μαθηματικαὶ Συναγωγαί), probably the most valuable of writings, appear to have perished. This work, as its imports, is miscellaneous; and besides a variety of pr sitions, both problems and theorems, contains some cur notices, not found elsewhere, of the history of mathemat and of mathematicians in his own and in preceding times. the eight books of the 'Mathematical Collections,' the f and about one half of the second are presumed to be l the rest have reached the present time, though with m imperfections, and in some passages so mutilated that meaning cannot be certainly determined. The orig Greek, except some short extracts, has never been print and the only translation of it, which is by Command was first published at Pesaro in 1588; and another edit with little variation or improvement, was printed in 1 at Bologna. This translation is accompanied with a mentary, often tedious, and in some places defective; at the same time it is extremely valuable, from the ex nation which it contains of some difficulties, and the rection of many errors in the manuscript used by Com dine, and which pervade all the manuscripts of Papp have hitherto been examined. From Commandine's ma of referring to the Greek, it appears that he had on manuscript for his guide. He died before the work received his last corrections, and no account is given of history or character of the manuscript which he fol From a family dispute between two sons-in-law, the p cation was suspended for some time after his death; length, by the munificence of his patron, the duke of Ur the translation was printed, but confessedly without a rection whatever of the errors or omissions in the unfin work of Commandine. In this state however it was a ve interesting communication to the mathematicians of age, and almost immediately excited the greatest inte and attention towards the Greek geometry.

The two first books of Pappus are not in Command translation, from their not being found in any of the M to which he had access; but a portion of the second was afterwards found in a MS. in the Savilian Librar Oxford, and published by Dr. Wallis in 1658, with a L translation, and valuable notes explanatory of the G arithmetic. From this remaining fragment, it is rea conjectured by Dr. Wallis that these two books solely to that arithmetic; and thence he infers that loss of them is not greatly to be lamented: the whole of the second book appears to be equivalent to what is considered as a very simple proposition, viz. that the mu plication of any numbers, all or any of which have cyph annexed, may be performed by multiplying these num without the cyphers, and then adding all the cyphers to product. The first book was probably employed about simple operations of the addition and subtraction of n bers. The third book contains geometrical problems linear and solid. The fourth contains theorems of pl solid, and linear classes of propositions. The fifth tr principally of isoperimetrical figures. The sixth is ployed chiefly in explaining and correcting some prop of Theodosius and some other antient writers, in trea on spherics. The seventh book is entirely on the an analysis. The eighth and last book is entirely on chanics; but though a curious document of the state of branch of science in the time of Pappus, yet, from great improvement both in the theory and prac mechanics in modern times, it is comparatively of value.

(Dr. Trail's *Life of Simson*; Suidas, in voc. 'V Chronologiâ Mathematicorum;' and *Montucla*, tom.

PAPPUS is a peculiar form assumed by the certain flowers chiefly of the natural order C Owing apparently to the want of sufficient space in which to grow larger, the calyx of such plants remains in a rudimentary condition, sometimes b mere rim, but more frequently expanded into scaly hairs, or similar processes, which are in most instances lourless. The *down* of the Dandelion is a familiar ins of pappus in a state of beautiful division resembl feathers.

PAPUA, commonly called New Guinea, is an isl great extent, situated at the junction of the Indian Pacific Oceans. It is separated by Torres Strait the northern extremity of Australia; by the St

Galewo from the small island of Salawatty, which lies farther west; and by Dampier's Strait from New Britain, which is to the east of it. It extends from 10° S. lat. nearly to the equator. The most southern point, Cape Rodney, is in 10° 5' S. lat., and the most northern point, Cape Good Hope, in 0° 19' S. lat. From west to east it extends between 130° and 151° 30' E. long.; the most western point, Cape Pula, on Galewo Strait, is in 130° 2' E. long., and the most western Cape Rodney, in 149° 30' E. long. Its length, from east-south-east to west-north-west, is nearly 1300 miles. Its width varies between 300 and 18 miles. The main body of the island, east of 135° E. long., constitutes a vast extent of continuous land, with a projecting peninsula at its eastern extremity, but between 133° and 135° E. long. a wide and open bay enters deeply into the land. This bay, called Geelvink, or Great Bay, is nearly 200 miles wide at its entrance, in which some islands of considerable extent are situated, and penetrates about 200 miles southward into the body of the island. The southern extremity of this bay is separated from the Molucca Sea by an isthmus only about 19 miles wide. That part of the island which is west of this isthmus greatly resembles in form the islands of Celebes and Gilolo, consisting of a projecting peninsula and deep inlets. The largest of the inlets is MacCluer's Bay, which is upward of 100 miles long. According to a rough estimate, the surface of the island is 270,000 square miles, or about 55,000 square miles more than the area of France.

The surface and soil of this island are only known so far as they have been seen by navigators who have sailed along the coast. There are few places on which Europeans have landed, and in no place have they penetrated more than a few miles inland. The south-eastern peninsula, which terminates with Cape Rodney, is formed by a continuous chain of high hills; and, as far as we know, a high and mountainous country extends along the northern shores of the island; the ascent of the mountains however is in general gradual, and though in several places they attain a considerable elevation, as Mount Arfak, south of Dory Harbour, none of them appear to rise to the snow-line. The declivities of the mountains are generally covered with wood, but these forests are free from underwood, which is rather a rare occurrence between the tropics. Small rivers are numerous, and there are probably some larger streams in the wider part of the island. In some places the surface is covered with good grass. Along the northern coast the sea is deep enough to be navigated by the largest vessels, and there are a few good harbours. At a distance of from 10 to 20 miles from this coast there are numerous islands, which seem to lie in a row, and among which several are of volcanic origin. Dampier noticed three active volcanoes.

Along the southern shores, the country west of the isthmus is likewise mountainous, and the coast rather high and rocky, but it does not rise to any considerable elevation on the shores of MacCluer's Bay. The isthmus itself is formed by a chain of high hills. East of the isthmus, as far as Cape Buro (135° E. long. and 4° S. lat.), the mountains advance close to the shore, and the sea can be navigated by large vessels. Cape Buro rises to a great height close to the sea; but east of this promontory the mountains recede farther inland. They are visible from the sea as far east as 138° E. long., but appear to be a great distance from the shore, which shows that they must attain a considerable elevation. Some navigators think that they have observed snow on them. No mountains appear east of 138°. The country between the sea and the mountains, and the whole country east of 138°, as far as it has been seen, is very low, and covered with extensive swamps, but generally occupied by lofty trees. This low coast cannot be approached, as it is lined by a broad belt of mud-banks. At a distance of from six to ten miles the depth of the sea does not exceed four or five fathoms, and it gradually decreases towards the land. Boats which try to effect a landing stick fast in the mud at the distance of one or two miles from the beach. South of 8° S. lat. a wide and low promontory projects into the sea, between 138° 20' and 139° E. long. It is called Valsche Caap (Cape False), and up to 1835 was considered a part of Papua, but in that year a Dutch vessel discovered a strait between it and the mainland of Papua. This strait is called *Princess Marianne Strait*, and the island, which is divided by it from Papua, has received the name of *Frederik Hendrik's Island*. This island is low and swampy, but covered with trees. Along the low shores are the mouths of some considerable rivers. Four of them occur between 136° and 137°, and are named, from west to east, Wamoka, Dianara, Valsche Wakka, and Valsche Dianara. These rivers are not accessible to vessels, on account of the extensive mud-banks at their mouths.

We are not acquainted with the climate of this country, except so far as it may be inferred from its geographical position and the nature of the surface.

The natural productions of these islands are little known. The only animals are dogs, wild cats, and hogs, which are rather plentiful. Fish and turtle abound, and the inhabitants of the coast subsist chiefly on them. Agriculture is limited to the planting of two kinds of bread-fruit trees and cocoa-nut palms. But the inhabitants of the interior, the Haraforas, are said to practise gardening and some sort of agriculture. It does not appear that the sago-palm grows on this island, as the Papuas fetch it from the island of Waygiou. Nor are the cocoa-nut palms numerous. Lemons, limes, bamboo, and rattans seem to grow spontaneously. It is supposed that gold is found in the interior.

Inhabitants.—Papua is inhabited by two or perhaps three nations. Along the coast of the western half of the island are the Papuas, who have received that name from the Malays, in which language the word signifies 'frizzled hair.' They are considered to belong to the same race as the inhabitants of Australia, but there appears to be some difference between them in the structure of their body, though they agree in their woolly hair, and also nearly in colour. The Papuas are rather stout, and not so slender and short as the Australians. Their eyes are small and dark; the nose somewhat curved and projecting downwards; the lips thick, the mouth large, and the teeth exceedingly white. Though stouter than the Australians, they are not so stout as the African negroes. Though placed near the line, they do not go entirely naked. The men wear a thin stuff, made of the fibres of the cocoa-nut tree tied round their middle and between their legs; the women are dressed in the same manner, but they wear blue Surat cloth. Their residences exhibit a greater degree of civilization. Forrest found in the harbour of Dory, on the northern coast, two large houses built on posts fixed several yards below low-water mark; and a long stage, likewise fixed on posts, went from it to the land just above high-water mark, while another of the same kind stretched out seaward. This tenement contained many families, who lived in cabins on each side of a wide common hall that went through the middle of it, and had two doors, each opening to one of the stages. The married people, unmarried women, and children lived in this tenement and the adjacent cabins, but the bachelors inhabited a separate house, at some distance from the stage, lying seaward, in deeper water, and resting on stronger posts. Besides fishing, they carry on some trade with the Chinese, who visit the northern coasts, and exchange some of the goods obtained in this way for provisions with the Haraforas. The Papuas seem to constitute a great number of small political societies, and to speak a variety of dialects, or perhaps languages.

The Haraforas inhabit the interior of the western half of the island, but in the eastern district they seem to be in possession of the shores, especially along the southern coast, where the country is low. They live in huts, built between the branches of high trees, to which access can only be had by a ladder, which is drawn up during the night. They are said to be distinguished from the Papuas by a lighter colour, straight hair, and greater strength and activity of body. They are cannibals, and no person is permitted to marry until he can show the skull of a man whom he has killed. In this they resemble some tribes of Borneo and the Battas of Sumatra. They seem to have made some progress in agriculture, and they raise provisions, among which are plantains and kalavansas, which they sell to the Papuas. It is, according to our ideas, difficult to comprehend in what relation they are placed to the Papuas. Forrest states that a Harafora, by receiving an axe or chopping-knife from a Papua, makes his land or his labour subject to a perpetual tax of something, according to agreement. If the Harafora loses the instrument, he is still subject to the tax; but if he breaks it or wears it to the back, the Papua is obliged to give him a new one, or the tax ceases.

Commerce.—No European nation has at present any commercial intercourse with Papua, nor, as far as we know has this island been visited by European vessels for that purpose. The Chinese and the inhabitants of the Ceram Lant and Goram Islands appear to carry on a very lucrative trade, the former on the northern and the latter on the southern coast. The Dutch, who have several settlements on the Molucca Islands, and consider Papua as one of their possessions, do not permit their countrymen to trade to Papua, for fear of the introduction of fire-arms and ammunition, in spite of the regulations made to prevent it; but they give permission to the Chinese to trade on the northern coast. The Chinese import into Papua iron tools, especially chopping-knives and axes, blue and red cloths, China-beads, plates, basins of China and other similar articles, and take in return, slaves, ambergris, trepang, tortoise-shell, small pearls, black loories, large red loories, birds of Paradise, and many kinds of birds which the Papuas have a peculiar way of drying. But the principal article of export is a bark called masoy bark, which is taken to Japan, where the powder made of it is extensively used for rubbing the body. In Japan a pecul of this bark fetches thirty dollars. The harbour of Dory, near the western side of the Bay of Geelvink, is the most frequented by the Chinese.

The Ceram Lant and the Goram Islands are two small groups lying south-east of the eastern extremity of Ceram. The inhabitants of these islands are very active and good seamen. They traverse the Molucca and Java seas, and go as far as Sumbawa and Bali; but their most lucrative commerce is with Papua. It is supposed that the decided animosity with which the Papuas commonly receive Europeans is chiefly to be ascribed to the notions instilled into them by these traders, who also use every artifice to impress on their mind a similar hatred against the Bugis from Celebes and against the Chinese, fearing these two nations as rivals in their commercial transactions. This commerce seems to be very extensive, as it is stated that one village or town on the island of Goram, called Enekka, sends twenty-five junks to Papua. They principally visit the Bay of Lokayic, Onie, and Karrats-Quey: the locality of the two last-mentioned places is unknown. The exports consist of masoy-bark, nutmegs, pearls, trepang, edible bird-nests, birds of Paradise, and several other valuable articles. Kolff, who gives this list, does not mention the articles of import, of which however cotton-cloth and iron seem to be the most important; but he adds that one can hardly imagine what quantities of these articles are annually exported by these islanders, and afterwards sent to Bali or Singapore, or sold to the Chinese settled on the Moluccas. It seems that his report of this extensive traffic has been the principal inducement to the Dutch government for founding a colony on this coast.

History.—The Portuguese discovered the western part of Papua soon after they had settled in the Moluccas, between 1512 and 1530. The Spaniard Saavedra visited it in 1528. Several other navigators discovered other parts of the coast. Our countryman Dampier discovered the strait which divides the island from New Britain, and sailed along the whole extent of its northern coast. In 1792 MacCluer surveyed the bay which bears his name; and in 1802 Flinders examined the country adjacent to Torres Strait, which was discovered by the Spaniard Torres in 1606. In modern times Kolff, a Dutchman, has discovered and surveyed the south-western coast; and, as already observed, on his report respecting the advantageous trade which may be carried on with this island, the Dutch government founded a colony, and erected, in 1828, a small fortress on a spacious bay, called by the natives Ooroo-Langooroo, and by the Dutch, Tritons Bay. The fortress, which is called Dubus, is situated in 3° 42′ S. lat. and 134° 15′ E. long.

(Forrest's *Voyage to New Guinea and the Moluccas*; Leyden, in *Asiatic Researches*, vol. x.; Delano's *Voyages and Travels*; Kolff's *Reize door den Weinig Bekenden Zuidelijken Molukschen Archipel en langs de Geheel Onbekende Zuidwest Kust van Nieuw Guinea;* and Modera's *Verbadl van eene Reize nar en langs de Zuidelijken West Kust van Nieuw Guinea gedaun in* 1828.)

PAPY'RUS, in botany, is a Cyperaceous aquatic plant, whose soft cellular flower-stem afforded the most antient material from which paper was prepared. It has a stem from three to six feet high, with three acute angles, one of which, according to Bruce, is always opposed to the current of the stream in which it grows, as if to break its force. Its leaves are long and grassy, with a sharp keel. The flowers, which are green, are produced in very large compound umbels, with extremely numerous drooping triangular slender radii, terminated by very long filiform involucral leaves, within which are placed the spikes of flowers, each consisting of from six to thirteen florets. It is usually regarded as a species of *Cyperus*, and is called *C. Papyrus*; by most botanists it is considered a distinct genus, and is named *Papyrus antiquorum*. It is a very common plant in Abyssinia, Egypt, and Syria, and is also met with in Calabria and Sicily; in gardens it is not uncommon. It inhabits both stagnant waters and running streams, and, independently of its antient employment in the fabrication of paper, has been applied to other uses. The flowering stems and leaves were twisted into ropes; the roots are sweet, and have been employed as food. In Abyssinia boats are constructed from it, according to Bruce. In Syria the plant is called *Babeer*.

PAPY'RUS is not only the name of the plant, but also of the material which used to be derived from it for writing upon; and the written scrolls made of that material which have been found in various countries are called papyri. The antients employed for this purpose the thin concentric coats or pellicles that surround the triangular stock of the plant, those nearest the centre being the best and finest; they cut them into strips of a certain length, and placed them side by side in a layer on a board, another layer of the same material being pasted over it crosswise, so as to form a sheet of convenient thickness, which, after being pressed and dried in the sun, was polished with a shell or other hard and smooth substance. A number of these sheets, about twenty in general, were glued together to form a scapus, or roll. The breadth of the roll was determined by the length of the slips taken from the plant, the broadest being about thirteen fingers' breadth, and others ten; the length of the scapus or roll might be carried to almost any extent: some have been found as long as thirty feet. The writing, as in all antient rolls of whatever material, is in columns, extended in the direction of the length of the roll, with a blank strip between them. In the Egyptian papyri, the lines run in the direction of the length of the papyrus for six or eight inches, and when the scribe came to the bottom of the papyrus, he began a new page to the left of the first, leaving between the first and second page a small blank strip, which of course would lie in the direction of the breadth of the papyrus. In some cases the pages are divided by perpendicular lines evidently drawn with a rule. We know from Herodotus that the Egyptians wrote from right to left like the Hebrews and Arabs, and this fact is readily proved by the inspection of a papyrus. The commencement sometimes contains a drawing or certain characters larger than the rest, corresponding to capital letters in our writing; these characters always stand at the right extremity of the line. The form of the strokes of many of the characters shows clearly that in making them the hand passed from right to left. The last line of a page, when it is not a complete line, terminates in such a way as to show that it commenced at the right side. Where a phrase or period is not completed at the bottom of the page, the continuation of it is found at the top of the next page or column to the left; and it is certain that in such cases this is the continuation of the incomplete phrase or period, because the two parts (that at the bottom of one page, and that at the top of the next) occur in other parts of the papyus in one continuous series. The same characters are often recognised at the commencement of the different pages, and these initials are very often written in red ink. Sometimes the first lines of the pages are exactly the same. ('The British Museum: Egyptian Antiquities,' vol, ii., ch. 7, in the *Library of Entertaining Knowledge.*) A framed papyrus (No. 16) in the Egyptian room of the British Museum is a good specimen of the style of writing.

Besides the papyri written in the enchorial or common language, there are others marked with hieroglyphic or pictorial characters, and these are generally divided by red lines into narrow columns of one inch or less in breadth, in which the symbols are placed one under another, and the columns are arranged from right to left, as in the enchorial writing.

Many papyri written in Greek have also been found in Egypt, some of which are interesting as being the oldest written records of any language that is understood in our times. The Greek papyrus of Mr. Grey, now in the British Museum, is probably of B.C. 135, and contains the translation of a deed of sale, the text of which, in enchorial characters, is on a papyrus at Paris; and another copy, likewise in enchorial characters, was brought to Berlin from Egypt, by General von Minutoli. The identity of the three is proved by their having the same registry on them in Greek. An English translation of the Greek papyrus is given in the above-quoted chapter of the 'Egyptian Antiquities,' with the text in the appendix, and likewise a translation of a Greek papyrus from Thebes, containing another deed of sale, dated in the reign of Cleopatra and Ptolemy her son, about 106 B.C.

The Egyptian museum at Leyden contains one hundred and forty-seven papyri, some in Greek, others in enchorial, some in hieroglyphic characters, and some bilingual.

There is among the Vatican papyri a specimen written in the enchorial or common characters, on which Champollion reads a date, expressing the twelfth year of Psammetichus, B.C. 640. Several papyrus rolls of the age of Darius, the son of Hystaspes, are said to be in the collections of Paris and Turin.

We have the testimony of Herodotus (v. 58), that Egyptian papyrus was an article of commerce, and a material for writing long before his time. He calls it byblos, from the Egyptian name of the papyrus plant, from which perhaps the Greek name 'biblion,' for book, has been derived. There was a town in the Delta called Byblus. 'The byblos,' says Herodotus, 'annually springs up; after it is plucked from the marshes, the top is cut off and converted to a different use from the other parts. The bottom part that is left, to the length of about one foot and a half, they sell as an eatable commodity.' And in other passages he notices incidentally the uses to which the top part was turned. 'The priests wear shoes made of the byblos; the sails of the Egyptian boats are made of byblos; the priests read to me out of a byblos roll the names of three hundred and thirty kings.' With the possession of Egypt by the Greeks the use of papyrus increased, and was for many centuries an important branch of export from that country; and although linen, parchment, and other kinds of writing materials were used, we may infer from passages in antient authors that none was in so great demand as papyrus. The vast quantity of papyri found at Herculaneum proves the extensive use of it in Italy. At the commencement of the sixth century Cassiodorus (xi., Ep. 38), in one of his letters, congratulated the world on the abolition by king Theodoric of the high duty on imported papyrus; and speaks in animated terms of the usefulness and general use of that material. Papyrus continued to be used in Italy till about the eleventh or twelfth century, when it was superseded by cotton paper introduced from Asia. There is a papyrus at Ravenna, of the twelfth century, containing a brief of pope Paschal II. in favour of that archiepiscopal see.

The Egyptian papyri found in rolls under the swathings of mummies are often in a good state of preservation, but require great care in handling and unrolling them, being very dry and brittle to the touch. M. Jomard (*Description de l'Égypte*, vol. iii., p. 119) gives useful directions concerning the method for unrolling them. Papyrus rolls are also found in earthen vessels. The colour of the papyrus is a brownish yellow, and the characters and the drawings are in general perfectly legible; in some specimens the writing is of a good close black. A papyrus-book made of sheets of papyrus sewed together was brought from Egypt by Dr. Hogg, and is now in the British Museum. The MS. is a copy, in Greek, of part of the Psalms of David.

The papyri found at Herculaneum are burnt almost to cinders; and after all the trouble which has been taken, and the ingenuity that has been displayed in unrolling and deciphering many of them, little or nothing has been found worthy of the pains. They consist chiefly of Greek sophists and rhetoricians, works on music, medicine, and the arts, and some on natural and moral philosophy, &c. None of the lost historical works or fragments have been discovered among them. The work, 'Herculanensium Voluminum quae supersunt,' published at Naples, the last volume of which appeared in 1827, contains the text of the deciphered papyri. Many other Greek and Latin papyri of various ages are scattered about the various libraries and museums of Europe.

The papyrus reed has become scarce in Egypt; but it is recorded as still existing about the lake Menzaleh, near Damiat. There is a Sicilian water-plant resembling the papyrus, which is found in the Anapus near Syracuse, from which some samples of paper have been manufactured in recent times, according to the antient method for preparing papyrus, which is described by Pliny (xiii. 11, 12).

The name for paper in the Spanish, French, German, and English languages is derived from that of papyrus, whilst the Italian has retained the Latin word 'charta,' which was used for parchment and other materials for writing.

PAR OF EXCHANGE. [EXCHANGE.]

PAR VAGUM. [BRAIN.]

PARA', or, with its full title, *Santa Maria de Belem do Gram Pará*, is a town in Brazil, in 1° 18' S. lat. and 48° 22' W. long. It is built on the eastern banks of a wide river, which is formed by the confluence of the river Tocantins with the Tagipurú, or southern arm of the Amazonas, and is called Rio do Pará. Opposite the town the river is about seven miles wide, and this may be considered as its mean width to its mouth, a distance of more than seventy miles. This extensive sheet of water contains numerous low and woody islands, many of which are connected with one another by banks of mud, with only a few feet of water on them. The navigable channel is winding and generally of no considerable width. The approach of vessels to the town is accordingly rather difficult and tedious. On the south side of the town is the Rio Guamá, a considerable stream, which joins the Rio do Pará by a westerly course. The streets of Pará are wide and straight, and intersect one another at right angles. The houses are chiefly built of stone, but not high, consisting rarely of more than two floors and frequently of only one. They are only whitewashed, and frequently without glass windows. The cathedral is large and has a fine appearance. The best edifice in the town is the College of the Jesuits, now the residence of the bishop of Pará: a part of the building is occupied by the college, in which young persons study divinity. The church contiguous to the college has been converted into an hospital. The palace of the governor and the custom-house are also good buildings.

In 1820 the population was estimated at 24,500, and it has probably increased since that time. It consists of a considerable number of creoles and a larger number of aborigines, the number of negroes being much less in proportion than in other seaports of Brazil. The Indians are occupied as menial servants, fishermen, boatmen, and porters, but they do not exercise trades.

The commerce of Pará is considerable and increasing. The exports consist of sugar, rum, molasses, coffee, cacao, cotton, vanilla, copaiba, pitch, copal, fustic, timber, wood for cabinet-work, tobacco, ropes made from the fibres of palm-trees, sarsaparilla, rice, mandioc, starch, Indian-rubber, pechurim-beans, tonquin-beans, tamarinds, Cassia caryophyllata, indigo, arnotto, and Brazil nuts. To these must be added hides, horns, and horses: the horses are exported to the English islands in the West Indies, especially to Barbadoes. The latter articles are supplied by the island of Marajo, which lies opposite the town on the western side of the Rio do Pará. Only the sugar, rum, molasses, tobacco, cotton, and Indian-rubber are obtained in the vicinity of the town; the other articles are brought from the countries on both sides of the Amazonas, and frequently from a distance of a thousand miles and more. Pará sends several articles of European manufacture by way of the Amazonas and Rio Tapajos to the western interior province of Matto Grosso, from which it receives gold in exchange. Towards the end of the last century an attempt was made to transplant to the vicinity of this town cinnamon-trees, clove-trees, and nutmeg-trees, and though the plantations were afterwards neglected, they still exist, and supply small quantities of these articles for exportation.

The town was founded in 1615 by Francisco Caldeyra. At first its growth was slow, but since the middle of the last century, when Pombal formed a just notion of the importance of the country near the mouth of the Amazonas, he favoured this town, and it prospered accordingly. From that time to 1835 the town increased rather rapidly. In 1835 its prosperity was checked by an insurrection of the Indians of the province, who took possession of the town and kept it for about six months: but at present it has nearly recovered from the effects of that disastrous event.

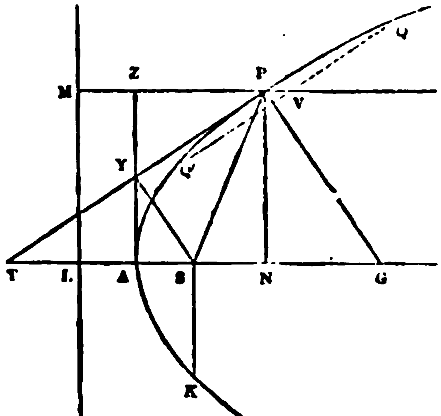
(Spix and Martius, *Reise in Brasilien*; Smyth and Lowe's *Journey from Lima to Pará*.)

PARABLE (παραβολή, 'a comparison or similitude') is defined by Bishop Lowth as 'a continued narrative of a fictitious event, applied by way of simile to the illustration of some important truth.' (*Praelect.* x.) It is a species of fable, and differs from the apologue by narrating events which, though fictitious, are not impossible to have happened. [Fable.] This mode of instruction is of great antiquity, especially among the eastern nations. In the Old Testament we have examples of it in the parable of Nathan to David (2 *Sam.*, xii. 1-9), in that of the woman of Tekoah (2 *Sam.*, xiv. 1-13), and repeatedly in the writings of the prophets (*Is.*, v. 1-7; *Ezek.*, xv., xvi., xix., xxxiii., &c.). The parable of Jotham, which is often spoken of as the most antient parable in existence (*Judges*, ix. 7-15), is properly an apologue. In the New Testament parables form a most marked feature of our Saviour's teaching. (See the gospels of Matthew, Mark, and Luke.) Lowth lays down as the essential qualities of a parable, that the image must be well known and applicable to the subject, and its meaning clear and definite; it must be elegant and beautiful in itself; all its parts and appendages must be perspicuous and pertinent; and the literal must never be confounded with the metaphorical sense.

Many of the Scripture parables are accompanied by an explanation, which, of course, fixes the sense. Where this is not the case, the intended meaning must be gathered from a consideration of the subject-matter of the parable itself, the context in which it occurs, and the circumstances under which it was uttered.

Besides its usual signification, this word is employed in the Scriptures in the following senses:—a proverb, a famous saying, a thing darkly or figuratively expressed, and a visible type or emblem.

PARA'BOLA. The probable origin of this name, as applied to one of the conic sections, may be seen in Rectangle. As in the case of the other Conic Sections [Ellipse and Hyperbola], we shall here give a small collection of the most remarkable properties of this curve.



1. Let a point P move in such a way that its distance SP from a fixed point S is always the same as its perpendicular distance PM from a given line ML. This point P describes what is called a parabola.

2. The line LS, perpendicular to LM, produced, is the *axis*, or principal diameter; and any line PV parallel to it is called a *diameter*. The point S is the *focus*, and the line LM the *directrix*. The ordinate SK drawn through the focus is called the *semi-latus-rectum*, and double of it is the *latus rectum*. The same phrase is used for the ordinate drawn through the focus of an ellipse or hyperbola.

3. SA is equal to AL, and SK to twice AS.

4. If an ellipse be described with the vertex A and the focus S, the farther the centre is from the point S, the more nearly will the part of the ellipse which falls within a given ordinate PN coincide with the corresponding part of the parabola: and the same of an hyperbola drawn with the vertex A and focus S. And a parabola may be considered as an ellipse or hyperbola with a given focal distance AS, and a centre at an infinite distance.

5. The tangent PT bisects the angle MPS, and SP is equal to ST, and AN to AT. The line SY drawn perpendicular to the tangent from the focus always meets PT in a point of the tangent drawn through A.

6. If PG be drawn perpendicular to PT, then SP is equal to SG, and NG is always equal to twice AS.

7. The square on PN is equal to four times the rectangle under AN and AS.

8. The area ANP is two-thirds of NZ, the rectangle under AN and NP.

9. If QQ′ be drawn parallel to PT through any point V of the diameter PV, QQ′ is bisected in V, and the square of QV is equal to four times the rectangle under SP and PV.

10. The square on SY is equal to the rectangle under AS and SP.

In applied mathematics the parabola was formerly of great importance, both as being the curve in which a comet was supposed to move, and as that in which a cannon-ball or other projectile would move were it not for the resistance of the air. It is still sometimes used as the approximation to the elongated ellipse in which a comet moves. For the more accurate investigations which deduce the real path of a projectile, see Gunnery.

PARABOLOID. The simplest form of this surface is the paraboloid of revolution, made by the revolution of a parabola about its axis. For the other meanings of the term, see Surfaces of the Second Degree.

PARACE'LSUS, the name commonly given to a very extraordinary person, who called himself by the compound and high-sounding appellation Philippus Aureolus Theophrastus Paracelsus Bombast, ab Hohenheim: to which is sometimes added the epithet *Eremita*. Of all these names it is difficult to say which, if any, really belonged to him; for though he seems to have liked *Theophrastus* better than any of the others, and sometimes (as in his will and his letter to Erasmus) called himself by that alone, and though he says, in his book called *Paragranum*, 'Et Naturæ et Baptismatis jure Theophrastus nominor,' still he was wont to pay so little regard to truth, either in his words or actions, that he cannot safely be believed even in such a trifle as this. The place of his birth is equally uncertain, but he is generally supposed to have been born in 1493, at Einsiedeln in the canton of Schwyz, the Latin name of which, 'Helvetiæ Eremus,' caused him to be sometimes called 'Eremita.' (See however Haller, *Biblioth. Med. Pract.*, tom. ii.) His father was a physician, and instructed him in alchemy, astrology, and medicine: he was never regularly educated, and he confesses himself that he was not fond of books and had a horror of languages, insomuch that at one time he did not open a book for ten years together. This is quite confirmed by the internal testimony of his writings, which are as unintelligible from their style as their substance. He soon commenced a wandering life, and spent some years in travelling over almost all Europe and probably several parts of Asia and Africa. He had a most ardent desire for information of all sorts, and neglected no opportunity of acquiring it; but he seems to have exercised very little judgment in the choice of his informants, and to have consulted conjurors, old women, and quacks of every description, quite as much as physicians and philosophers. The most valuable acquisition that he made in his travels was an acquaintance with metallic chemistry, by means of which he was enabled to perform several wonderful cures, and thereby laid the foundation of his fame. In 1526 he was chosen to be professor of medicine and natural philosophy at Basel, and commenced his course of lectures by lighting some sulphur in a brazen chafing-dish, and then throwing into the flame the works of Galen and Avicenna, exclaiming, 'Sic vos ardebitis in gehennâ.' He lectured partly in Latin and partly in German, which, together with his singular manners and the novelty of his opinions, rendered him extremely popular. In consequence however of a dispute with the magistrates about the amount of a fee which he demanded of one of the canons, he left Basel in about a year, and recommenced his wandering life. He seldom stayed long in one place, but lived chiefly in taverns, where he scarcely ever took off his clothes by day or night; and though he had hitherto lived a very temperate life, and taken nothing but water, he now spent whole nights in drinking with the lowest company. He still maintained his reputation by occasionally effecting some extraordinary cures by means of his powerful medicines, but his failures were equally conspicuous. At last, after passing through many vicissitudes, the boasted possessor of the philosopher's stone and the elixir of life died in great poverty in 1541, at Salzburg, in the Tyrol, at the early age of forty-eight.

As might be expected, Paracelsus has been as much extolled by his admirers as he was despised and abused by his accounts. With respect to his moral and religious character there seems to have been nothing to admire: he was totally destitute of piety, and his theological opinions (if they deserve to be called such) were a confused mixture of infidelity, heresy, and absurdity: in gluttony and drunkenness, in lying and charlatanism, in vanity and arrogance, he has been seldom equalled and never surpassed. If any one is inclined to think this judgment of him too harsh and severe, he will find it abundantly confirmed by the passages quoted from his own writings and those of his personal acquaintances by Le Clerc, in the Appendix to his 'Hist. de la Méd.' His intellectual talents and acquirements are not much more deserving of respect; but in order to estimate these fully, he must be considered—1, as a chemist; 2, as a physician; and 3, as a philosopher. 1. As a chemist (though probably the ablest of his time), he falls far short of his predecessor Basil Valentine. 'His original discoveries,' says Brande, in his 'Manual of Chemistry,' 'are few and unimportant, and his great merit lies in the boldness and novelty which he displayed in introducing chemical preparations into the *Materia Medica*, and in attacking the prejudices of the Galenical physicians against the productions of the laboratory. But though we can fix upon no particular discovery on which to found his merits as a chemist, and though his writings are deficient in the acumen and knowledge displayed by several of his contemporaries and immediate successors, it is undeniable that he gave a most important turn to pharmaceutical chemistry, and calomel, with a variety of mercurial and antimonial preparations, as likewise opium, came into general use.' He pretended [illegible] to possess the secret of the philosopher's stone and the elixir of life, besides various other preparations called by strange and uncouth names, such as 'the Quintessence,' 'the Arcanum of Vitriol,' 'Azoth,' &c.: the composition of his 'Laudanum' he is supposed never to have revealed, and in the short dictionary at the end of his works we are merely told that 'Laudanum Theophr. Paracelsi est medicina laude dignissima ex duabus tantum rebus constans, quibus excellentiores in mundo reperiri nequeunt: quæ morbos omnes fere sanat.' 2. As a physician he cannot lay claim to any scientific skill; and though his epitaph declares that 'Lepram, Podagram, Hydropisam, aliaque insanabilia corporis contagia mirificâ arte sustulit,' we are told on the other hand that 'he killed many of his patients, or at least made them worse than they were before.' (Libavius, *Hist. Panac.* [illegible], quoted by Le Clerc.) His medical writings are full either of credulity or imposture. He says that it is possible for a man alone to create a living child resembling in every respect those born of women, only much smaller, and he gives directions for doing so, too absurd and indecent to be quoted. He explains minutely the analogy which he supposes to exist between the *Macrocosmus*, or external world, and the *Microcosmus*, or human body, and says that every physician ought to be able to point out in man the east and west, the signs of the zodiac, &c. (*Paragranum*, Tract. 2.) He says that the human body consists of nothing but sulphur, mercury, and salt. (*Paramirum*, lib. 1.) He professes his belief in magic (though in this he was not more credulous than his contemporaries), and boasts of having received letters from Galen, and of having disputed with Avicenna in the vestibule of the infernal regions. (*Paragranum*, Præf.) Some of his most remarkable cures were cases of syphilitic and other obstinate ulcers, and his 'Chirurgia Magna' and 'Chirurgia Minor' have been more esteemed than perhaps any of his other works. In extracting an arrow or other weapon from a wound, he recommends (when all other means fail) the use of certain *verba constellata*, which will infallibly succeed. 3. With respect to his philosophical (or theosophical) opinions, it is very difficult to discover what they were, not only from the great obscurity of the subject-matter of his works, but also from the new words that he employs, and still more from the peculiar and arbitrary sense that he puts upon those in common use. Iliaster, [illegible], Aniadum, [illegible], Cagastrum, Evestra, Trarames, [illegible], &c., are some of those invented by himself, and of which no intelligible explanation is to be found. 'He made great use,' says Tennemann (*Manual of Philos.*) 'of the cabalistic writers, whom he endeavoured to render yet [illegible] and expounded with a lively imagination. Among the principal mystic notions were those of an internal illumination as an emanation from the Divinity, the universal harmony of all things, the influence of the stars on the sublunary world, and the vitality of the elements, which he regarded as spirits encased in the visible bodies presented to our senses.' 'These are,' says Hallam (*Liter. of Europe*) 'the sylvans, sylphs, undines, or nymphs, gnomes, and salamanders. It is thus observable that he first gave these names, which rendered afterwards the Rosicrucian fables so celebrated. These live with man, and sometimes (except the salamanders) bear children to him; they know future events and reveal them to us; they are also guardians of hidden treasures, which may be obtained by their means.' The writer may apologize in Hallam's words, and confess that 'he may perhaps have said too much about paradoxes so absurd and mendacious; but literature is a garden of weeds as well as of flowers, and Paracelsus forms a link in the history of opinion which should not be overlooked.' His works, part of which are written in German and part in Latin, and of which a complete list is given by Haller, in his 'Biblioth. Medic. Pract.,' were published in Latin at Frankfort, 1603, in 10 vols. 4to., and in German, by Huser, at Basel, 1589-90, also in 10 vols. 4to. For more particulars respecting Paracelsus and his opinions, see Le Clerc, *Hist. de la Méd.*; Sprengel, *Hist. de la Méd.*; Brucker, *Hist. Crit. Philosoph.*; Rixner und Siber, *Leben und Lehrmeinungen berühmter Physiker*, &c., heft 1, Sulzb., 8vo., 1819.

PARACENTRIC, or 'towards the centre,' a term sometimes used, as in paracentric velocity, which means the rate at which a moving body approaches a certain centre without reference to the rate at which it moves in space.

PARACEPHALO'PHORA, M. de Blainville's name for his second class of *Malacozoaria*, which is divided by him into the subclasses *Paracephalophora dioica*, *Paracephalophora monoica*, and *Paracephalophora hermaphrodita*. [MALACOLOGY.]

PARACHUTE, a French word, signifying a means of preventing a fall. The first part of the word, *para*, is perhaps of Greek origin; the second part is the French word *chute*, a fall, which is of Latin origin.

A parachute is a machine attached to a balloon, and is intended to convey the aëronaut gently to the earth, in case of an accident happening to the balloon. It is in shape like an umbrella, and its construction may be understood by supposing the umbrella to be large and strong; to be provided with ropes or stays fastened to the extremities of the whalebones, and brought down to the handle, where they must be fixed, so as to prevent the umbrella from turning inside outwards. Instead of the stick, suppose a metal tube to be fixed in the centre, with a rope passing through it, attached by its upper extremity to the balloon, and by its lower end to a tub or car. This machine is a parachute: while ascending, it will be like a closed umbrella, but it may at any moment be detached from the balloon by cutting the end of the rope which is tied to the car; the resistance of the air will then cause it to expand, and will at the same time retard the velocity of descent.

The idea of using such a machine to break the fall from a high place is not new. Nearly two centuries ago De la Loubère relates that a man was in the habit of amusing the court of Siam by descending from a considerable height with such a contrivance. He used two umbrellas, fastened by long slender handles to a girdle tied round his waist; 'le vent le portoit au hazard, tantost à terre, tantost sur des arbres, ou sur les maisons, et tantost dans la rivière' (vol. i., p. 146, Amsterdam, 1691). The experiment was repeated in France in 1783, by M. le Normand, who leaped safely from the window of a house with a stout umbrella in his hand of thirty inches in diameter. The descent from a balloon was first tried on a dog by Blanchard, at Strasburg, in August, 1787. The animal was detached at a height considerably greater than a mile, and he reached the ground in safety. Blanchard was less fortunate in a subsequent experiment on his own person at Basle, where he broke his leg by too rapid a descent. Garnerin was the next adventurer; he succeeded in a trial at Paris on the 21st of October, 1797, though the parachute oscillated a good deal. On the [illegible] of September, 1802, Garnerin made a second descent, which was less successful than his first; he left St. George's Parade, North Audley Street, in a parachute thirty feet in diameter (one account says twenty-three feet), rose in about eight minutes to a height estimated at 4000 feet, and then cut the rope which attached him to the balloon. Unluckily the parachute remained closed, and for a few moments its motion was frightfully rapid; but at length it burst open with some violence, and the descent became gradual; the shock, however, had caused such an oscillation in the machine that it appeared to the spectators to be at times quite horizontal. But the vibration diminished as the parachute neared the ground, and Garnerin alighted safe in a field near the Small-pox Hospital in St. Pancras. But although safe, he was unable to speak, blood issued from his ears and nose, and he was in a state of great agitation; he had received a severe shock from the first rapid descent, and its sudden cessation; but the consequences were less serious than might have been anticipated, and he was well enough in a few minutes to address the crowds assembled to witness the attempt; the same shock had broken one of the stays, and this probably was partly the cause of the great oscillation. We are not aware that Garnerin ever repeated the experiment, but the writer of this notice in 1816 twice witnessed the descent of Miss Garnerin, his daughter, from great elevations; in both cases the fall was gradual and easy; and in one he saw her in less than a minute after she reached the ground, and before she left the car; she did not then appear in the smallest degree discomposed.

An unhappy and fatal experiment was recently tried in London by Mr. Cocking. This gentleman (incorrectly in our opinion) attributed the dangerous vibration of Garnerin's parachute to its general form; and supposed that if, instead of having the hollow side downwards, a parachute were made like an umbrella turned upside down, there would be no disturbance in its descent. He therefore made one in this form. The diameter was thirty-four feet, and as it would have a tendency to close in its descent, he endeavoured to prevent this by putting a heavy wooden hoop around it; it had also a hole in the middle six feet in diameter. The balloon to which this ponderous machine was attached left Vauxhall Gardens on the 24th of July, 1837, and the consequence was what might have been anticipated. As soon as the parachute was cut away, it fell with rapidity; its vibrations were violent, the large hoop broke, and Cocking fell, dreadfully mutilated, at Lee near Blackheath, about six miles from the scene of his ascent.

The result had nearly been equally fatal to the persons in the car of the balloon: the sudden liberation of the parachute caused such a rapid ascent that the gas was forced out with great rapidity, and for nearly five minutes they were so completely enveloped with it that for a time they were deprived of sight and suffered great pain. Most luckily they had provided a large silken bag full of atmospheric air and furnished with two metal tubes; these they applied to their mouths, and were thus enabled to breathe; without such a precaution suffocation would have been inevitable.

Three formulas have been given for calculating the velocity of descent of a parachute. They are—

$$26\sqrt{\frac{w}{d^2}} = v$$

$$28\cdot28\sqrt{\frac{w}{d^2}} = v$$

$$32\cdot98\sqrt{\frac{w}{d^2}} = v$$

in which w is the weight in pounds avoirdupois; d, the diameter of the parachute; v, the number of feet fall per second.

According to the first of these, if a parachute be 50 feet in diameter and weigh 529 lbs., it will fall 11·96 feet in a second; according to the second, the fall will be 13·01 feet; according to the third, 15·17 feet: the truth may lie between.

In these three cases, the shock felt on landing would be nearly equal to that caused by a leap from heights represented by the following three formulas respectively:—$10\cdot5\frac{w}{d^2}$; $12\cdot4\frac{w}{d^2}$; $16\cdot9\frac{w}{d^2}$; being, under the given circumstances, something less than 2 feet 3 inches, 2 feet 8 inches, and 3 feet 7 inches.

PARACYANOGEN. When cyanogen is obtained by heating bicyanide of mercury in a retort, there remains in it a dark-coloured substance, which was found by Professor Johnston to be similar in composition to cyanogen, that is, composed of 2 equivalents of carbon 12, and 1 equivalent of azote 14 = 26. It appears therefore that it is a bicarburet of azote, isomeric with cyanogen, but differing from it essentially in its physical and chemical properties, the paracyanogen being solid and cyanogen gaseous in its form. This compound is also formed when mercury is kept in an alcoholic solution of cyanogen.

Paracyanogen is soluble in sulphuric and nitric acids, and forms a compound in which an equivalent of oxygen is combined with 8 equivalents of carbon and 4 equivalents of azote: it is therefore probably composed of these proportions of the last-named elements.

PARADISE (παράδεισος) is a word of Persian origin, signifying a kind of park or pleasure-ground enclosed with walls, and well watered and planted, and stocked with animals for the chase. (Pollux, ix. 13; Gellius, ii. 19.) It was adopted into the Greek language, and applied to any pleasant place. The Septuagint translators use this word for גַּן־עֵדֶן, the *garden of Eden*, where God placed the first man upon his creation. (*Gen.*, ii. 8; iii. 23.) Respecting the situation of this place we are told, in *Gen.* ii. 8-14, that it lay eastward in the land of Eden, and that it was watered by a river, which, after passing through the garden, divided into four streams, of which the first, Pison, compassed the land of Havilah, where there was gold, bdellium (either the pearl or a sort of gum resin), and the onyx stone; the second, Gihon, compassed the land of Cush; the third was Hiddekel (the Tigris), which went towards the east of Assyria; the fourth was the Euphrates. Any attempt therefore to determine the site of Paradise must have for its object to find two other rivers which are so connected with the Euphrates and the Tigris that they all four may have been branches of one chief stream. Calvin, Bochart, and others attempt to solve the difficulty by supposing the words in *Gen.* ii. 8, to mean that the river which flowed through Paradise in one stream was formed by the confluence of two rivers where it entered the garden on the north (namely, the Euphrates and the Tigris), and that it divided into two others where it left the garden at the south, namely, the two mouths of the river formed by the union of the Euphrates and Tigris, now the *Shat el Arab*. On this hypothesis Cush corresponds to the present Khuzistan, the antient Susiana, or Kissia, and Havilah to the neighbouring part of Arabia, which in antient times did produce gold, and in which Strabo places a people called Χαυλοταῖοι (xvi. 767). Eden would then stand near the modern Korna, at the confluence of the Tigris and Euphrates. To this theory it has been objected that it uses the word Cush in a sense not supported by the other passages of Scripture in which that name occurs; that it is not clear that the *Shat el Arab* had antiently two mouths, and that if it had, such streams would not be spoken of as rivers of the same class as the Euphrates and Tigris; and lastly, that the interpretation put upon the words of *Gen.* ii. 8, is not a natural one.

Another theory places Paradise in the neighbourhood of Babylon, and finds the Pison and Gihon in two of the canals of the Euphrates.

Reland and Calmet place Eden in the high lands of Armenia, considering that the text (*Gen.* ii. 8) points to a position near the *sources* of the four rivers. They make the Pison the Phasis, the Gihon the Araxes (which is still called by the Persians *Jihon*), Havilah the land of Colchis, and Cush the country of the Cossæi (Strabo, xi. 522; xvi. 744; Diod. Sic., xvii. 111). The opinion of Michaelis is only slightly different from this; he takes the Gihon to be the Oxus. The Phasis of the antients however rose not in Armenia, but in Colchis.

Some writers suppose that the deluge has so altered the physical features of Asia, that it is in vain to search for a place answering to the description given in *Genesis*. But any one must perceive that the author of that book could have no object in writing the minute account which he has given of the position of Paradise, if some spot corresponding to his description did not exist on the face of the earth when he wrote. It must be admitted however that all the attempts hitherto made to discover the true position of the place are perfectly unsatisfactory.

(Winer's *Biblisches Realwörterbuch*, art. 'Eden;' E. F. C. Rosenmüller's *Handbuch der Bibl. Alterthumsk.*, i. [illegible] 172, &c.)

Paradise, in the New Testament, is used for the abode of the departed spirits of the good between death and the resurrection.

(Kuinoel, *Nov. Test. Lib. Hist.*, note on *Luke*, xx[illegible] Doddridge's *Family Expositor*, note on 1 *Cor.*, xii. 4. [illegible]ley's 26th *Sermon*.)

PARADISEA (Zoology). [Bird of Paradise.]

PARADISI, COUNT AGOSTINO, was the grand-nephew of Agostino Paradisi, author of the 'Ateneo dell' Uomo nobile.' He was born at Vignola, in the terri-

Reggio, April 25th, 1736, and was educated at the Collegio Nazareno at Rome, on returning from which he prosecuted his studies diligently, and among the rest, applied himself to that of English literature. His talent for poetry displayed itself at an early age, and when only sixteen he was admitted member of an 'accademia' at Reggio, where both his poetical compositions and his dissertations obtained for him great distinction. He afterwards visited Genoa, Venice, and Bologna, in which last place he became acquainted with the Marquis Albergati Capacelli, and shared with him in some of his dramatic compositions. On the death of the Abbate Salandri, in 1771, Count Firmian, the Austrian minister, invited Paradisi to accept the office of perpetual secretary in the academy of Mantua; but the duke of Modena appointed him professor of civil economy and lecturer on belles-lettres in the university of that city; and afterwards (1774) bestowed on him the title of count. During the eight years that he filled that chair, his lectures obtained for him the applause not only of his own countrymen, but of many eminent foreigners. In 1780 he returned to Reggio, where he held a distinguished civil employment, devoting his leisure to literary pursuits; but his health now began to decline, and he was attacked with dropsy in the chest, which disorder carried him off, February 19th, 1783, in his forty-seventh year.

Besides his '*versi sciolti*,' or poems in blank verse, which are esteemed both for their elegance of style and their moral value, he published three volumes of tragedies, translated from the French, including an original one entitled 'Le Epitidi.' Among his prose writings, his éloge on Montecuccoli is considered a masterpiece of its kind. His 'Saggio sopra l'Entusiasmo nelle Belle Arti,' shows his ability as a philosophical critic; while his knowledge of jurisprudence and civil economy is displayed in his 'Parere Economico' and other productions of that kind.

PARADOX (from *παράδοξος*, 'contrary to received opinion,') is a term applied to a proposition which is opposed to the general belief, or to one which appears at first sight to contradict some previously ascertained truth. The nature of a paradox and the distinction between it and a contradiction is clearly explained in the following sentence from Bishop Horsley's 19th Sermon:—'When two distinct propositions are separately proved, each by its proper evidence, it is not a reason for denying either, that the human mind, upon the first hasty view, imagines a repugnance, and may perhaps find a difficulty in connecting them, even after the distinct proof of each is clearly perceived and understood. There is a wide difference between a paradox and a contradiction. Both indeed consist of two distinct propositions, and so far only are they alike; for of the two parts of a contradiction, the one or the other must necessarily be false; of a paradox, both are often true, and yet, when proved to be true, may continue paradoxical. This is the necessary consequence of our partial view of things. An intellect to which nothing should be paradoxical would be infinite. . . . In all these cases there is generally in the nature of things a limit to each of the two contrasted propositions, beyond which neither can be extended without implying the falsehood of the other, and changing the paradox into a contradiction; and the whole difficulty of perceiving the connection and agreement between such propositions arises from this circumstance, that by some inattention of the mind these limits are overlooked.'

This word was also used by the Greeks for a remarkable saying. Cicero, in his work entitled 'Paradoxa,' illustrates six of these paradoxes, borrowed from the Greek stoics. These propositions are the following:—1, The honourable is the only good. 2, Virtue is sufficient for happiness. 3, All sins and right actions are equal. 4, Every fool is mad. 5, The wise man alone is free, and every fool is a slave. 6, The wise man alone is rich.

PARAFFIN. [Hydrogen—*Carburets*.]

PARAGUAY is a republic of South America, situated nearly in the centre of that continent, between 20° and 27° 30′ S. lat., and 55° and 62° W. long. It extends in length from south to north about 500 miles, and its average width may be about 200 miles. The area consequently may be estimated at about 100,000 square miles, or perhaps somewhat less; so that it covers a surface of about 16,000 square miles more than Great Britain. On its western side runs the Paraguay river, which divides it from the desert called the Gran Chaco, which is included in the territories of the federal republic of La Plata. On the east and south flows the Paraná, which separates it from the Brazilian province of S. Paulo, and from the state of Corrientes, which is a part of the republic of La Plata. On the north it borders on the Brazilian province of Matto Grosso, and in this part the boundary-line runs partly along the range of the Amambahy Mountains, and partly follows the course of the river Yvineima. The northern frontier however is not exactly determined, as the greater part of it is still in the possession of two independent tribes of natives, the Mbayas and Guaycurús, and no settlements of whites have been formed either on the side of Brazil or on that of Paraguay.

Surface and Soil.—The northern part of the country is mountainous. From the Serra Seyada, one of the mountain ranges which traverse the middle of Brazil from east to west, a branch detaches itself near 55° W. long. and 17° S. lat. This branch runs for some distance south-south-west, and then south, dividing the tributaries of the Paraná, which run east, from those of the Paraguay, which run west. This range is called Sierra Amambahy, and under that name it enters Paraguay near 20° S. lat. It continues in a southern direction to the vicinity of 24° S. lat., where it turns eastward and terminates on the banks of the Rio Paraná, opposite the Salto Grande de Sette Quedas. [Brazil.] This range is called Sierra Maracaju, where it runs west and east. That portion of Paraguay which lies on the east and north of this range is little known, as it is possessed by native tribes, and only occasionally visited by whites. It seems to have a very broken surface, exhibiting a succession of valleys and ranges of high hills, all covered with tall forest-trees. The rivers which descend from it are full of rapids and cataracts. The country west of the Sierra Amambahy seems to be less mountainous, but has likewise a broken surface, and its rivers run with great velocity, though their course is less interrupted by rapids. It is also well wooded, and in general of great fertility, but hitherto the whites have not settled in this part. Thus it may be said that one half of the countries included within the boundary of Paraguay, properly speaking, do not belong to it.

The remainder, or that part which is situated south of 24° S. lat., is one of the most fertile and most pleasant countries of South America. The greater part of the surface is a succession of hills and gently sloping eminences, and broad open valleys intersected here and there with lakes. The lower grounds and plains are in some tracts *savannahs*, and afford excellent pasture-ground; single palm-trees are dispersed over them. The hills and slopes however are wooded from the top to the bottom, and frequently with stately forest-trees. The vigorous vegetation shows the great fertility of the soil, which is still more evidently proved by the extent of cultivation. Though cultivation generally occurs only in detached patches and isolated tracts, it is certain that no part of the interior of America has so large a proportion of the soil under cultivation as the southern half of Paraguay. But there are some tracts less favourable for agriculture. Nearly thirty miles south of Assuncion begins a low tract of alluvial soil, which is covered with extensive marshes partly occupied by shallow pools of water. It is several miles in width, and extends along the Paraguay to its junction with the Paraná. Though in general destitute of trees, it is separated from the banks of the river by forests, which supply occupation to a small number of wood-cutters, the only inhabitants of this tract, who are frequently swept away by diseases engendered by the vapours which rise in hot weather from the swamps. Near the place where the Paraguay joins the Paraná the country is more elevated, and its surface is overgrown with thorny acacias and underwood of every kind. But along the Paraná other tracts of marshy ground of a similar description extend as far as the island of Apipé, from which to the Salto de Sette Quedas the hills and elevated ground come close up to the banks of the river. This latter tract however is less populous and cultivated than the centre and western part of the country, apparently not from want of fertility, but because it has not the same means of sending its produce to market.

Rivers.—The two rivers which enclose Paraguay on three sides differ greatly in their character as navigable rivers. The Paraguay is navigable in all its extent within this country, though its course is rather rapid at its northern extremity near the rocky barrier called Fecho dos Morros (21° 20′ S. lat.). [Brazil, v., p. 356.] Vessels of 200 tons burthen may ascend it as far as Assuncion, and smaller vessels several hundred miles within the boundary of Brazil. The Paraná, which runs along the eastern side of the country, is much less favourable to navigation. The great cataract, called Salto de Sette Quedas, near 24° S. lat. [BRAZIL, v.. 357], forms an insuperable impediment to navigation. Even lower down there occur several difficult passages, where the river descends in long rapids over rocky shoals; the last cataract occurs at the island of Apipé, where the river runs westward to its junction with the Paraguay. Vessels of 300 tons burthen ascend to this island to take in timber. Some of the smaller rivers which join the Paraguay, are navigable to a short distance from their junction with it, but one of them, the Tibiquari, is navigable above a hundred miles. It drains the southern portion of the country, and falls into the Paraguay near 26° 30′.

Climate and Productions.—Paraguay enjoys the advantages of the intertropical rains. The rainy season occurs in the months when the sun is in the southern hemisphere. The rains are far less abundant than nearer the equator, but sufficient to bring the fertility of the soil into full action. No meteorological observations have been published. In general the climate is said to be pleasant, and the heat rarely oppressive. The country is healthy, except the swampy tracts already noticed.

The principal articles cultivated as food are maize, batatas, mandioc, yucca-root, and beans. The cultivation of the sugar-cane, tobacco, and cotton is rather extensive. The principal fruit-trees are oranges and figs. With the exception of the yucca-root, the vegetables are bad, and consist chiefly of onions, capsicums, and garlic. Water-melons and musk-melons are abundant and good.

Paraguay possesses great wealth in its forests, which contain numerous species of lofty timber trees, and dye-woods for tanning and other purposes. Several of them produce gums and Indian-rubber, and others are used for cabinet-work. All the vessels that navigate the rivers Paraguay and Paraná are built of timber supplied by this country, and the ropes are made of the fibres of different plants which grow there, but it is said that they are soon spoiled by friction or water. The most remarkable of the trees is that which yields the famous herb called *maté*, or Paraguay tea [TEA, PARAGUAY], and which is extensively used in the southern countries of South America as a beverage. The country which separates the *yerbales* (or forests from which the leaf is procured) from the Paraguay is without cultivation, and covered with thorny trees intersected by marshy grounds.

As Paraguay does not contain such extensive prairies as those which occur in all the surrounding countries, the number of horses, mules, and cattle is not so great, but it is sufficient for the internal consumption. Most of the animals peculiar to South America are found in this country; and the monkeys commit great depredations on the fruit-trees and corn fields. Various kinds of birds, as parrots and paroquets, pheasants, toucans, humming-birds, and cockatoos, are numerous. The royal duck, or pato-real, is nearly as large as a goose, with a red and varied plumage. Wild bees are found in great numbers in the woods, and both honey and wax constitute articles of export. The large ants of this country have attracted the attention of naturalists on account of the extensive habitations which they build. The mineral productions are not known. According to the statement of the Jesuits, there is neither iron nor copper in this country.

Inhabitants.—The population of Paraguay is differently stated between 300,000 and half a million. In a few of the towns and their vicinity live a comparatively small number of whites, and a larger number of mestizos, or descendants of Spaniards and Indians. The latter have the air and appearance of descendants of Europeans. Both these classes understand and commonly speak the language of the Guaranis. This numerous tribe of aborigines, owing to the unremitting care of the Jesuits for a period of about eighty years, have almost entirely adopted the agriculture and arts of Europe, as far as they are fit for a nation inhabiting a country different in climate and other natural features. The Guaranis compose the bulk of the population, and in their manners and civilization approach nearer the whites who reside among them than any other of the aboriginal tribes of America: it may therefore be hoped that in course of time the whole population will coalesce in such a manner as to constitute one nation, by which all that animosity will be removed, which, in other parts of America, exists between the different races inhabiting one country. The political events which, in the last thirty years, have occurred in Paraguay, must greatly contribute to bring about such a union between these races. Some other tribes, as the Payaguas and Nalicunga, are dispersed among the Guaranis, but they consist of a small number of individuals.

Political Division and Towns.—The republic is divided into eight departments, called, after their capitals, Assuncion, Concepcion, Santiago, Villa-rica, Curuguaty, Candelaria, S. Fernando, and Santa Hermengilda. The capital of the republic is Assuncion, which is built near the banks of the Paraguay river, in the form of an amphitheatre. Properly speaking, the town consists only of one street of considerable length, which is surrounded by several lanes, and a great number of small houses, standing apart, and surrounded by groves of orange-trees. Most of the houses are small, even in the principal street, and consist only of a little shop with two or three apartments attached to it. The main apartment generally opens directly on the street, without any intervening passage. Few of the houses have flat roofs; the greater part are covered with tiles. The cathedral is a building without any pretensions. The government-house is an extensive edifice, but it has only one floor, and is built without taste. The best buildings of the town are a few convents. The inhabitants are mostly the descendants of Europeans and Indians; there are a few negroes, but not many mulattoes among them. The population amounts to about 10,000 souls. Some of the other towns are said to contain from 2000 to 4000 inhabitants, as Villa Reale de Concepcion, Villa-rica, Curuguaty, Cazapá, and Neembucu.

Commerce.—A country so fertile and so rich in vegetable products as Paraguay, besides being inhabited by a population accustomed to the wants of Europeans, might carry on a considerable commerce, and such indeed was carried on before its independence, when it had a free intercourse with Buenos Ayres and the other towns of La Plata. The exports from Paraguay to Buenos Ayres alone were then estimated at one million and a half of dollars, or 337,5[illegible]. They consisted of about eight million pounds of maté, or Paraguay tea, of one million pounds of tobacco, besides cotton, sugar, molasses, spirits, &c. As the countries farther south are either entirely destitute of trees or have no timber-trees, the exportation of timber was very considerable, and most of the vessels were built in Paraguay. But since Dr. Francia has become dictator, he has forbidden all commerce with foreign nations, and even with the neighbouring provinces, and he allows no one to leave Paraguay when he has once entered it.

History.—After the Spaniards had discovered the wide embouchure of the La Plata river, they sailed upwards, and tried to establish a colony on the banks of the river. But two attempts of this kind failed. The settlements contained only a small number of settlers, who were soon destroyed by the warlike natives of the plains. In 1535, the Adelantado, Don Pedro de Mendoza, was sent with a considerable number of vessels to found a great colony. He did not consider the naked countries on both sides of the river fit for such a purpose, and therefore he sailed up the Paraná and Paraguay for nearly a thousand miles, until he came to Paraguay, where he founded the town of Assuncion. From this place the Spaniards by degrees spread over all the countries of South America south of 20° S. lat. and east of the Andes. In the sixteenth century, the Jesuits were sent to those parts for the purpose of converting the natives to Christianity. Their success was not great until they obtained from the Spanish court a mandate (about 169[illegible]) forbidding all other Spaniards to enter their *Misiones* without their permission. The Jesuits settled among the numerous tribe called the Guaranis, on both sides of the river P[illegible], above the island of Apipé, and succeeded in bringing them to a certain degree of civilization. When the Jesuits were expelled, in 1767, the Misiones were inhabited by more than 100,000 civilised Indians, of whom perhaps less than one-half the number were in Paraguay. They afterwards dispersed through different parts of La Plata, but it seems that the majority settled in Paraguay, which after that time was entirely subjected to the viceroy of Buenos Ayres. In 1810, when a government was constituted in Buenos Ayres, independent of the then existing authorities in Spain, Paraguay refused to acknowledge this government, and defeated General Belgrano, who had been sent to bring Paraguay to obedience. The country soon after declared its independence. After some changes in the government, Doctor Gaspar Rodriguez de Francia became dictator; and though his measures do not agree with our conceptions of a wise government, he has preserved the country from all the misery which the other South American republics have constantly experienced in their continual dissensions and civil wars. His policy of excluding all foreigners from the country must contribute greatly to consolidate the different elements of the population into one mass, and to form them into a nation.

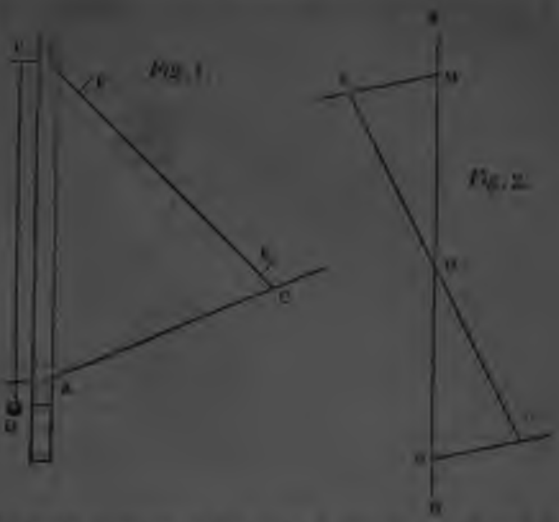
(*Parish's Buenos Ayres and the Provinces of the Rio de la Plata*; Robertson's *Letters from Paraguay*; Beaumont's *Travels in Buenos Ayres*.)

PARAGUAY TEA. [TEA, PARAGUAY.]

PARAIBA, or more correctly **PARAHYBA**, is a river in Brazil. It drains the littoral region of that country, which extends between 41° and 47° W. long. and between 21° and 23° 30′ S. lat., and is enclosed on the south by the Serra do Mar, and on the north by the Serra de Mantequeira and one of its branches called Serra do Frecheira. This river has a comparatively short course, but deserves notice because it drains the country lying to the north of the capital of the Brazilian empire, and is the first important river to be passed in proceeding into the interior of that country. The valley enclosed by the two ranges above mentioned is traversed longitudinally by a ridge of mountains of inferior elevation, called Serra do Parahyba. The river rises, where this inferior ridge is connected with the Serra do Mar, near 44° 30′ W. long., and flows, under the name of Parahytinga, westward, until, after a course of about 100 miles, and near 46° W. long., it turns north-east by a bend forming a very acute angle near the Aldea da Escada. As the river in this upper part of its course descends in a valley, the slope of which is considerable, the current is too rapid to admit any kind of navigation. From the Aldea da Escada the river runs east-north-east through a valley enclosed by the Serra de Parahyba on the south and the Serras de Mantequeira and Frecheira on the north, until it falls into the Atlantic about 20 miles north of Cape de S. Thomé, near 41° W. long. Its course in this valley exceeds 400 miles, so that it runs altogether above 500 miles. From the Aldea da Escada to the small town of Pindamonhangaba, a distance of 30 miles, the level part of the valley is some miles wide, and the current of the river rather gentle and regular, and it is accordingly navigated. Lower down however there occur several rapids and falls, as the valley grows narrower and the mountains approach close to the banks of the river. About 20 miles below Lorena, the bed of the river, which has enlarged to the width of half a mile, is contracted to about 10 yards by a long wall of rock on both sides, which is more than 40 feet high and 400 yards long. Farther down it receives the waters of two considerable tributaries, the Rio Parahybuna and Rio Pomba, each of which runs above 100 miles. The last of its numerous falls is that of S. Fidelis, which is somewhat more than 30 miles from its mouth, and to this place the current large river boats ascend. The greater part of the valley of this river is still in its natural state, being covered with trees of high growth, which more than in any part of Brazil exhibit that vigorous vegetation by which the maritime districts of that empire are distinguished. This is chiefly to be attributed to the great moisture of the air in a valley enclosed by mountains, and consequently not exposed to any wind. Cultivation has not yet made great progress, except in the wider portion of the valley, between the Aldea da Escada and Pindamonhangaba, where Indian corn and mandioca, as well as several other intertropical products, are raised, especially sugarcane and tobacco, for the cultivation of which the climate and soil seem very favourable. (Spix and Martius, *Reise in Brasilien*; Southey's *History of Brazil*.)

PARALLACTIC INSTRUMENT, or *Ptolemy's Rules*, the name given to an instrument invented by Ptolemy for determining the moon's parallax, and described by him, *Almagest*, lib. v., c. 12.

AB, BC, *fig.* 1, are two stout wooden rods turning on a pin, or centre at B; BA = BC; AC is a third divided rod, also turning on a pin at A, and passing through a loop at the extremity of the rod BC at C. PQ, a plumb line by which AB is adjusted vertically; E, F, two sights fixed on BC. It is evident if A B be truly perpendicular and any object be seen in the direction EF, that AC will be the chord of the angle ABC, that is, of the zenith distance of the object. AC may be divided as a scale of equal parts, and the angle deduced from a table of chords, or as a line of chords to radius A B, in which case the angle may be read off at once.*



A figure of a similar instrument may be found in Tycho Brahe, *Astron. Instaur. Mechanica*, sheet C. We have thought *Ptolemy's Rules* worth notice chiefly as pointing out a very cheap and accurate instrument for obtaining the time by the method of equal altitudes. Let A B be a rod turning on pivots above and below, for instance, between the sill and architrave of a window, and capable of being set perpendicular by a plumb-line, supposed in the figure to hang behind A B. E C, a stout edge-bar turning round a pin at O, and fixable in any direction by two laths, E M, C N. On E C a telescope is lashed (one sufficient for the purpose might easily be made of a tin tube and spectacle-glasses), with one or more horizontal wires placed in the focus. If the times of contact of the sun's limbs with the horizontal wires be observed in the forenoon and again in the afternoon (the axis A B being in both cases truly adjusted, and the instrument in other respects unchanged), the data will be obtained for finding the time shown by the watch when the sun is on the meridian, *i.e. apparent noon*, with great accuracy and very little calculation. (See Schumacher's *Hülfstafeln*, p. 40, &c.; Baily's *Tables*, pp. 32, 148, and many other collections.) The determination of the error of the watch by equal altitudes of the same star is even more simple, as there is then no motion in declination to be allowed for, and the middle time by the watch of similar observations is the time when the star passes the meridian, or its right ascension, which is known from the *Nautical Almanac*, or from well-known catalogues. The observer must be very careful to adjust the instrument by the plumb-line to the same position in both observations, and he must have a watch which will keep time correctly for the interval.

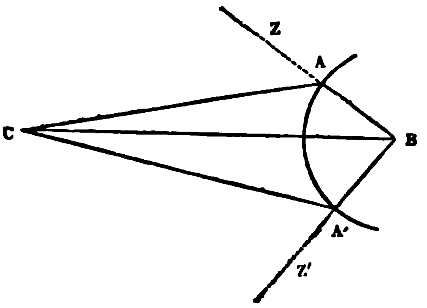
Sometimes the word *parallactique* is used to signify the instrument known to us by the name of EQUATORIAL. Lalande, *Astronomie*, § 2376, says the proper word is *parallatique*, or that which follows the *parallel* of stars; he reserves *parallactique* for *Ptolemy's Rules*.

PARALLAX, παράλλαξις, used in astronomy generally for the angular variation in the position of an object caused by the eccentric situation of the observer with respect to a certain point of reference. Thus the parallax of the moon, sun, planets, comets, is the difference between the position of any of these bodies as seen from the surface of the earth and that in which they would be seen if the observer were placed at the earth's centre. The parallax of the fixed stars is the difference between their places as seen from the earth and from the sun, which is for those observations the point of reference. All bodies within the solar system are in the first instance referred to the earth's centre; while those beyond our system, as the fixed stars, are referred to the centre of the sun, and the change arising from eccentric position in each case is called parallax.

From the effects of parallax we derive all our knowledge of the distance and magnitude of the bodies which are visible in the heavens.

---

* [illegible] Ptolemy's [illegible] He seems to have [illegible] the moon's parallax [illegible] of the earth's radii. [illegible]



Let AB be any line the length of which is accurately measured, and let the angles CAB, CBA, be observed, then the distances CA and CB can be computed. In this way trigonometrical surveys are made, with the further precaution that the angle ACB is observed when this is possible, and C is to be fixed with great nicety. The angle ACB is known, since it $= 180° - (BAC + ABC)$, and we have $AB : BC :: \sin ACB : \sin CAB$. In the above figure let A be the position of a spectator on the earth's surface, B the centre of the earth, C the moon, and Z (in BA produced) the geocentric zenith. Then ZAC is the apparent geocentric zenith distance at A; ZBC the true geocentric zenith distance, *i.e.* that which would be seen from the centre of the earth; and $ACB = ZAC - ZBC$, the moon's parallax· also

$$\sin \text{parallax} = \frac{AB}{BC} \times \sin \text{Appt. geocent. zen. dist.}$$

When AC is at right angles to BA this sine = 1 and the moon is in the horizon. This value of the parallax is called the *horizontal* parallax; naming this P, and any other value of the parallax p, we have $\sin P = \frac{AB}{BC}$, and

$$\sin p = \sin P \times \sin \text{appt. geocent. zen. dist.}$$

It is evident that if P can be measured, the distance R of the moon's centre from the centre of the earth can be found, for the other quantity AB or r is the radius of the earth at the place of observation, which is known from terrestrial measurement. Now suppose a second spectator on the same meridian at A′, whose geocentric zenith is Z′, and that the two observers each observe the moon upon the meridian at the same moment: then, if z and z' be two observed geocentric zenith distances, and p and p' the parallaxes, $P = \frac{BA}{BC} = \frac{r}{R}$, $P' = \frac{BA'}{BC} = \frac{r'}{R}$, and

$$\angle ABC = z - p$$
$$\angle A'BC = z' - p',$$

and adding $ABA' = z + z' - (p + p')$, where ABA′ is the sum or difference of the geocentric latitudes of A and A′, and z and z', are known by observation; hence the value of $p + p'$ or ACA is found. From the equations

$$p + p' = z + z' - ABA'; \ \sin p = \frac{r}{R} \sin z; \sin p' = \frac{r'}{R} \sin z';$$

it is easy to find the value of R.

In practice, though the process is less simple, the principle remains the same. Two distant observatories can scarcely be found exactly on the same meridian, but the tables of the moon enable us to reduce the observation at one of the observatories to exactly *what it would have been* if it had been made under the meridian of the other. When the parallax is small, it is advisable to compare the planet by the *micrometer* with stars which are nearly in its parallel. When the parallax and consequently the distance for any given time is known, the distance and parallax for any other time can be found from theory. By observations of this kind, combining the observations of La Caille at the Cape of Good Hope with other observations made in Europe, the parallax of the moon and of Mars were fixed with great accuracy. Mr. Henderson has recently investigated the value of the moon's parallax from a comparison of his own observations at the Cape with those made at Greenwich and Cambridge. (*Mem. Ast. Soc.*, vol. x., p. 283.)

It will be seen that the point from which the moon's zenith distances are to be measured is in the prolongation of a line drawn from the centre of the earth, and not in the prolongation of a line in the direction of gravity, which is pointed out by a plumb-line. The correction which is to be applied to the astronomical zenith, in order to find the geocentric zenith, is given in many collections of tables for a certain hypothesis of the figure of the earth. The horizontal parallax given in the Nautical Almanac is that which belongs to the equator where the earth's radius is largest. A second table for reducing this equatorial horizontal parallax to the parallax proper to the place of observation (viz. log. rad., supposing the equatorial rad. = 1) always accompanies that above referred to.

Parallax of the Sun.—The first attempt to determine the sun's distance seems to be due to Aristarchus of Samos, and presupposes the knowledge of the moon's parallax. On drawing a figure, it will immediately be seen that when the moon has completed her first quarter (she is then said to be *dichotomized*, or cut exactly in two), the sun, moon, and spectator form a triangle, which is right angled at the moon. Now the angle which separates the sun from the moon can be observed at the same instant: suppose it = E, we have—

Distance earth & sun = distance earth & moon × sec. E.

The exact moment of *dichotomy* cannot be noted with much accuracy; yet repeated observations would show that the sun was far more distant than the moon. The antient astronomers seem to have estimated the sun's parallax to be from 2′ to 3′, which suffered a gradual reduction as the means of observation improved. The parallax of the sun might with modern instruments be measured in the same way as that of the moon or planets above described, but not so well, as a longer time must elapse between the passage of the sun and that of a star nearly in the same parallel. Ptolemy says that Hipparchus computed the moon's parallax from the phenomena of solar eclipses, that is, he deduced the value of the moon's parallax from the phenomena of solar eclipses on two suppositions of the sun's parallax, namely, that it was = 0, and again that it was a definite small quantity. As the circumstances of a solar eclipse vary from the effects of parallax, it is clear that in this way Hipparchus would get something like equations of condition involving the parallaxes of the sun and of the moon, which could be solved as soon as, by the problem of Aristarchus or by any other method, he could determine the relation between these two quantities.

We have thus shown that an approximate knowledge of the distances of the moon, sun, and planets, in terms of the magnitude of the earth, requires nothing more than observation and the solution of a triangle one side of which and the two including angles are known. The magnitudes of these bodies can be immediately calculated from their apparent diameters and true distance; so that up to this point there is no room for scepticism, if it be granted that the angles of a triangle equal two right angles.

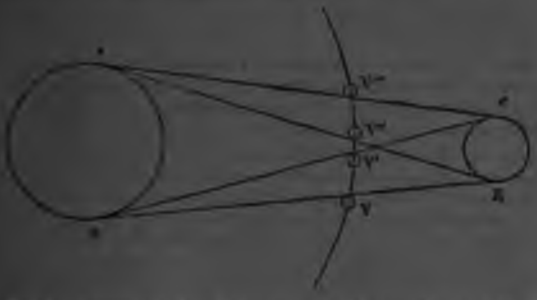
There is a method of ascertaining the parallax by one observer. Let Mars in opposition be the object, and compare it in right ascension with a neighbouring star in the same parallel on the meridian, and also several hours before and again after his transit. The parallax, being wholly in a vertical circle, will not affect the right ascension in the meridian: hence the meridian comparison will give the true difference of right ascension between the planet and star. The other observations (after correcting the place of Mars by his hourly motion, which is known either from the tables or from observations on preceding and succeeding days) present right ascensions of the planet affected by parallax in different ways, and from these effects it is easy to compute the actual value of the horizontal parallax, and consequently the distance of the planet in terms of the earth's radius at the place. The star of comparison and the hour angle must be so selected that no error can arise from the uncertainty of refraction. Similar observations which have parallax may be made with the altitude and azimuth circle; but these observations do not admit of much nicety.

Kepler's discoveries,* that the planets move in ellipses round the sun in the focus, that the area swept by each radius vector in a given time is a constant quantity for the same planet, and lastly, that the squares of the periodic times are as the cubes of the mean distance, have supplied means for a much more accurate determination of the sun's parallax. Assuming these laws, the *forms* of the orbits of the earth and planets and their *relative* distances can be determined from observation; hence, if the parallax of any one planet can be found, the parallaxes of the sun and of the other planets can be computed. Observations of Mars be [illegible], at his observations made at the Cape of Good Hope and at Greenwich, will afford a very tolerable value of his parallax and hence of his distance. Again as the proportion between the distances of Mars and the earth from the sun at any time is known from the form of their orbits and their periodic times, and the angle between the sun and Mars at the earth can be observed, the triangle between the sun, earth, and Mars can be completely solved, and hence the distance of the sun and his parallax be computed. These observations can be repeated at every opposition of Mars, and if Mars be compared by the micrometer with stars near the same parallel, there is scarcely a limit to the possible accuracy of the observations. In the *Naut. Alm.*, 1839, pp. 461-5?, there is a list of the stars with which Mars is to be daily compared at its opposition in that year. (*Mem. Ast. Soc.*, vol. ii., p. 27, and vol. vi., 297, &c.)

---

* Though these discoveries are due to Kepler, the satisfactory proof of their truth was given by Newton.

The observation however by which the parallax of the sun is determined with the greatest certainty, is that of the passage of Venus over the sun's disc, commonly called the *transit of Venus*. [Transit of Venus.]



In the figure let Ss be the sun, Ee the earth, and V and V′ two positions of Venus, which is supposed to be moving in the direction V V′. To make the figure simple, we suppose the earth to be at rest, and that V V′ represents the excess of the angular motion of Venus above that of the earth. A spectator at E will see the commencement of the transit when Venus is at V, but a spectator at *e* will only begin to see it when Venus is at V′. The time which must elapse between these two moments is equal to the time in which Venus passes from V to V′, or in which she describes the angle ES*e* round the sun with her *relative* angular motion. But the angle ES*e* is twice the sun's horizontal parallax; hence, since the time elapsed between the ingress at the two places is known from observation and from the difference of longitudes, and the hourly angular motions of Venus and the earth round the sun are known from the tables, and consequently the difference of these motions, the horizontal parallax of the sun can be found. It is evident that as the ingress is accelerated at E and retarded at *e*, so the egress will be accelerated at E and retarded at *e*, Venus then occupying the positions V″, V‴.

Let us suppose further that a spectator who saw the ingress at E, and therefore as early as possible, should by the rotation of the earth be carried to *e*, where he would see the egress as late as possible, while the spectator of the late ingress at *e* is in like manner carried to E, where he sees the earliest egress.* In the first case the time of the transit is increased as much as possible by the effect of parallax, and in the latter case it is equally diminished. Now suppose the parallax of the sun to have a certain value, the parallax of Venus and the effect of these parallaxes in increasing or diminish the duration of the transit for any specified places of observation can be computed. Hence when the durations are really observed, the differences between the observed duration and that which would have been observed if the spectator had been placed at the centre of the earth will fix the actual amount of the parallax. The especial excellence of this method consists in the accuracy† with which a particular phenomenon can be observed, namely, the first streak of light which is seen after the interior contact at ingress and the last streak before the interior contact at egress. Two points on the earth are chosen where the beginning and end are both visible, in one of which the duration is shortened as much as possible, while it is increased in the other. Every observation of either ingress or egress can in fact be used for determining the parallax, provided the longitude of the place of observation and the time be sufficiently well known; but where both the ingress and egress are observed, the duration alone requires care. Transits of Venus were observed in 1761 and 1769, and the parallax of the sun deduced by various computers. (Lagrange, *Mémoires de Berlin*, 1766; Encke, *Der Venus Durchgang*, Gotha, 1824.) The next transits will take place in 1874 and 1882.

In the preceding part of this article the methods of determining the parallaxes, and consequently the distances of the bodies composing our system, have been described, and we will now point out the way in which this knowledge is applied. Every observation of the sun, moon, or planets is affected by parallax and must be corrected for this previous to further calculation. All celestial bodies are apparently elevated by the refraction of the atmosphere, and those of our system are depressed by the effect of parallax. In nautical works there are tables for reducing the observed altitude of any heavenly body to its true altitude, *i.e.* to that which it would have if there were no atmosphere and the spectator were at the earth's centre. In most of the problems from which the longitude is determined astronomically, in solar eclipses, occultations, and lunar distances the great difficulty and trouble is in computing the effect produced by the moon's parallax. Astronomers have invented convenient *formulæ* for this purpose, according to the planes to which the bodies are referred. Thus in working out an occultation, the moon may be referred to the plane of the *horizon*, when the effects of parallax in altitude, and, if great accuracy be required, in azimuth, must be computed; or again, to the *equinoctial*, when the parallax in right ascension and declination is to be calculated; or finally, to the *ecliptic*, when the parallaxes in longitude and latitude must be found. The rules for these computations are given in treatises on Astronomy.

The mean equatorial horizontal parallax of the sun, according to Encke, = 8″.5776. Its true value for every ten days is given in the *Naut. Alman.* at the end of the ephemeris of the sun and moon. The equatorial horizontal parallax of the moon for mean noon and midnight is at page III. of each month, and the parallaxes of the planets are in the last column of the planetary meridian ephemeris.

One effect of parallax is, that the moon appears under a larger angle when near the zenith than when near the horizon. This is contrary to common opinion, but may be very easily proved experimentally, by any one who can handle a sextant with ordinary care. When the moon is in the zenith, the horizontal diameter may be *augmented from* 30″ to 40″. There is a table for this augmentation of the moon's semidiameter in most nautical works.

Constant of Parallax (*la constante de la parallaxe*) is the angle under which the earth's radius would be seen at the centre of the moon when she is at her mean distance. The radius chosen by La Place is that which belongs to a latitude of which the square of the sine = ⅓.

PARALLAX OF THE FIXED STARS. When Copernicus proposed his hypothesis of the earth's motion, one striking *astronomical* objection was, that the enormous displacement of the spectator's place which his system supposed was not supported by a corresponding change in the positions of the fixed stars. Every improvement in instruments, in the art of observing, or in the science of computation, seemed to increase the distance of the sun, and consequently the orbit of the earth, and still no sidereal change could be detected. Hence, until the discoveries of Newton brought forward physical arguments, of which however the conclusiveness is not immediately visible, the Copernican hypothesis was embraced on the grounds of its symmetry and simplicity rather than on demonstration. Opponents might always ask for the *experimentum crucis*, the effects of the earth's motion in the apparent displacement of the fixed stars, and this could not be supplied.

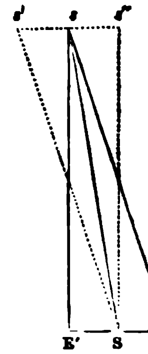
Many attempts were however made. Hooke erected a zenith sector at his chambers in Gresham College, and made some incomplete observations in which he fancied he could trace the effects of parallax. Flamsteed found variations in the north polar distances of fixed stars, which he attributed to parallax, although, as was shown by Cassini and Roemer, this would have produced results with a totally different law. Roemer himself, after many efforts to deduce parallax from observations in declination, renounced the attempt, on account, as he says, of 'a certain variation in the declinations of stars which can neither be attributed to refractions nor parallaxes,' and pursued his investigation by observations in right ascension, in which it seems he believed himself to be successful. At length Bradley commenced the research with far better astronomical means, and by his discoveries of aberration and nutation, fully explained the phenomena which had perplexed his predecessors. It is curious that Roemer, who had discovered the gradual transmission and finite velocity of light, should have been perplexed with the necessary results of this very property in another shape; and that Bradley, while pursuing the problem of parallax, which had been originally interesting as a proof of the earth's *change of place*, should have hit upon phenomena which satisfactorily proved the earth's *motion*, and so confirmed the Copernican hypothesis by evidence different from what he sought. Bradley's observations further showed that the effect of parallax in any of the stars observed by him could not amount to 2″ and probably was not 1″.

---

* The explanation is only intended to exhibit the principle on which this very important problem depends.

† This observation seems not to have been quite so delicate as was expected, a little uncertainty was introduced at the moment of interior contact before the formation of the thread of light, a sort of black drop (goutte noire). Mr. [illegible] has noticed [illegible] threads connecting the edges of the sun and moon [illegible] the formation and breaking up of the threads in the eclipse of May 15, 1836 (*Mem. Ast. Soc.*, vol. x. p. [illegible]), which seems to be a phenomenon of the same kind.

The nature of the changes in the places in the fixed stars, which the change of position in the earth would produce, may be seen from the following figure. Let S be the place of the sun, E that of the earth, and *s* that of a fixed star. Then the star is seen from the earth in the direction E*s*, and from the sun in the direction S*s*; the difference in these two directions is the angle E*s*S, that is, the angle of parallax. If S*s*′, *ss*′, be drawn parallel to E*s*, ES, and the observations made from the earth be referred, as observations of this kind are always supposed to be, to the sun, the true place of the star is at *s*, while the place which is assigned to it by observation is *s*′. At the end of half a year the place of the earth will be at E′, and the star is seen in the direction E′*s*. Hence it is referred to the position *s*″ in respect of S. It is evident that the effect of parallax is to cause the star to appear to describe an orbit round its true place in a plane parallel to the ecliptic, similar and equal to the earth's orbit round the sun; and further, that parallax is always in a plane passing through the star, sun, and earth, and that its effect is to diminish the angle which the sun and star subtend at the earth. When this is clearly conceived, it will also be seen that this ellipse, which is similar to the earth's orbit, will be seen obliquely from the earth, and consequently be projected into another ellipse with altered proportions. The same figure would serve for an explanation of aberration, except that aberration is in a plane defined by the star and the *direction* of the earth's motion, which direction is at right angles to the line joining the earth and sun, so that the *phenomena* of parallax and aberration are similar, only the effect of parallax is at right angles to the effect of aberration. This affords a convenient mode of computing the coefficient of parallax when that of aberration is known.*



There is another view of parallax. Suppose a spectator at the star *s*; then he would see the earth's radius vector SE under the angle of parallax. The earth's orbit may be considered to be circular, and as the plane is inclined to a spectator anywhere except in the pole of the ecliptic, the earth will appear to describe an ellipse about S as centre. The nearer the star *s* is to the ecliptic, the more excentric this ellipse will be,* but in all cases there is a diameter of the earth's orbit, viz. that which is perpendicular to the line joining S*s*, which is seen in its true proportions without foreshortening.

Since Roemer and Bradley, many astronomers have sought for parallax by observation in right ascension and declination. Bessel could find no evidence of such an effect in Bradley's transit or zenith distance observations. Piazzi, from meridian zenith observations, concluded that Sirius had a parallax of 4″ and Procyon one of 5″·7; Calandrelli found a parallax of 4″.4 in *α* Lyræ. But the most persevering and accurate observations for deducing the value of parallax from meridian observations were, not long since, prosecuted by Dr. Brinkley at Dublin with an 8-foot circle by Ramsden, and by Mr. Pond at Greenwich with the 6-foot mural-circle of Troughton. Dr. Brinkley conceived that he had established without doubt a sensible parallax in *α* Lyræ, *α* Cygni, and *α* Aquilæ, while Mr. Pond maintained that no sensible parallax was shown in any of those stars, from observations in declination and in right ascension. He further corroborated this result by comparing two stars, *α* Cygni and *β* Aurigæ, which have nearly the same declination and opposite right ascension, with a fixed tube. This controversy continued for several years, and though there can be no doubt *now* that Dr. Brinkley was mistaken, and that Mr. Pond was right in his conclusions, there is a good deal of interest attached to the discussion. Dr. Brinkley's last memoir is in the *Transactions of the Royal Irish Academy*, vol. xiv. Mr. Pond's paper on the parallax of *α* Lyræ will be found in the *Phil. Trans.*, 1823, part i., p. 53. A series of most excellent observations of *α* Lyræ were made at Greenwich in 1836, for the express purpose of ascertaining its parallax. After a careful discussion, Mr. Airy concludes that the annual parallax of *α* Lyræ, though undoubtedly existing in a quantity theoretically measurable, is too small to be made sensible to our most accurate meridian instruments. (*Mem. Ast. Society*, vol. x., p. 239.) Very careful transit observations by Bessel and Struve have shown that the parallaxes of all the stars they have examined in this way are so small as to leave the existence of any sensible parallax exceedingly doubtful. The only star in which parallax seems to be shown with great probability by meridian observation is the double star *α* Centauri. (*Mem. Ast. Soc.*, vol. xi., p. 61.) It may perhaps be sensible in Sirius, but the quantity is too small to be satisfactorily ascertained by such instruments. There are so many causes of error, and the whole quantity sought for is so minute, that we can scarcely expect a decided value of parallax to be shown by meridian observation. It is pretty certain that the diameter of the earth's orbit does not subtend a larger angle than 1″, at any of the stars hitherto examined, except *α* Centauri (it may be less in any proportion); so that the distance of these stars is at least 400,000 times the distance of the sun from the earth.

Sir William Herschel first pointed out the mode of detecting parallax which affords a probability of success, viz. that which depends upon the measurement of double stars. In his paper, *Phil Trans.*, 1782, part i., p. 82, he showed that if the stars which compose a double star be at different distances from the earth, which was at that time supposed to be the chief cause of differences in magnitude, they must be differently affected by parallax, and therefore that their apparent distance from each other will be altered by a change of position in the spectator. Now as the apparent distance of two neighbouring stars can be measured with great accuracy,† the problem of parallax is thus reduced to that of finding a double star in which a variation of distance is observable, and following the law which the earth's change of place requires. It was in this inquiry that Sir William Herschel discovered that very many double stars have a relative motion both in distance and angular position, which proves them to be a connected system, and that unexpected result, which he prosecuted with all his ardour and genius, seems to have led him from the investigation of parallax into his profound and original researches. Sir John Herschel (*Phil. Trans.*, 1826, part iii., p. 266) extended his father's proposal for the discovery of parallax by show-that the variation produced by parallax in the angle of position of two stars is a more sensible phenomenon and one more easily measured than the variation in distance; and in the *Phil. Trans.*, 1827, p. 126, he published a considerable list of stars suitable for this research, with the times of year when the observations would show the greatest effect of parallax.

---

* This similarity between aberration and parallax is not rigorous, but nearly so. It would be strictly true if the earth moved uniformly in a circle. There are convenient tables for computing aberration for a given constant of aberration. Calculate the aberration by these tables for ☉ + 90°, ☉ being the sun's longitude at the time, divide by the seconds of the constant of aberration, and you have the coefficient of parallax, the parallax being supposed = 1″. Also the times when the parallax in right ascension or declination is the greatest possible will be when the effect of aberration in those directions is 0, and versa vice.

* The semi axis major is the earth's radius vector, and the semi axis minor is the earth's radius vector × sin of *s*'s latitude.

† It is perhaps more easy to determine the distance of a double star to a ·1 than to fix an absolute place to 1″.0.

It has been shown that the earth's change of place in its orbit causes each star to have an apparent motion in an ellipse of which the major axis is parallel to the ecliptic and equal to the diameter of the earth's orbit as seen at the distance of the star, and the minor axis equal to the major × sine ☆'s latitude. If then the stars be a connected system, and comparatively near each other, the stars will appear to describe two equal and similar ellipses, and the line joining their apparent places will be equal and parallel to the line joining their *true* positions. It is therefore in vain to look for any effect of parallax in micrometrical or relative measures of distance and position in a connected system. But if one of the stars be much farther from us than the other, suppose it ten times farther off, then the apparent ellipses will continue to be similar, and similarly described, only the dimensions of that described by the more distant star will be 1-10th of that star described by the nearer, which comes to the same thing as supposing the more distant star to be fixed, and the nearer star to describe round its true place an ellipse of 9-10ths the actual dimensions. If with Sir William Herschel we measure the apparent *distances* of the two stars, those are best suited to the purpose in which the line joining the stars is in the direction of the major axis of the parallactic ellipse, *i.e.* is parallel to the ecliptic. If we proceed by measures of position, as recommended by Sir John Herschel, those stars are most favourable in which the line joining the two stars is perpendicular to the ecliptic. It is scarcely necessary to say that these conditions are not rigorous, and that stars tolerably near the pole of the ecliptic are equally well suited to either kind of measure, as the apparent ellipse is then almost a circle. Since the application of clock-work to large equatorials, we think that the measures of distance of double stars may be made nearly as accurately, and even more easily, than angles of position; and further, that any telescopes which have yet been constructed may be mounted equatorially and carried by clock-work. Most of the close double stars are probably connected, and are therefore unfit for the detection of parallax. Again, when the distance exceeds a few seconds, measures with the wire micrometer and with high powers are not satisfactory, for the eye in delicate measurement must see both stars at the same glance. The number of stars apparently double in which parallax is likely to be found, and so close as to admit of accurate measurement with the wire micrometer, is probably very small: happily there is another instrument of equal accuracy with the wire micrometer, and of wider grasp, which can be applied to this research, the heliometer. [MICROMETER.] The heliometer will measure thousands of minutes as easily as the wire micrometer can measure seconds.

In the last named property, that of measuring considerable angles, the heliometer is unrivalled, and thus we see its special use in the researches connected with parallax. It is almost hopeless to attack the problem by any other means at present known; and the divided eyepiece, which is found very useful for *small* measures of distance, is, like the wire micrometer, *limited* in this respect.

For his researches on parallax, Bessel selected the remarkable star 61 Cygni, which is a double star having a large proper motion. This property leads us naturally to guess that it is a comparatively near star, as its actual velocity would otherwise be enormously large. Two stars *a* and *b* were chosen, *b* in the direction joining the component stars of 61 Cygni, and *a* at right angles to this direction. The observations of *b* are made by bringing it into the middle of the two stars, those of *a* by placing it in the same line with the two stars. As the two stars of 61 Cygni are nearly of the same brightness, the observation is exceedingly accurate. These measurements were continued for fourteen months with very little interruption. The stars *a* and *b* are so far removed from 61 Cygni as to render any connexion with it improbable. Variations were found in these distances, which, being compared with the effect which parallax would produce, are *exactly* accounted for; therefore this variation is produced by parallax, for it can be shown that any other *known* cause of disturbance has been got rid of by the skill of the observer. The result is that the parallax of 61 Cygni is 0″·314; whence the distance of 61 Cygni is 656,970 times the distance of the earth from the sun, and light from the star is 10¼ years in reaching us. Though subsequent observations may modify this result, there is no probability that it will undergo any considerable alteration. (*Astron. Nachrichten*, N. 365, 6.) There is a second memoir not yet published. For Struve's inquiry into the subject of parallax, see his splendid work *Stellarum Duplicium et Multiplicium Mensuræ Micrometricæ, &c., annis à 1824 ad 1837 institutæ*, p. clxix, where he enters very fully into this subject.

PARALLAX, ANNUAL, is the angle under which the earth's orbit is seen by a superior planet.

PARALLAX, in practical optics, is the longitudinal misplacement of the wires in a telescope or microscope. If the wires are not at a proper distance from the object-glass, the image of the object is not seen distinctly when the wires are so seen. On giving a little motion to the eye, the object will seem to move upon the wires. If it moves in the direction of the eye, the cell carrying the wires must be pushed in, and *vice versâ*. There are means for this adjustment in all instruments which require it, and it is a point to which the attention of observers should be very carefully directed.

PARALLEL ROADS OF GLEN ROY. Glen Roy and several other valleys of the Highlands of Scotland exhibit very distinctly a series of parallel and nearly horizontal lines, embracing the sides of the hills and entering many of the lateral glens, at levels from a few to several hundred feet above the general bed of the valley. The important evidence which these elevated terrace-lines bring to the solution of questions regarding the origin of valleys, the dispersion of alluvial and diluvial detritus, and the subsidence or elevation of large tracts of land, induces us to present a critical examination of the state and progress of geological investigation on the subject. We have seen and examined Glen Roy; but the principal information in the following notice is gained from Dr. MacCulloch, Sir T. Lauder Dick, and Mr. C. Darwin.

Glen Roy is a valley in the district of Lochaber, whose headwaters gather on a wild mountain tract near the source of the Spey. The water of Roy runs nearly south, and joins the Spean, which turns westward to enter the 'great valley' of Scotland, below the south-western extremity of Loch Lochy. Passing from Fort William to the foot of Glen Roy, we have porphyry, gneiss, mica schist, primary limestone, and quartz rock, much disguised by diluvial accumulations. Glen Roy divides, not indeed exactly, the mica schist and gneiss systems, the former predominating on the western and the latter on the eastern side. About the source of the Spey is a limited tract of granite; and the low summit of drainage between Glen Roy and Glen Spey is formed of this rock. From this flat and boggy summit the descent is gradual to Loch Spey on the east, and sudden into Glen Roy on the west. Upper Glen Roy, as MacCulloch terms the part near the head, is an oval valley, about four miles in length and one or more in breadth, and bounded on two opposite sides by high mountains, yielding two streams from the north-west and south-east, which meet near the middle of the valley. From their junction the united water of Roy flows in a gradual manner to the south-west for about two miles, when the valley contracts to a low rocky pass, in which the river runs a troubled course, and then emerges into the wide and long and rather sinuous valley of Lower Glen Roy. At the extremity of the rocky gorge which separates the upper from the lower glen, MacCulloch directs attention to a remarkably flat rock; and observes that above this gorge, in Upper Glen Roy, no distinct *terrace* or *shelf* was seen, but a *line* was noticed extending from near the junction of the streams which form the Roy towards Loch Spey; and it was proved by the spirit-level that this *line* was level with the remarkable flat rock at the gorge which terminates Upper Glen Roy, and also with the uppermost of three such lines, terraces, or shelves in Lower Glen Roy. (Both Sir T. Lauder Dick and Mr. Darwin represent this upper *line* as being traceable all round Upper Glen Roy to near the edge of Loch Spey.) Passing from Upper to Lower Glen Roy, the single line of Upper Glen Roy ascends from the valley and girdles the sides of the hills right and left, with seemingly higher and higher sweeps, and is followed by two other perfectly parallel and equally continuous lower lines, till Glen Roy expands into Glen Spean. Here the *two upper lines end;* but the lower one appears on the north and south sides of Glen Spean as far towards the source of the river Spean as the singular pass of Muckul, and turns southward a little way up the Gulban river, and still farther along the sides and round the head of Loch Treig. In a westward direction this line continues down Glen Spean on both sides, about half the distance from the Roy to the Lochy, and then ceases; nor has it been noticed in the Great Valley between Fort William and Inverness. Another line however, a few feet higher than the highest in Glen Roy, appears in the upper parts of Glen Gluoy, which, running parallel to Glen Roy, enters Loch Lochy. Mr. Darwin notices a *line* in another smaller tributary to Loch Lochy, near Kilfinnin; and describes a short terrace which appears on the south side of Loch Spey, about sixty feet above that lake, and higher than the highest terrace of Glen Roy. Sir D. Brewster has also observed shelves resembling those of Glen Roy in a part of the valley of the Spey, several miles below its source.

The elevation of these lines above the sea is known approximately, but not with the exactness demanded by a phenomenon so curious in itself and so fertile of subjects for geological speculation. In the following table we have combined the statements of MacCulloch, Sir T. Lauder Dick, and Mr. Darwin. The last writer thinks Dr. MacCulloch's measures of the terraces in Glen Roy 100 feet in excess.

Relative levels of the various lines in Scotland:—

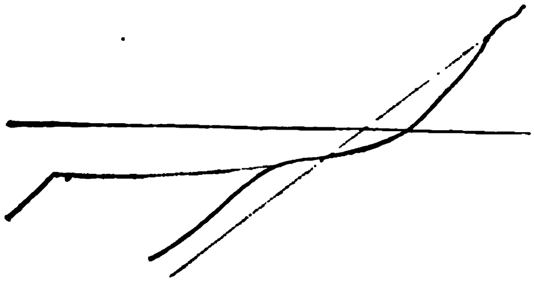
	Darwin.	Dick.	MacCulloch.
South of Loch Spey*	..	..	..
Kilfinnin . . .	1202	..	1302†
Glen Gluoy. . .	..	292	1274
Upper Terrace, Glen Roy	1162	280	1262
Middle Terrace, Glen Roy	..	200	1182
Lower Terrace, Glen Roy	..	0	972
Loch Lochy . .	82	..	..
The sea at Loch Eil .	0	..	0

The *lines*, *shelves*, or *terraces* (for each of these names is locally appropriate) must not be confounded with the more ordinary occurrences of short successive level terraces of gravel, or with the *longer* declining gravel banks which margin the sides of many valleys where they pass from the mountains to plain countries or the sea; they should be distinguished also from the similar little terrace heaps which often appear at the summits of drainage in mountain countries. Such gravel terraces are seen both at the summit and at the foot of Glen Roy, and in each case appear intelligible as the result of fluviatile action at higher levels than the present water-channel.

The *lines* of Glen Roy and the other valleys are not short protruding terraces connected with the several lateral affluents, nor declining planes of gravel, but almost perfectly continuous shelves, sloping toward the valley from a level line, and almost perfectly parallel through all the various windings of their linear extent, and round the hollows and projections of the hills, whether these are small or great, sudden or otherwise; and each respective range, on one side of the glens, is exactly on the same level with that corresponding to it on the other side. This almost perfect horizontality and continuity of range is the grand feature of the phenomenon, and though easily admitted on ocular inspection, it is satisfactory to know that Sir T. L. Dick has *proved* it by careful levelling with Mr. Maclean on each of the 'shelves' in Glen Roy. With such characters it is not wonderful that these mysterious works of nature should be supposed the effect of art, and the term of 'Parallel Roads' is far from inapt, and is certainly very descriptive.

The 'shelves' generally appear distinctly and even sharply defined when viewed from below or from a distance; but when inspected more narrowly, they appear very indistinct, and one may actually be treading on a shelf without being aware of it. This arises in a great measure from the fact that the surface of the shelves is far from level, but being often a little concave above and a little convex below, easily on a near view loses itself in the general slope of the mountain.

Sir T. Lauder Dick represents the general figure of a section of the shelf thus:—



Dr. MacCulloch gives many representations on a small scale, which show the really sloping character of the shelf or terrace, the angle of declination from the horizon varying from 12° to 30°, while the breadth of the terrace part varies from 10 to 70 feet; where the slopes of the 'lines' are steepest their surface is narrowest, and generally where the ground slopes the least the terraces are the broadest. A real profile of one part is given below by the black line.

According to Mr. Darwin's view of the relation between the actual form and the original outline of the fundamental rock, one part will appear to be formed by *excavation* of the rock, and another part by accumulation of detritus, very slightly projecting beyond the slope of the mountain. MacCulloch's drawings indeed represent the shelves as hardly in any case projecting into a mound. Another part is drawn to represent a valley terrace composed of gravel, to which the shelves (where they cross valleys) occasionally unite on a level, and thus form broad expansions.

'The shelves entirely disappear when crossing any part of the mountains in which the bare rock is exposed; for loose matter cannot accumulate there, and the rocks themselves, from their laminated structure, do not readily become worn into any regular form. They likewise disappear when crossing any part which is greatly inclined; for their own slope then coincides with that of the alluvial covering, and cannot be distinguished from it.' (Darwin.)

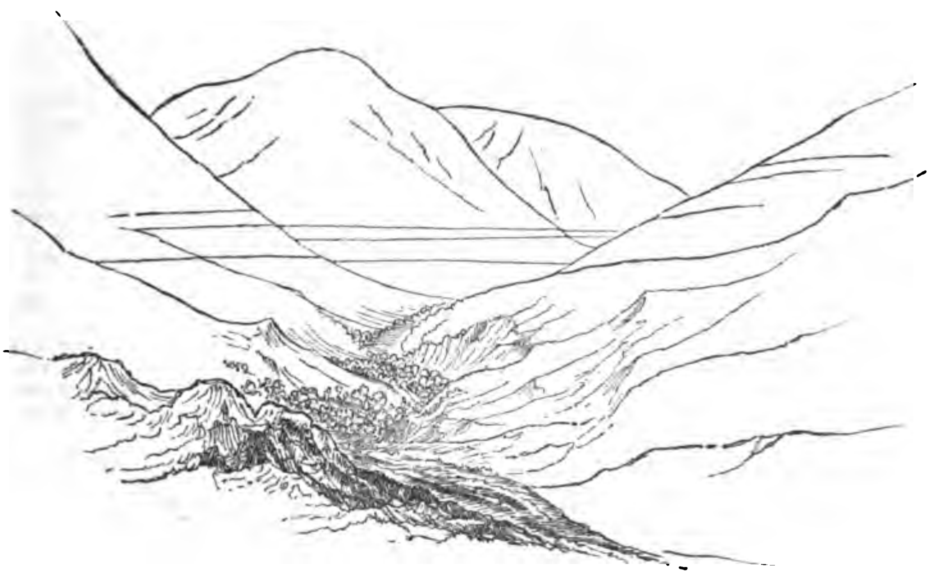
The actual surface of the shelves is very irregular; they are composed of the same kind of alluvium with that covering the whole surface of the mountain. (Darwin.) They commonly contain rounded pebbles, and are in many places covered with large masses of stone, some of them many tons in weight, lying for the most part quite detached on the surface, and having their acuter angles rounded off in the greater number of instances; in short, *in every respect resembling those fragments generally found strewed on the margin and on the shallow edge of alpine lakes.* In some places, where the stones are large and the shelf narrow, a single block covers its whole breadth. When rock appears anywhere on a shelf, its angles are also rounded. (Sir T. L. Dick, from whom the above description is taken, states that the soil above the highest line of shelf is materially different from that below, which has more gravel, pebbles, and alluvial clay; but Mr. Darwin's subsequent observations do not confirm this.) The cases are few in which the solid rocks are much worn away in this manner; indeed they are not visible on the shelves. Some of the blocks of stone on the shelves have fallen from the heights above; others belong to far removed sites, and are in fact *erratic boulders*. Among these latter are large granite blocks.

It must be evident, from the foregoing description, that the parallel roads of Glen Roy, and the lines resembling them or connected with them in the neighbouring regions, are marks of the antient level of water filling the valleys to their summits or nearly so, and extending towards their mouths till within a few miles of the sea, or the great interior valley of Scotland. As many *lines* as we see, so many successive effects are there of water oscillating about particular levels through all the extent of the lines. This is freely admitted by all writers and all observers on the subject. Sir T. L. Dick, who gives abundance of illustrations of similar shelves being actually formed on the steep sides of modern lakes, adopts the hypothesis which most easily and obviously suggests itself, and ascribes the lines in all the valleys to the operations of a lake whose waters were successively lowered. Dr. MacCulloch discusses very ably two other modes of watery action whereby the lines may be supposed to have been formed; first, by a sort of local deluge filling the valley; secondly, by the excavating power of water in a valley previously filled by alluvial sediments to a particular height; and shows each hypothesis to be unsuitable and untenable.

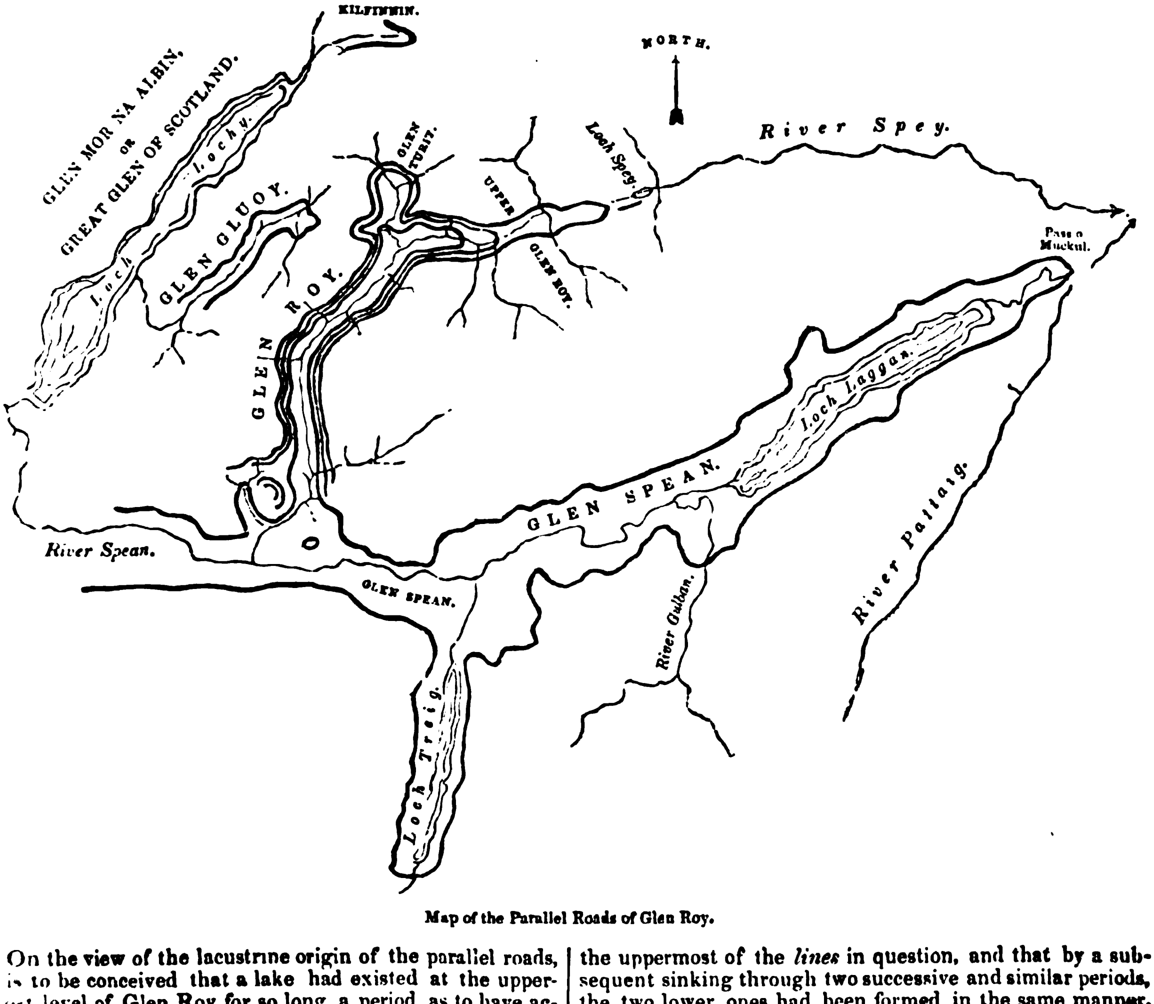
---

* Mr Darwin says this is 60 feet above Loch Spey, but he does not state the height of the upper terrace of Glen Roy above that loch. MacCulloch supposes it to be the continuation of the upper level of Glen Roy. He says Loch Spey is 1203 feet above the German Ocean, and that the upper line in Glen Roy is 6[illegible] feet above Loch Spey.

† This number is supplied by adding the partial results of Darwin to MacCulloch's general scale.



View of the Parallel Roads of Glen Roy. Sketched from nature, in 1826, by Professor Phillips.



Map of the Parallel Roads of Glen Roy.

On the view of the lacustrine origin of the parallel roads, it is to be conceived that a lake had existed at the uppermost level of Glen Roy for so long a period as to have accumulated on its margin that alluvium which now forms the uppermost of the *lines* in question, and that by a subsequent sinking through two successive and similar periods, the two lower ones had been formed in the same manner. (MacCulloch.)

Connecting the whole subject in one view, Sir T. Lauder Dick supposes that Glen Gluoy was antiently filled with a lake discharging itself by a short stream into Glen Roy, which, at the time of the formation of its upper shelf, was filled by a lake level with the summit of the drainage of the Spey, into which its superfluous water ran, and extending thence to the sides of Glen Spean (then filled with water), but separated from that glen by a barrier afterwards in part removed. By such partial removal, the level of water in Glen Roy sunk 80 feet, and still the lake in Glen Roy was distinct from that in Glen Spean. Finally, by a further removal of the barrier, the level of Loch Roy, as we may term it, was lowered 200 feet more, to that of Loch Spean. As in this view Glen Gluoy and Glen Roy are supposed to have discharged their waters in the direction where now are the heads of the lakes, so Loch Spean is supposed to have done this by the pass of Muckul, eastward to the Spey, and not westward to Loch Linnhe. By a subsidence at the former head of Loch Roy, its waters no longer flowed to Glen Spey, but to Glen Spean; by a similar subsidence at the former head of Loch Gluoy, its waters were turned to Loch Lochy; and by a similar effect at the former head of Loch Spean, its waters turned from the Spey to the westward.

We may further imagine, at what is now the lower end of Glen Roy, either a great subsidence of the land, or a wearing away of a narrow and weak barrier left between it and Loch Spean; the latter is the hypothesis of Sir T. Lauder Dick.

If now it be supposed that, parallel to the then upper (western) ends of Glen Spean and Glen Gluoy, a general subsidence happened, the entire change of the current of water from its former to its actual state, from an eastward to a westward direction, and the entire drainage of these supposed lochs, follows of course.
